Disadvantages.—Difficulty in localising faults. Steel armouring liable to be attacked by salts or acids in the subsoil. Armouring practically no protection against spikes and picks. Highly susceptible to electrolytic troubles.

LAID SOLID IN TROUGHS FILLED WITH BITUMEN.

Advantages.—High insulation between lead sheath and earth. Freedom from electrolytic troubles. Excellent for distributors.

Disadvantages.—Difficulty in localising faults. Provides no means of increasing the capacity of feeders, and consequently entails a very heavy and to some extent unnecessary expenditure on copper when the earning powers of the undertaking are small. As the ultimate requirements are usually

Digitized by Google

underestimated, the streets have often to be reopened to lay another feeder.

DRAWN INTO IRON PIPES.

Advantages.—A faulty length of cable is easily drawn out and replaced by a sound length. Spare ways may be laid to provide for extensions.

Disadvantages.—Pipes rust very quickly, and if cable is protected with braiding a rust joint soon forms between the braid and the interior of the pipes, entirely preventing the withdrawal of the cable. Lead sheathing being uninsulated from earth, the strain on the insulation between conductors and earth is greatly increased. Liable to electrolytic troubles unless pipes are efficiently bonded throughout.

COMMON EARTHENWARE PIPES LAID DIRECT IN GROUND.

Advantages.—Cheap.

Disadvantages.—Impossible to keep watertight, therefore increased strain on insulation, and electrolytic troubles are almost certain to cause cable to break down in course of time. No protection against picks, etc.

MOULDED CONCRETE.

Advantages.—Affords good mechanical protection to cables.

Disadvantages.—Impossible to keep watertight, therefore ultimate damage to cables liable to be as great as in the case of common pot pipes.

HIGH-CLASS EARTHENWARE DUCTS.

Advantages.—If well laid on a solid bottom, and all ducts are carefully examined for cracks before laying, a dry conduit may be secured.

Disadvantages.—Insufficient mechanical protection. Liable to be rendered inefficient by any subsidence of the subsoil.

HIGH-CLASS EARTHENWARE LAID SOLID IN CONCRETE.

Advantages.—Undoubtedly constitutes, when well laid, an excellent conduit system.

Disadvantages.—Very high first cost. High percentage of breakages. Ducts can only be obtained in short lengths, entailing a large number of joints. Cost of laying very high. Cost of cartage and handling high.

ORDINARY BITUMEN DUCTS.

Advantages.—Efficient insulation between lead sheath and earth is secured.

Disadvantages.—The heating of the conductors due to C^2R losses causes the cable to stick to the ducts, with the result that the cable can often not be drawn out, and the great advantages of a drawn-in system are consequently lost.

FIBRE CONDUIT LAID SOLID IN CONCRETE.

Advantages.—The cost of this system is considerably less than that of a high-class earthenware conduit, even when the latter is laid direct in the ground. Excellent mechanical protection is secured, and there is no risk of injury from subsequent disturbance of the ground. The conduit is an excellent insulator, and is absolutely watertight. The strain between conductor and earth is, therefore, reduced to a minimum, and electrolytic troubles are entirely overcome. It is very simple to lay. One man has laid over 6,000ft. in 10 hours. It is very light, and the cost of cartage and handling is consequently low. It is entirely unaffected by salts or acids. It is tough and mechanically strong. The percentage of breakages is in consequence very small. It is supplied in 5ft. lengths. It does not become sticky with a rise in temperature. Experience has shown that cables that have been laid some years can be drawn out as easily at the end of that time as they can be drawn into a new earthenware conduit.

Disadvantages.—Is not quite so cheap as a common earthenware pipe.

The system last referred to is comparatively new in this country, though it has been used in the States for about 10 years. It was first brought to the writer's notice a few months ago, and he has since persuaded a number of engineers in this country to lay some trial lengths, and they all, without exception, report favourably upon it. The conduit is composed of a mixture of wood fibre, bitumen, and paraffin wax, the method of construction being such that all ingredients are thoroughly mixed in the exact proportions which long experience has shown to best meet the conditions required. Each length of conduit has spigot and socket joints that fit perfectly into each other, making an excellent joint of the same external diameter as the rest of the pipe.

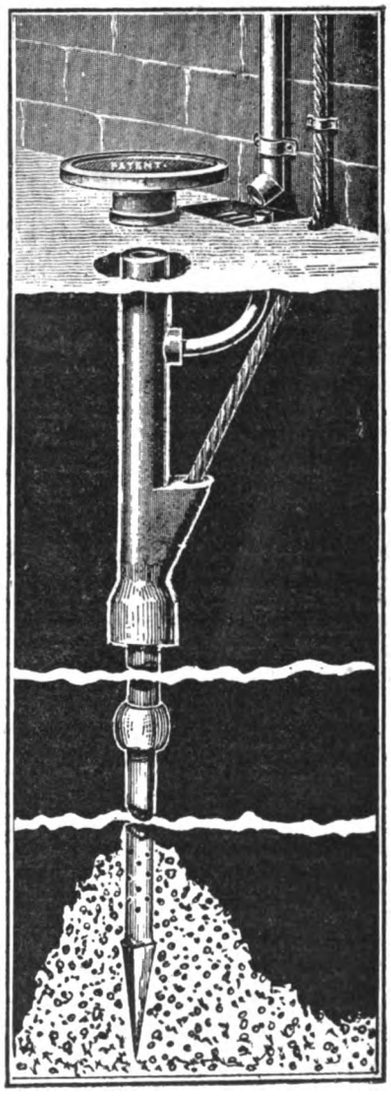
The method of construction employed in New Jersey, where over 260,000ft. of this conduit have been used, was as follows: After the excavation was made a bed of concrete was placed on the bottom of the trench, then a line was drawn taut on one side, next to which was laid the first line of duct. The remaining lines of duct were laid parallel to the first and separated ½in. from each other by means of wooden pegs. After the first layer was laid, it was covered with concrete and well grouted, sufficient concrete being used to cover the first layer to the depth of ½in. The succeeding layers were laid in exactly the same way. The majority of the ducts were laid in five layers of six ducts per layer. Owing to an obstruction, a portion of the system was laid in two layers of 15 ducts per layer. This was an exceptionally difficult installation, owing to the large quantity of water present necessitating the frequent use of an electrically-driven hydraulic pump. Even though the conditions were unusually severe, the contractor made a record, one man in the trench and two helpers above laying over 15,000ft. of duct (nearly three miles) a day, exclusive of concrete.

A heavier build of fibre conduit with screwed couplings is largely used for laying single-way ducts directly in the ground, in positions where the cost of concrete would be prohibitive.

TRADE NOTICES AND NOVELTIES.

Hedges's Tubular Earth.

The accompanying illustration shows the arrangement of Mr. Killingworth Hedges's patent tubular earth for lightning conductors, known as the "Air-to-Earth" system. This earth has three principal parts—the upper, which is electrically connected to the cable or tape; the lower, which forms the actual earth; and the cap marking the position. To sink it, the perforated steel-pointed end is attached to a length of wrought-iron pipe fitted with barrel-shaped sockets. A driving-piece is then screwed into the top socket, and struck by a sledge-hammer, other lengths of pipe being added and driven down in a similar manner until moist ground is reached. This done, the conductor is threaded through the projecting piece of the cast-iron top, and dropped to the bottom of the tube, which is then filled up completely with granulated charcoal or carbon. The top piece can then be lowered, and the electrical connection made in the same way as the joint of a water or gas main, by molten lead and caulking. With the cap which marks its position in place, the earth is then complete, but in order to render it permanent a ¾in. or ¾in. gas-pipe is led from one of the holes in the top piece to the



Digitized by Google

nearest rain-water pipe. Where there is no rain-water pipe handy, the earth can be kept damp by occasionally lifting the cap and pouring water down the tube that way. It is claimed that the conductivity of this earth is perfect and constant, while the first cost is less than for the plate earth, which latter has, moreover, to be tested periodically. It remains to add that the device has been used at a large number of public buildings and elsewhere. The licensed makers are the Carboid Company, 1, Emery-hill-street, Ashley-gardens, Westminster, and the General Electric Company, Limited, of whom further particulars may be obtained.

Crypto Electrical Specialities.

The accompanying illustration, Fig. 1, shows a "Crypto" induction motor, which is "special" in that the starting is

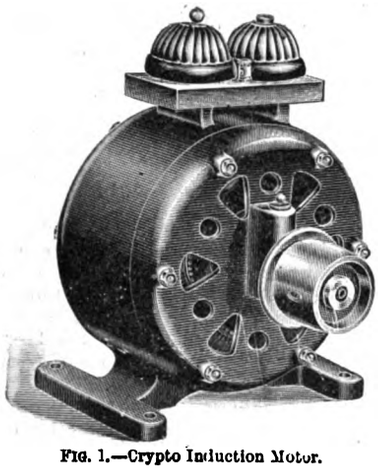


FIG. 1.—Crypto Induction Motor.

accomplished by simply closing the switch and pressing the button mounted on the top of the machine, the usual starting switch and resistance being dispensed with. Fig. 2 illustrates a "Crypto" motor-generator set designed to meet the requirements of those who, although supplied from alternating-current mains, wish to have a supply of continuous current for charging

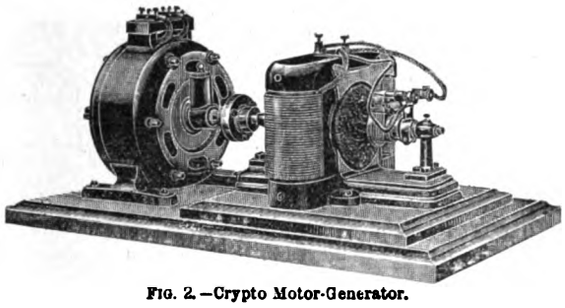

FIG. 2.—Crypto Motor-Generator.

accumulators, etc. For further particulars of these useful specialities we must refer the reader to a new list just issued by the Crypto Electrical Company, 3, Tyer's-gateway, Bermondsey-street, London, S.E.

Catalogues, etc., Received.

CROMPTON MOTORS.—In their new catalogue of continuous-current motors, Messrs. Crompton and Co., Limited, have, they inform us, endeavoured to give as much information as possible regarding the machines offered. They have fully standardised these motors, and are manufacturing them in very large quantities. Driving conditions, however, vary so largely that they often introduce considerable modifications in the mechanical parts. In the past English makers have been in the habit of carrying out these alterations either free or at a comparatively small extra charge. But this has been possible only by manufacturing the machines in small quantities, or by charging such a price for the standard machines that it will cover to a certain extent the cost of these alterations. Foreign competitors have adhered more rigidly to their standard designs, and refused definitely to make any modifications. Messrs. Crompton and Co. have endeavoured in their new list to take a middle course. They have reduced the prices of their standard motors to the very lowest figure, and if a customer requires some special modification introduced, they are prepared to make the same, in this case charging him with the full cost. The above is the system on which Messrs. Crompton and Co. have prepared their list. They have taken a plain motor as their basis, and have quoted separately for each variety of driving gear, from the ordinary belt to a geared motor. In geared motors, we notice, they have standardised three different speed ratios for each machine. The questions of "variable speed," "totally enclosed," and "reversible crane motors" are dealt with briefly in the list under notice, while the over-all dimensions, net and gross weights, and shipping measurements of the motors, particulars of the firm's standard pulleys, flywheels, couplings, foundation bolts, etc., are given. Some space is also devoted to starters, about which a considerable amount of information is given in a very handy form. To facilitate reference, the starters have been divided into three different types, each type representing a different rating in the resistance—viz., light-load starters, half-load starters, and full-load starters. These starters are listed with no-volt and overload releases, separate quotations being made for the various extras required for each type. The system here outlined, which has been adopted by Messrs. Crompton and Co., and so carefully elaborated by them, should commend itself to their customers.

ARC LAMPS.—From the British Thomson-Houston Company, Limited, Rugby, we have a copy of their pamphlet No. 176, describing the three forms of continuous-current series-multiple arc lamps which they manufacture. The first, with entirely self-contained line and substitutional resistances inside the lamp; the second, with self-contained substitutional and external line resistances; the third, with a self-contained line resistance only. The first and second forms are adapted to operate two in series on 200-250-volt circuits, and five in series on 500-600 volt circuits. The third form is suitable for operation two in series on 200-250-volt circuits only. It should be mentioned that this publication supersedes the firm's pamphlet No. 156 in part. An index to British Thomson-Houston current literature is also to hand.

DYNAMOS AND MOTORS, ETC.—The Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C., have recently issued a new list of their dynamos and motors for continuous current. This list is in three sections. The first (Section A) fully describes the special features of the machines, which are of a type designed to meet the growing demand for dynamos and motors of light weight, occupying small space, and possessing a large overload capacity, the brushes being fixed independently of the load. Section B is made up of tabulated data—mainly electrical—relating to the different standard sizes, which, it may be mentioned, cover a wide range, while Section C is comprised of line drawings and tables of dimensions. From the same firm we have three leaflets giving particulars of continuous-current and three-phase small motors for special purposes, such as driving dentists' machinery, massage apparatus, polishing discs, emery wheels, sewing machines, etc. We have also a reference list of dynamos and motors supplied by the Electrical Company, Limited and a leaflet illustrating their contact clock, which can be used in combination with any type or make of direct or alternate current watt-hour meter to form a two-rate or double-tariff system.

MOTOR STARTERS.—Messrs. Johnson and Phillips have recently issued a separate list of their motor starters dealing with standard sizes, from ¼ h.p. to 50 h.p. The design of these starters combines several special features. For instance, although fitted with the usual no-voltage and overload coils these starters have a special mechanism whereby they cannot be operated against an overload.

THE SCHULER MOTOR.—Some interesting particulars of the Schuler motor are contained in List No. 27, recently issued by the Lahmeyer Electrical Company, Limited, Bank-buildings, 109-111, New Oxford-street, London, W.C. It is pointed out that this motor is especially suitable for lift and crane work on single-phase circuits, due to its very large starting torque.

WESTINGHOUSE MOTORS.—The British Westinghouse Electric and Manufacturing Company, Limited, have lately published a revised circular dealing with their type "S.B." direct-current motors, ranging in size from ¾ h.p. to 100 h.p. The special features of these machines are fully described and illustrated, while the circular also includes many pages of tabulated data.

New Books Received.—"Einleitung in die Theorelische Elektrizitätslehre," by Dr. Ignaz Wallentin, K. K. Regierungsrath and inspector of State schools at Vienna. Illustrated with 81 diagrams. B. G. Teubner, Leipzig. 12s. This is vol. XV. of Teubner's collection of text-books for mathematical science and its application "Elements of the Mathematical Theory of Electricity and Magnetism," by J. J. Thomson, M.A., D.Sc., LL.D., Ph.D., F.R.S. Cambridge University Press. The most important of the alterations made in this third edition consists of a new chapter on the properties of moving electrified bodies. The author says many of these properties may be found in a simple way, and the important part played by moving charges in modern physics seems to warrant a discussion of their properties in even an elementary treatise.

CHELTENHAM ELECTRICAL UNDERTAKING.

The following is the full text of the report presented by Mr. James Swinburne (of the firm of Swinburne, Cooper, and Baillie) to the Corporation of Cheltenham. It is dated Oct. 22, 1904, and was considered by the Council last week.

Introduction.

Gentlemen,—The position is that in 1893 the Council decided to put down a central station for supplying Cheltenham with electric light and power. This has been carried out, and has resulted in an excess of expenditure over revenue, which is a disappointment to many, and I have been instructed to investigate the working of the electrical undertaking, and to report both as to its business and engineering management. Such cases as Cheltenham are by no means uncommon, and a great many local authorities are finding out that electrical generation and distribution are not necessarily as profitable as originally expected, owing to the difficulty in exactly appreciating the conditions necessary for success.

The town of Cheltenham is peculiar in many ways. It is essentially residential, and is spread over a large area in proportion to its population. The private houses of the most well-to-do residents are generally in their own grounds, so that the customers otherwise most profitable are spread over a large area. It is not a manufacturing town to any important extent, so there is but little sale of energy to private consumers for power purposes. The public street-lighting is carried out with arc lamps in a more elaborate way than usual, and many of the important streets are especially difficult to light well, owing to the foliage. The electrical tramways are worked by a private company supplied with energy in bulk from the Council's works. Cheltenham depends largely on its reputation as a health resort and as an attractive residentia l town; and in such cases it is usual for local authorities to sink money in public works which, though in the first instance coming on the rates, attract more visitors and residents, so that, the total rate being spread over a larger number, the rate of each individual is reduced rather than increased by an expenditure which has no direct return. Public works which make a town more attractive also increase the incomes of business and professional men, and the increase of rates in such cases may be more than covered by increase of income. A large proportion of the residents of Cheltenham, however, are not dependent on local prosperity. They have independent incomes, generally fixed, and are interested in keeping the rates down. Unless, therefore, non-paying public works increase the town so that their own rates actually decrease, they get no benefit from them in that way.

In making this investigation I have had every assistance and the frankest information from the officers of the Corporation, and I am especially indebted to Mr. Kilgour for the great trouble he has taken in giving me quantities of detailed information, and to Mr. Seacome. I have also been greatly assisted by the speakers at the representation on the 13th, especially Messrs. Ansell and Ley-Wood, and Major-General Babbage. A great many points they brought forward are not specially dealt with in the report, either because they did not prove to be valid criticism, or because they do not involve any important financial results, or else because they are involved in matters treated in full. I prefer to deal broadly with the whole question, and not to go into more detail than necessary to give a clear idea of my view of the position.

Accounts.

As the determination of profits depends very largely on the accounts, and as a great deal of what I have to say turns on what is a fair allowance for depreciation and antiquation, I will deal with the accounts first. The statutory method of keeping the accounts of a municipal electric undertaking is not adapted to the purpose, as it was apparently conceived without any idea of municipal trading. If a sewage works is put down a loan is raised, and the theory apparently is that the costs of working are made up out of the rates, and enough is also raised annually to pay off the loan in a certain period. This would be simplicity itself if the sewage works lasted exactly the term of the loan, and no longer. If at the end of the term it is as good as ever, and fit for another 25 years' work, it is clear that capital has been accumulated out of the rates. On the other hand, if it had to be superseded in 10 years, there is a loan left and no plant, and the question is complicated, more especially as the plant is not really the security for the loan. Whether municipal trading is good or bad is not to the point; municipal trading is fully recognised by Parliament, and electric lighting and tramways are recognised municipal trading, having come into the scope of local authorities because they involve interference with the streets. The accounts should therefore be suitable for a trading department; but they are not. An electric department might be comparable with a company in which the ratepayers are the shareholders and the council are the elected directors. If we follow this out, we have a company which is not allowed to have any subscribed capital. When capital is needed it issues debentures redeemable gradually over many years, and such debentures are not allowed except for buying plant. The plant is not security for the loan, but if it wears out before the loan is repaid, the company will be forbidden to issue any more debentures for new plant to replace it. The real security is the liability of the shareholders, or ratepayers. They hold no stock, but they take any profits, and find any losses. Their liability is unlimited as long as they stay, but it ceases if they go away. But they then generally become compulsory shareholders in other undertakings. No working capital is permitted. An industrial concern provides capital for running at a loss during the first few years; but in our analogous municipal company the shareholders pay rates or negative dividends to make up the trading losses.

Under such circumstances it is difficult to get out satisfactory accounts. The mere matter of dealing with debentures instead of capital would in itself give little trouble, but a great difficulty arises in estimating depreciation apart from sinking fund, and as the repayment and depreciation are the most serious items, there is a great uncertainty as to the real state of a concern. For instance, if money is borrowed for 20 years and an electric lighting station put up, and that installation just lasts 20 years without any repairs and then becomes valueless when the loan is paid off, there would have been an exact balance; but if the installation is as good as ever it is clear it must have been paid for out of profits, for as there is an installation to the good, and no loan against it, and no capital account, it must have come out of the revenue account. But suppose the installation needs repairs from time to time, small at first, and greater towards the end, so that it is as good as ever at the end of 20 years. Again we have a station to the good, and as there is no capital and no loan it must have come out of revenue. But suppose, on the other hand, in spite of frequent repairs, it becomes useless in 10 years, then we have a loan running, and no installation, so too little has been taken out of revenue. A private commercial concern would estimate how much it would cost on the average to keep the station in thorough order, or to build up a plant to replace the capital when the station had to be rebuilt. This would be the depreciation. The private undertaking will allow interest on the capital invested, and depreciation, including maintenance, to keep the machinery up to the full value of the capital. If the municipality charges the same interest and depreciation as the private concern, it has at the end of 20 years paid interest and depreciation, but has, in addition, paid off the loan or capital, so that it has taken too much out of revenue to the extent of the repayment. We thus find that depreciation should be charged in the municipal case, but, other things being equal, it should be less than the private concern's depreciation by the amount of the repayment. This is not a recognised principle; it is a personal opinion. The whole subject is much debated by leading authorities, and I have had to come to a decision to act upon here, so I give my reasons.

But in practice the case is much more complicated. Suppose, say, £10,000 is borrowed, and, say, a steam set put down, and the loan to be paid off in 20 years. Suppose ample maintenance allowed, so that the plant is in perfect order at the end of 10 years. It is then proposed to extend by borrowing another £10,000. Suppose the old plant is in perfect order—as good as when new, in fact—but the new plant to be put in is so much more efficient that it will pay better to scrap the old plant and put in two new sets. If application is made to the Local Government Board to borrow £20,000 and replace one set, they will refuse on the ground that that leaves a loan without its corresponding plant, and will cut the loan down to £15,000—that is to say, a deduction is made for the outstanding portion of the first loan. The result is that it is impossible to replace any machinery that becomes obsolete before its loan is repaid, except by improper methods, such as borrowing money for a total of three sets, and then discovering, after the money is obtained, that two will do the work if they are both new. This obliges local authorities to be irregular as regards loans, and this one element makes great confusion. Thus in the case taken, putting down the second £10,000 plant may be clearly a good investment; but replacing the first by a new and more economical plant is a different question altogether. The whole profits of the second set are to the good, but in the first set the investment of the £10,000 to replace it is only good if the difference of profit from the old and new sets will repay the investment of £10,000. The obvious way of keeping the matter straight would be to pay off the first loan. Thus, supposing there is £5,000 of the loan still owing, and the set is worth £2,000 as scrap, £13,000 is borrowed and the old loan paid off. In putting in the new set the council then considers whether it will pay at £10,000, but the replacing set must pay on £13,000 or it should not be put in. But this is not done, so the capital accounts become a tangle of loans, redeemable at different dates, borrowed at different times, at all sorts of rates of interest, and having no traceable relation to the plant actually in existence. The only way I can treat this is to regard the total loans as the capital of the concern, and to deduct the repayments from what would fairly be allowed as depreciation in a commercial under-

Digitized by Google

taking. It is a serious question, however, what rate of depreciation should be charged on plant that does not exist. In the hypothetical case of the £10,000 set, assume the £10,000 is borrowed, and the first set sold for £2,000 while there is still £5,000 owed on it, when is the £3,000 to be paid off? It may be wiped out in a year or two, or spread over the remaining term of the loan. The latter is the most convenient course, but it makes the accounts look better than they are in the meantime. On the other hand, depreciation is not chargeable on £30,000 when the two sets are running, and the old one gone, as there is only £20,000 of plant depreciating, but the repayment must be calculated on £30,000. At Cheltenham plant has been discarded; the result is that the sinking fund is partly to pay off loans whose corresponding plant is not there. The real state is thus worse than the accounts alone can show, but only to a small extent. In the question of depreciation and antiquation even commercial electric supply concerns are rather apt to underestimate the necessary allowance.

I would suggest as to the accounts: (1) That the interest and sinking fund should be charged as usual. (2) That a depreciation and antiquation fund on the present value of the plant, etc., be charged at a percentage rate that would be charged in private concerns, less the percentage rate for the sinking fund. Repairs and other maintenance charges to come out of this fund. (3) That a rent should be charged for the works, such as the Council would have obtained had they let the ground. (4) Properly speaking, the works should be charged with the same rates as they would have paid had they been a private concern, as the town would have received these rates had the concern been a company. This is advisable for the sake of accurate knowledge.

The Station.

In dealing with the matter before me, the first question is whether the Council was originally well advised in starting the electric light works in Cheltenham. Ten years ago it was the accepted opinion among engineering and financial authorities that electric lighting would pay well in such a town as Cheltenham. The Council, as a safeguard, took the opinion of authorities of highest repute in the profession. Their reports must be read in close connection with the particular scheme that was before them at the time, and not as dealing with the undertaking as now developed. Under the circumstances the Council were perfectly justified in going into electric lighting—in fact, they might have been open to censure if they had not.

The next question is whether alternating or direct current should have been employed, and where the station should have been. The station was put where it is to be near the destructor, which was expected to supply steam for some 70 h.p. At that time the idea of getting steam from destructors was very prevalent, but though in some towns the destructor helps, this depends on the type of destructor and on the type of town refuse. This varies from place to place. Cheltenham being a scattered town, the road refuse may be large in proportion to the combustible house refuse. In my opinion it would have been an error to put the station where it is for the sake of the destructor alone, especially as the steam pressure was 80lb. on the square inch. It is, however, an advantage, especially important in a place like Cheltenham, to put the station out of the way, as there is sentimental objection to its being in the middle of the town. But this means cost of high-pressure mains, and sub-station transformers. The long high-tension mains mean money in capital, for themselves, for the transformers, and for the buildings, and cost in revenue also. It would, I consider, have been better to have had the station more central, distributing by low-pressure alternating currents in its neighbourhood and by transformers in the distant portions, or, as is more usual, by direct currents on the three-wire system, at any rate, for the important and central districts. Ten years ago, however, the system that has been adopted was the fashion, and it was very natural that it should have been selected for Cheltenham. I do not consider that the question of the position of the station is vital; it would have made some but not a great deal of difference.

Distribution.

I find the main cause of the present position of the undertaking is that it has been managed too much with a view to a rosy future than a matter-of-fact present. As an instance, the supply of energy was commenced about May, 1895, from works costing £16,880, but in July of the same year it was decided to apply for a loan of £10,000 for extension; then again in February of the following year it was resolved to apply for a further loan of £15,000 because of the delay in obtaining the sanction of the Local Government Board. It would have been more prudent to have accepted the view expressed in Mr. Hall's report until there were distinct indications that the undertaking would pay. I may mention this instance as an illustration of what I conceive to have been the general policy. If the mains are laid over a scattered area to meet the demand of a few consumers, it is clear that a little extra cost will make them large enough to meet a large number of consumers. For instance, when the first consumer in a street comes on, a main may be laid that will just supply him, but it is better to put down a larger main that will supply something like the expected future demand along it. The cost of the mains themselves is but little more, and the laying is the same. Adding more main capacity afterwards costs as much as the original mains unless an expensive draw-in system is used. The same reasoning applies to transformer sub-stations. A sub-station put down for a small local supply may soon be too small, and if the supply grows, a new sub-station will cost a great deal more than the extra expense of making the original sub-station large enough. It is, therefore, sound business to put down distributing mains and accessories capable of coping with a much larger demand than is guaranteed or expected immediately. But, though it may be impossible to go slowly in each street, it is not impossible to go cautiously in a whole town. The sound method would have been to carry out the intention of Mr. Hall's report and to have secured the greatest number of consumers with the smallest capital expenditure. This could have been done by wiring that portion of the town where the demand was likely to be the most dense. It could then have been nursed up until the consumption was heavy in proportion to the mains. The most promising streets in the optional area could have been cabled afterwards, and so on. This may sound slow, but it is safer. Instead of this, mains have been extended in a way which points to a complete absence of consideration of their really probable revenue. When a main is put down which cannot be remunerative for some years, it must be remembered that the depreciation and interest are going on in the meantime, so that a distant revenue must be much larger to pay for immediate capital investment. In many of the streets and roads it will be long before the revenue will be sufficient. I may mention as examples of such mains, the high-tension cables along the Evesham-road—part of this is outside the municipal boundary; the high and low tension mains along Hale's-road, Battledown-approach, and Birchley-road; the high-tension main along Oakley-road; the low-tension main and transformer station in Hewlett-road; the high-tension main along Alstone-lane; the high and low tension mains along Queen's-road; the high and low tension mains along Lansdown-road and Gloucester-road; the high and low tension mains in Park-drive. I mention these to show the type of main that is generally unprofitable.

The consumers in Cheltenham are particularly difficult to supply economically, as so many of the houses are villas in their own grounds, scattered sparsely along broad roads. The length of the mains and services are thus excessive. The Council is not compelled to provide light anywhere outside the compulsory area, and need not do so unless it will pay. As a safeguard against unreasonable refusal on the part of the Council, the order authorising the lighting provides that customers can demand supply on specified terms which practically ensure safety to the Council but are rather prohibitive to the consumer. In practice it is usual for the lighting people to make special terms by which the outlying consumer pays a fair contribution towards the service, or guarantees a minimum revenue, or both. It must be borne in mind that the consumers who insist on light in a sparse district are expected to guarantee enough revenue to go towards repayment of mains; it is not only a question of services. That many consumers are willing to take the light on such terms is shown by their doing so during the last year, but before that time expensive outlying consumers appear to have obtained the light on the same terms as those in the compulsory area. This must have been a source of loss to the undertaking. The result is that the system of mains in Cheltenham is a sort of skeleton, with very little on it. All that is wanted is flesh on the bones. This growth must be a matter of time, and I have no doubt the revenue will increase in the near future without corresponding increase of capital expenditure, as the mains are there; but many of the mains will always remain a very doubtful investment. In my opinion, the extension of the mains has been too rapid, and somewhat reckless. This puts the undertaking at a great disadvantage during its early life, and though it has its advantages later, when more lights can be taken on at small extra capital cost, the policy has been carried to extremes.

Public Lighting.

In dealing with this it must be remembered the Council is both buyer and seller; it is simpler to consider the electric works as a separate concern. We have therefore to consider whether the light is what the town wants, and whether it pays a fair price for it, from the town's point of view, and whether the lighting is the best the works could do from the point of view of internal economy for a given amount of light, and whether the price paid the works is right from the works' point of view. The public lighting by arcs in Cheltenham has increased from 37 lamps in 1898 to 388 now in use. The capital allocated to public lighting appears to be £47,771, making the expenditure on each lamp about £123. The interest and sinking fund on your loans comes out about 7 per cent. per annum, so that the annual cost per lamp under this head is about £8. 12s.

Digitized by Google

These figures allow nothing for depreciation and antiquation beyond the repayment, and in my opinion a further 2½ per cent. should be allowed to cover the difference between the depreciation and the repayment. This makes the depreciation and antiquation 9½ per cent., not 10. The cost of energy, however, includes an item for maintenance and repairs, which must be considered as depreciation. Taking this as equal to ½ per cent. on the capital, brings the depreciation and antiquation up to 10 per cent. total. These items together amount to over £11. 13s. per lamp per annum. The total energy generated in 1904 for public lighting was doubtless nearly 700,000 units, or, say, 1,770 Board of Trade units per lamp. The net cost of producing energy for public lighting depends on several unknown factors, and can only be estimated. By taking the cost excluding capital charges to be 1d. per unit, the annual cost of energy per lamp will be about £7. 8s. The cost of carbons and attendance during the year 1903 and 1904 was £1,221, or, say, £3. 3s. per lamp. On this basis the gross cost of each lamp would be £22. 4s., and the total cost would be £8,610 per annum. It is a question of policy as to whether a few streets should be lighted on so liberal a scale, but it appears to me that a town of 50,000 inhabitants can hardly afford to spend the sum of £6,698 allocated to public lighting in the accounts of 1903 and 4, to say nothing of the larger sum of £8,610 necessary to make the undertaking pay expenses, and therefore really borne directly and indirectly by the town. From the works point of view the arc system has been well installed. The system of lighting by special mains with transformers was about the best practice at the date, and from an engineering point of view the arc lighting is carried out satisfactorily.

Tramway Supply.

Evidently if the works asked too much from the tramway, the tramway would either not start at all or it would generate its own power. The cost of generating its own power is, therefore, the upper limit of the price to be asked. The lower limit is the lowest price at which it will pay the works. In estimating what price will pay the works the tramway price should take no account of the capital in town mains, or in anything but the part of the station that works it, and the mains from it. The price charged is, in my opinion, low. It might be raised without approaching too nearly the cost of generating by the tramway people themselves. If the tramways company generated their own power, it is probable that they would have to sink about £14,000 for the generating station and site. The sum to be set aside annually for the payment of interest and depreciation would depend in a measure on the prosperity of the company, but might be put at 12 per cent. per annum. I have taken 12 per cent. instead of 10 per cent. because an investor in a private company, having no security, expects higher interest. A local authority borrows at a low rate, because the security of the rates is behind it. I do not mean that a local authority is at an advantage because it can borrow money at a lower rate. That is not so, because the ratepayers are saddled with the risk as well as the interest. All the same, the extra 2 per cent. should come in in this way in the estimate. The annual charge on this basis would be £1,680. The tramways use about 250,000 Board of Trade units per annum, and the net cost at which they could generate themselves would under the circumstances probably be not less than 1¼d. per unit, excluding capital charges and maintenance. The total cost of energy on this basis would be, say, £3,000 per annum, or 2·88 per unit. The sum obtained from the tramways company in the year 1903 and 1904 was £1,786, or 1·7, leaving a margin of 1·18. The amount of capital allocated to traction by the Corporation is about £12,000, and taking interest, repayment, depreciation, and antiquation on a basis of 10 per cent. per annum, as little or nothing can have been paid for maintenance or repairs yet, the capital charge should be £1,200. The price of energy, making allowance for load factor, and including a proper proportion of management charges, would seem to me to be about 1d. per unit exclusive of capital charges. The total cost must, therefore, be about 2·15 per unit. To permit a profit, I think the tramways company might reasonably be charged a flat rate of 2½d. per unit instead of 1·7d. now charged. I must point out that municipalities often supply themselves, or even private companies, at 1½d. per unit—in fact, 1½d. has somehow come to be regarded as the right price. I have, therefore, given my reasons fully for holding that the price should be so much higher.

The Engineering of the Undertaking.

Apart from the questions of policy in the rapid extension of mains and the installation of sub-stations to deal with a much larger future consumption, and of policy in putting down so many arcs, the engineering has, in my opinion, been carried out well and without extravagance. The station is designed on economical principles, without the somewhat usual extravagance in building design. The total capacity of plant installed at one time and another appears to have been 2,166 kw. Of this a certain quantity of plant has been discarded for adequate reasons. This is not a material point, except that it emphasises my view that a sum should be provided out of revenue for depreciation and antiquation in addition to maintenance and repayment. It is not possible to find out whether the cost of generation is low without making tests of the plant and putting the Council to further expense, which is unadvisable. Comparisons with other undertakings are very misleading because the conditions vary widely. Cheltenham ought to be low, because the tramway and the large public lighting load improve the load factor; but this, on the other hand, suffers from the character of the private lighting, which is largely shops. What is wanted is more private house supply. The main difficulty arises from the heavy load of the capital sunk, which weighs upon the undertaking. This cannot be reduced, and though reducing the working cost to the lowest possible limit is of great importance, the chief thing is to increase the sales so as to spread out the load of capital.

The Future.

The reference does not specifically ask me to make suggestions as to improvements beyond what are implied in the report, but it may be as well to do what I can. The main crux of the position is that the undertaking is heavily handicapped with excessive capital spent on the one hand; while the revenue which would justify the expenditure has not yet come into existence. The capital sunk in the distribution system is largely premature. What is wanted is to render it useful by getting more customers. I suggest that a system of energetic house-to-house canvassing for customers be put in hand. Customers will be especially shy just now, as through the discussions about the lighting they may have got a wholly wrong idea that the supply is in itself bad or doubtful, and they had better not take it. The great aim should be to obtain customers in the streets which already have mains, so as to increase the revenue without a corresponding increase in the capital. Private house consumers are specially wanted; and the canvasser should point out that the best way of reducing the rates is to take the light. A good deal of the town proper has no mains. Even though the unwired districts may not be opulent, they may pay very well if the consumers are close together. New streets into which mains can easily be led should, therefore, be canvassed, but the mains should not be put down until there is ample promise of immediate support.

Many customers are afraid of maximum demand systems of charging; they do not understand them, and think there is something unfair, whereas they really favour the consumer. It may, therefore, be advisable to give the option of a flat rate—that is, payment by energy used, apart from rate at which it is used, or payment corresponding to that for gas. Prepayment meters also bring in considerable revenues in the less flourishing districts of many towns, and are worthy of consideration. On the Continent the "Abonnement," or payment per lamp per annum, system is much liked by consumers, and it might be considered in Cheltenham. Free wiring would no doubt increase the consumption; but it involves further capital outlay if undertaken by the Council. I do not think it would be sound policy to raise the price for private supply. It would tend to discourage consumers. It may be better to encourage them to come on and take advantage of the low rates, increasing the revenue, especially if more of the existing plant is made available by a change in the public lighting.

The capital sunk in the arcs for street-lighting is sunk, and cannot be recovered; the only question is how to reduce the current expenses. I consider in a great many of the streets the public would be well enough satisfied with much less light. I would recommend that Nernst lamps be put into the arc standards, beginning in the less public streets, to feel the way. This would reduce the light, of course, but not so much as to lead to complaint, and it would reduce the cost of power very seriously, depending on the size of lamp used. The Nernst lamps would go into the present standards. The capital cost involved is small, and might be almost met by the sale of the arc lamps. There are other solutions, such as small arcs, especially enclosed arcs, but I mention the Nernst, as I know it well, for I have been connected with the introduction, and it seems the best solution. By reducing the power it allows the plant at the works to be available for taking on more private lighting, and less of the station is then allocated to the arcs, so that the capital charge is also reduced, but not in anything like the same proportion. This change would not show in the electric so much as in the general accounts. It would result in a large saving to the ratepayers in the item of street-lighting, but as the electric department sunk capital in arcs before the Nernst existed, the town should still pay for this capital sunk. The real saving would be that the town would pay less for energy, and the station would have more plant available, and would sell this energy to private consumers without further capital outlay. The price of the power for traction should be raised to something like 2½d.

The question of how the deficit should now be dealt with is hardly in my province as an engineer. I certainly consider it ought to have been charged to the rates each year. 7 (1) (c) of the Electric Lighting (Clauses) Act, 1899, runs: "Any deficiency

Digitized by Google

of income in any year when not answered out of the reserve fund shall be charged upon and payable out of the local rate." Whether it should now be liquidated by charging it to the rates, or by a loan, makes no difference in the sense that the ratepayers must pay it in either case in the long run. The deficit has been caused by the present ratepayers through their elected representatives, and it is hard to make the next generation of ratepayers bear the burden.

In conclusion, I would strongly urge the Council to keep the most jealous watch on their capital expenditure. Unless a proposed expenditure shows an immediate revenue such that the profit on the revenue amounts to at least 10 per cent. on capital expenditure the investment is unsound. If the revenue is prospective only, and may only come in some years' time, the capital should be taken as increased at compound interest for the idle years. Neglect of this precaution is very common, and leads to many financial disasters. The Council is alone really responsible for expenditure of capital, and should themselves clearly see the probable profits estimated in money of every expenditure of capital. (Signed) JAMES SWINBURNE.

LEGAL INTELLIGENCE.

RIGHT OF WAY.

In the Chancery Division on Tuesday the action of Ord and Maddison, Limited *v.* the Corporation of Darlington and the Right Hon. John Lloyd Wharton came before Mr. Justice Buckley.

Mr. Buckmaster, K.C., and Mr. Boothwick appeared for the plaintiffs; Mr. Astbury, K.C., and Mr. Gates for the Darlington Corporation; Mr. Danckwerts, K.C., and Mr. Dunham for Mr. Wharton.

The plaintiffs claimed as assignees of John Robt. Ord and Wm. Henry Forster Maddison, and in their own right, an injunction restraining the defendants, their servants, or agents, from excavating, building upon, or enclosing the site known as Freeman-street, Darlington, or from otherwise obstructing or interfering with the plaintiffs' right of way over the street. They also asked that the defendants be ordered to remove the obstruction and restore the surface of the street to its original level, and claimed damages for obstructing and interfering with the plaintiffs' right of way, and for breach of a covenant implied or expressed in a conveyance from Mr. Wharton to them.

The plaintiffs alleged that the obstruction of the part of Freeman-street by the Corporation caused serious damage to them, and if it was allowed to continue the width of the street would be reduced from 40ft. to 28ft., and plaintiffs would not only be deprived of their right of way, but would be precluded from utilising their land adjoining the street for building upon it dwelling-houses of two storeys in height fronting on the street, and their land would thereby be a great deal reduced in value.

The defence denied the rights of the plaintiffs under the conveyances, and said that about April, 1903, the Corporation, in pursuance of statutory powers, commenced to erect on the land buildings for the purpose of the electric tramways used in their tramcar system for the borough of Darlington. The buildings in question were of great public importance to the proper conduct of the borough system of light railways, which were of great benefit to thousands of working-men and others. The piece of land as to which plaintiffs complained was essential to the use of the buildings, and if the Corporation were compelled to remove the buildings they would suffer great pecuniary loss and inflict discomfort and inconvenience on the public. The buildings had been erected at a cost of £8,000.

TRAMCAR OBSTRUCTION.

In the Aberdeen Police Court, on Tuesday, George Henderson Duncan, cab driver, was charged with having wilfully obstructed an electric car by driving a horse and cab slowly in the way of the car. He was further charged with assaulting the motorman.

Alexander Urquhart, motorman, stated that he was driving a car westwards along Union-street, and when near Market-street he made up on a cab driven by accused. Accused drove straight on to the rails in front of the car, and continued to drive up the street slowly on the rails. Witness rang his gong, but accused paid no heed. There was no traffic to prevent the cab from proceeding along the street without going on the rails. The car was delayed two or three minutes. Accused left the car rails and passed three carts before Belmont-street was reached, and then returned to the rails. At this time a collision was narrowly averted. Accused then drove off the rails, and the car passed the cab. At Belmont-street witness left the car with the object of ascertaining the number of the cab. He asked accused to stop, but accused whipped the horse and continued. Witness then took hold of the horse's head to stop the cab, and accused struck him on the face with the whip.

A **Passenger** gave evidence to the effect that the ringing of the gong going up Union-street attracted his attention. He looked out, and saw a cab being driven slowly in front of the car. There was no traffic, so far as he could see, that would have prevented the cab being driven on the side of the street.

Rev. John Meany stated that he was a passenger inside the car. He noticed as the car left Market-street that a cab was on the lines in front of the car. The motorman rang his gong violently, and continued ringing it all the way to Belmont-street. Near Belmont-street there was almost a collision, as the cabdriver had driven off the rails and then returned to the rails. Witness thought credit was due to the motorman for having so smartly averted a collision. He saw no obstruction to prevent the cab from proceeding without running on the rails.

Several other passengers gave corroborative evidence.

Mr. Alexander Duncan, father of the accused, stated that he was on the box of the cab with his son at the time of the alleged offence. He considered it was impossible to get off the rails, as there were a number of carts passing.

Accused stated that he had no idea of obstructing the car whatever. He was in a hurry at the time, and was driving at a rate of about six miles an hour. He denied having struck the driver of the car with his whip.

The **Magistrate** stated there was no doubt from the evidence that accused had obstructed the car, and he thought credit was due to the motorman for having averted what might have been a serious accident. He did not think, however, that the charge of assault had been proved, and he found accused not guilty of that charge. Accused would have to pay a fine of 10s., the alternative being five days' imprisonment.

Arthur Farnfield was summoned before Mr. Lane, K.C., for obstructing an electric tramcar in Goldhawk-road, Shepherd's Bush. The evidence showed that the defendant deliberately put his cart broadside against the car on the lines and refused to move. When requested by a point boy to move he used bad language, and struck him across the face with his whip.—The magistrate imposed a fine of 78s., with 2s. costs.

William Bell, giving an address at Wood Green, was summoned for obstructing an electric car in Chiswick High-road. He was said to have driven a large van deliberately at a very slow pace in front of the car for three-quarters of a mile, causing the car to be delayed for 15 minutes.—He was fined 13s., with 2s. costs.

TRAMCAR COLLISION.

Plaintiffs, the British Electric Traction Company, the lessees of the Croydon tramways, claimed £4. 2s. from Messrs. Grant Bros., High-street, Croydon, for damage to two tramcars, which they alleged was due to the negligence of defendants' driver. There was also a counter-claim.

Mr. Newnham, for the plaintiffs, said the accident out of which the action arose occurred in the main Brighton road. Defendants' two-wheel covered cart came out of Bartlett-street into Brighton-road as two tramcars were approaching from opposite directions. Between the down tramcar and the pavement was a cart, the driver of which, unfortunately, was now dead, and the defendants' cart, instead of turning down on its near side, as, he submitted, it ought to have done, dashed out into the car which was coming towards Croydon, and was thrown back on to the down car. Both cars were considerably damaged.

Corroborative evidence was given by the drivers of the two cars.

The driver of the cart said he came out of Bartlett-street at the rate of about three miles an hour. One car was then standing, and the other car came up, caught the step of his cart, and threw the cart against the other car. There was plenty of room for him to get through, and he heard no bell or other signal. The up car was 50 yards away when he started to come out of Bartlett-street, and it came that distance while he was going 20ft. If the motorman had slowed down he could have got clear of the car.

A witness said the cart came out of Bartlett-street at almost a walking pace. The car from Purley came up from behind and dashed into the cart.

Another witness said the car coming up the road ran into the cart because the driver of the car had not proper control over it.

Police-constable Bradford, who was 100 yards away at the time of the accident, said the cart came out of Bartlett-street at a slow trot.

A boy in the service of Messrs. Grant, who was in the cart, said that as they pulled out of Bartlett-street he could not see anything coming and he heard no bell rung.

Mr. Easton, for the defence, submitted that the evidence conclusively proved that defendants' driver was not guilty of any negligence whatever.

The **Judge** said he was quite satisfied that the defendants' driver was to blame for the accident. He had always understood it to be a principle in the decision of these cases that it was incumbent on drivers entering a main road from a side street to take a good look and slow up. The driver in this case came out before one tramcar and came into collision with another one. He was satisfied that the driver was trying to dash between the two cars. Judgment for the plaintiffs on the claim and counterclaim.

FARE QUESTION.

Mr. W. T. Williams, commercial traveller, was charged at the Nottingham Summons Court last week with refusing to pay the fare when travelling on the tramways.

On the Sherwood route of the city tramways the cars start from Station-street and travel to Shakespeare-street in the first 1d. stage. The second stage commences at Market-street and extends to Hucknall-road. The defendant boarded a car in Wheeler-gate and rode to Babbington-street. The conductor took the fare for the first stage before the car reached Market-street, and when he asked the defendant for a second penny to carry him over the second stage, he refused to pay.

Evidence was given by the conductor in support of the opening statement.

Digitized by Google

Defendant contended that a passenger who entered a car at any point in the Market-place was entitled to ride over a 1d. stage from the Market-place. In the present instance he submitted that he had a right to ride from Friar-lane to Babbington-street for 1d.

The Bench agreed that a technical offence had been committed, and ordered defendant to pay 2s. 6d. costs.

STREETS THROUGH FACTORIES.

Mr. J. H. Heathman, the ladder and fire-escape maker at Parsons Green, has been, we are informed, for nearly five years troubled by the London County Council respecting his works at Parsons Green. We gather that originally a piece of ground was bought for the purposes of his factory, and that this is now entirely covered by buildings. The land is freehold, but the London County Council wish to get a decision to the effect that there is a street through this area. The magistrate who heard the case has decided for Mr. Heathman with costs, but the London County Council have appealed, and further trouble and expense will have to be incurred. We await the decision with considerable interest.

COMPANIES' MEETINGS AND REPORTS

TYPEWRITING TELEGRAPH CORPORATION.

The fifth ordinary general meeting of the Typewriting Telegraph Corporation, Limited, was held on Monday at Winchester House, Mr. A. J. Parker presiding. There was a loss on the year of £2,434.

The **Chairman**, in moving the adoption of the report, which was accepted, stated that the directors had not sold any of the foreign patents, nor had they been successful in securing any really large orders. They had at last been successful in inducing the War Office authorities to see the instrument at work. The War Office had bought two sets, which were now being tested at Chatham, and the Company anticipated a favourable report, and might expect to receive orders. Referring to the negotiations with foreign governments, he said that Russia had some of the instruments at present in the Far East, and the directors believed they would secure a very considerable order from St. Petersburg. If this hope were realised they would have a good chance of clearing out the present stock. The prospects of success with the military world were distinctly good, and the present machine was not likely to be endangered. In the field of the Post Office the position was not quite so promising with the old instrument, but with the new standard teletyper they believed they would have the very best instrument. In regard to the financial position, they wanted time to realise the assets, exploit the new instrument, and carry on operations for a couple of years. If success did not come within that time, there would be nothing left but to liquidate.

An extraordinary general meeting followed, when the chairman's proposal that further capital to the extent of £3,000 should be raised by 10 per cent. debentures was adopted.

INDUSTRIAL STORAGE BATTERY SYNDICATE.

An extraordinary general meeting of the Industrial Storage Battery Syndicate, Limited, was held on Monday at Winchester House, Mr. C. Temperley presiding.

The object of the meeting was to confirm a resolution passed by the shareholders making an addition to the articles of association, thereby giving the Company power to subdivide its shares into shares of a smaller amount.

Mr. O. W. Powers seconded the resolution, which was carried unanimously.

Resolutions were then submitted authorising the directors to divide the shares not yet issued into two shares of 10s. each, and to reduce the capital of the Company from £100,000, divided into 81,007 shares of £1 each, and 37,986 shares of 10s. each, to £59,496, divided into 118,992 shares of 10s. each, and that such reduction be effected by cancelling capital which had been lost or unrepresented by available assets to the extent of 10s. per share upon each of the 81,007 shares issued.

The **Chairman** stated that the directors had considered several schemes for getting further capital, and the meeting had been called in order to pass such resolutions, and to see to what extent the shareholders would support the scheme.

A **Shareholder** asked whether any further progress had been made with the working of the patent?

The **Chairman** said the experiments had been very satisfactory, and several orders were on hand.

Mr. Powers seconded the resolutions, and impressed upon the shareholders the necessity of providing additional capital.

The resolutions were carried.

NEW COMPANIES REGISTERED.

Crawshay-Williams, Limited. — Capital, £6,000. Object: to carry on the business of motorcar, vehicle, and cycle manufacturers, electricians, engineers, suppliers of electricity, etc. Registered office: 98, Gresham-street, E.C.

Electric Power Development Company, Limited.—Capital, £25,000. Object: to carry on the business of suppliers of electrical power, proprietors of electric light, telephonic, telegraphic, and other works, generators, storers and transmitters of electricity for all purposes, mechanical and electrical engineers, manufacturers of rolling-stock, etc.

I. V. O. Kill-All Chemical Company, Limited. — Capital, £2,000. Objects: to acquire as a going concern the business of the I. V. O. Kill-All Chemical Company, now carried on at Burmantofts, Leeds, to carry on the business of manufacturing chemists and manufacturers of electrical, scientific, and other apparatus and materials, etc. Registered office: 2, Argyle-road, Burmantofts, Leeds.

Hastings and District Electric Tramways Company, Limited.—Capital, £500,000. Objects: to adopt agreements (1) with M. S. Myers and C. Mendel, (2) with the Hastings Tramways Company, and (3) with Dick, Kerr, and Co., Limited; to construct, purchase, lease, or otherwise acquire light or other railways and tramways in Hastings and Bexhill or elsewhere; to obtain any orders or Acts of Parliament in connection with the same; and to carry on the business of tramway and railway proprietors and workers, electricians, mechanical engineers, contractors for public and other works, etc.

Liens Registered.

Burnand Transformer Company, Limited, Manchester.—Lien registered Nov. 3, for £1,000 second debentures; no trustees; charged on all the property, present and future, including the uncalled capital for the time being, subject to debentures for £1,000.

Northampton Electric Light and Power Company, Limited.—Lien registered Nov. 7 for £400 4 per cent. debentures, part of a series not to exceed two-thirds of the subscribed and paid-up capital. Amount previously issued, £32,220. No trustees. Charged on the undertaking and all the property, present and future, including the uncalled capital for the time being.

South Staffordshire Tramways (Lessee) Company, Limited, Strand, W.C.—Trust deed registered Nov. 3 for £54,700 debenture stock, with power to issue further stock ranking *pari passu*, so that the total amount does not exceed £100,000. Trustee: Law Guarantee and Trust Society, Limited. Charged on leasehold interests in the South Staffordshire Tramways, plant, machinery, etc., certain shares of the company, and the undertaking and assets, present and future.

Underground Electric Tramways Company of London, Limited, London, E.C.—Trust deed and instrument of charge under the Land Transfer Acts, registered Nov. 9, for securing £850,000 debentures. Trustees and mortgagees: J. Trotter, 2, Princes-street, E.C.; H. Cookburn, 61, Threadneedle-street, E.C.; and J. A. Dawes, 9, Angel-court, E.C. Charged on the company's generating station, plant, and machinery at Lots-road, Chelsea, together with cables and ducts therefrom to Earl's Court, all rights and interests in certain contracts for the supply of electricity, etc., and all loose plant, machinery, and chattels in or upon the said station.

PERSONAL.

Prof. Henry Adams, M.I.C.E., has recently retired from the City of London College, where for 35 years he has been head of the engineering department. He is, however, still continuing his practice as a consulting engineer at 60, Queen Victoria-street, E.C., where he has had offices for the last 25 years.

The Horsham District Council have decided to increase the salary of Mr. Morgan, their electrical engineer, from £175 to £225 per annum. Since his appointment the output at the works has considerably increased, and with it the engineer's duties.

The Erith Town Council have appointed Mr. Grainge assistant electrical engineer at the electric light station.

On Tuesday last week Mr. E. G. Love, superintendent of mains and overhead tramway equipment, was presented by the staff and employés of the Halifax Corporation electricity works with a handsome marble clock, suitably inscribed, as a mark of esteem on his recent marriage. Mr. W. M. Rogerson, borough electrical engineer, made the presentation in the presence of a large gathering, representing all the departments of the works.

Mr. Robinson, assistant electrical engineer at Worksop, has resigned.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Porto Alegro (Brazil).—The term for receiving tenders for an electricity station, already announced, has been prolonged to Nov. 30.

Banza (Spain).—The Municipality require tenders for the electric lighting for five years. Particulars from the Alcalde, Banza (Jaen).

Pola de Siero.—The Municipality require tenders for the electric lighting for 10 years. Tenders by Nov. 30 to the Alcalde, Pola de Siero, Spain.

Madrid.—The General Telegraph Office require tenders for installation and working telephones in the town of Talavera. Tenders to above by Dec. 7.

Guirgia (Roumania).—Tenders are required for the electric lighting of the town. Particulars from the town's secretary. Tenders by Jan. 28, 1905.

Ibros.—The Municipality require tenders for the electric lighting of the town for 15 years. Tenders by Nov. 22 to the Alcalde, Ibros, Province of Jaen, Spain.

Salamanca.—The Municipality require tenders for public electric lighting of the town. Tenders by Dec. 12 to above or to Direccion-General de Administracion, Madrid.

Digitized by Google

Swansea.—The Corporation invite tenders for a 12 months' supply and delivery of motors and starting switches. Tenders by Dec. 1 to Mr. Jno. Thomas, town clerk. See advertisement.

Manchester.—The Tramways Committee invite tenders for the supply, delivery, and erection of one 15-ton and two 5-ton electric overhead travelling cranes. Tenders by Nov. 22. See advertisement.

Caen (France).—The Prefect requires tenders for concession of a tramway from Eyes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1, 1905.

Llandilo (Wales).—The Urban District Council invite tenders for testing and calibrating the electricity meters installed in the town (70 in number). Tenders to Mr. R. Shipley Lewis, clerk, Llandilo, before Dec. 6.

Newport (Mon.).—The Electricity and Tramways Committee invite tenders for various machine tools. Particulars may be obtained from the Borough Electrical Engineer, Town Hall, Newport, Mon. Tenders to the Town Clerk by first post on Nov. 21.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Johannesburg.—The Municipal Council invite tenders for two 35-ton electric overhead travelling cranes and transformer pillars and switchgear. Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W., and received by them not later than Dec. 27.

Rotherham.—The Corporation invite tenders for wiring the new isolation hospital buildings in Badsley Moor-lane. Specification and forms of tender at the office of the Borough Electrical Engineer, Rawmarsh-road. Tenders to be sent to Mr. W. J. Board, town clerk, Town Hall, Rotherham, by Nov. 21.

Glasgow.—The Governors of the Glasgow and West of Scotland Technical College invite tenders for a complete wiring installation and switchboards for the electric lighting of their new buildings. Specification may be obtained from Mr. H. F. Stockdale, secretary and director, 38, Bath-street, Glasgow, to whom tenders must be delivered by Nov. 26.

Brussels.—Tenders are invited for the construction of an electric generating station and other works in connection with the establishment of a goods station at Brussels. The estimated cost of the work is about £24,367. A deposit of about £280 is required to qualify any tender. Specifications (price 1s. 10d.) and further particulars may be obtained from M. De Rudder, Administrateur des Voies et Travaux, 11, Rue de Louvain, Brussels.

Perth (Australia).—Tenders are invited by the Duputy-Postmaster-General for the supply of the following telephone material; 19½ miles 26-pair lead-covered cable, dry core, to standard specification No. 7; 5,000 paper sleeves, 3in. long by ⅛in. diameter; 350 yards paper strips, 2in. wide. Conditions, etc., may be obtained at the General Post Offices at Perth, Adelaide, Melbourne, Sydney, Brisbane, and Hobart. Tenders by Dec. 28.

Shanghai.—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Peck and Co., 63, Leadenhall-street, London, E.C. Tenders by March 31.

Sydney.—Tenders will be received at the office of the Acting Deputy Postmaster-General, Sydney, New South Wales, up to 2.30 p.m. on Dec. 28, for the supply and delivery at the Departmental Stores, Sydney, of telegraph, telephone, and electric light material. Specifications and general conditions may be seen and tender forms obtained at the General Post Offices, Sydney, Melbourne, Brisbane, Adelaide, Hobart, and Perth. Samples may also be seen at Sydney, Melbourne, Brisbane, and Adelaide.

Bromsgrove (Worcs.).—The Visiting Committee invite tenders for the supply and erection at their new lunatic asylum of the following plant: (Section A) engines, dynamos, booster, and steam services; (B) storage battery and accessories; (C) main switchboard, ring main, feeders, distribution boards, wiring, lamps, and accessories. Specification, etc., may be obtained from Mr. Robert J. Oliver, clerk of the Visiting Committee, Shirehall, Worcester, on payment of £5 for each section of the work as above, which will be returned on receipt of a bona fide tender.

Belfast.—The Town Council invite tenders for the following tramway works, equivalent to about 70 miles of single track: (1) permanent way, road-bed, paving, and bonding; (2) overhead electrical equipment; (3) underground feeders, telephone and test wires, spare conduits, etc.; (4) steam dynamos, switchboard, also three-phase plant, condensing plant, overhead traveller, station lighting, etc.; (5) boilers, superheaters, mechanical stokers, economisers, coal and ash conveying plant, steam exhaust and feed pipes, pumps, etc.; (6) double-deck electric tramcars. Tenders must reach the Town Clerk's Office by 18th inst., at noon.

Leith.—The Corporation invite tenders for the supply of the following tramway cars, delivered free at Leith: Passenger cars—double-deck, single-truck cars with reversed staircases, equipped with motors, controllers, brakes, lifeguards, lights, etc., complete; number, 30. Alternative tender for the same car with ordinary staircase. Double-deck, single-truck cars with reversed staircases and covered top, equipped complete as above; number, 7. Alternative tender for same covered-top car with ordinary staircase. Sprinkler car—sprinkler car with water-tank, sprinklers, grooved watering pipes, revolving brooms, snow-plough, with motors and all other necessary electrical equipment and brakes complete; number, 1. Conditions, etc., may be obtained from Mr. T. B. Laing, town clerk, Council-chambers, Leith, on payment of a deposit of £1. 1s., which will be returned on receipt of a bona fide offer. Tenders by Nov. 26.

Brisbane.—Tenders are invited by the Deputy Postmaster-General for the supply and delivery at the Telegragh Office Yard, Thursday Island of 100 tubular wrought-iron telegraph poles to Specification No. 11 and Schedule No. 51, and also for the supply and delivery at the cable tanks, Thursday Island, of three nauts of submarine cable to Commonwealth Specification No. 8 (Queensland, No. 22) and Schedule No. 50. Tenders by Dec. 12. They must state the time required for delivery; this time will be counted from the date of the notification of the acceptance of the tender. Specifications and forms of tender can be obtained at the General Post Offices, Sydney, Melbourne, Brisbane, and Adelaide. Neither the lowest nor any tender will necessarily be accepted. Tenderers are required to note that Customs' duties must be included in all charges, as per clause 2 of the general conditions. All tenders sent by post must be registered.

RESULTS OF TENDERS.

Plymouth.—The Hart Accumulator Company have secured the contract from the War Office for the supply of 67 of their standard lighting-type cells, having a capacity of 600 ampere-hours.

Fulham.—The Council have accepted the tender of the British Thomson-Houston Company, at £492, for the supply and erection of a 3,000-volt main generator switchboard at their generating station.

Electric Lighting.—Messrs. Woods, Slacke, and Co., Blackburn, report the following contracts: Salford—complete electric lighting, including switchboards, arc lamps, etc., for half a mile of transit sheds for the Manchester Ship Canal Company; Newcastle-upon-Tyne—complete electric lighting, including switchboards, etc., at the new hospital, union workhouse; Rochdale—electric lighting of car-shed, including telephones, bells, etc.; Crewe—electric lighting of post office; York—electric light installation for city cattle market, and complete electric lighting, about 1,700 lights, including boilers, feed pumps, steam and exhaust piping, three engines and dynamos, main switchboards, motors, etc., at the York City Asylum.

APPOINTMENTS VACANT.

Junior Assistant for a firm of consulting engineers. See advertisement.

Assistant Electrical Engineer, Worksop Urban District Council. Salary, £150 per annum.

Mains Superintendent, Poplar electricity works. Salary, £120 per annum. Applications by Nov. 18. See advertisement.

Mains Assistant, Blackburn electricity works. Commencing salary, £130 per annum. Applications by Nov. 18. See advertisement.

Demonstrator in Engineering, London County Council Paddington Technical Institute. Applications by Nov. 23. See advertisement.

BUSINESS NOTES.

TRACTION.

Nottingham.—The Corporation have published the statutory notice of their intention to apply for parliamentary powers to construct several extensions of the tramways.

Shanghai.—The Municipality are again inviting tenders for the construction and working of 24 miles of electric tramways on the trolley system, double or single.

Colwyn Bay.—Good progress is being made with the line to Llandudno, which it is hoped to complete by March 1 next. The system will be about 8½ miles in length.

Accrington.—The Corporation have published a statutory notice of their intention to apply for parliamentary powers for a number of works, including electric tramways and lighting.

Derby.—An extension of the tramways from St. Peter's-street to Market-square has been decided upon at a cost of £3,470. The work will be carried out by J. G. White and Co., Limited.

Liverpool-Bolton.—This journey can be made by street car. The distance is 30 miles, and the journey extends over some eight systems. The fares total 1s. 9d., and the time occupied rather under four hours.

Margam (Glamorgan).—At a meeting of the Margam Council, the Chairman stated that a syndicate had been formed to obtain a provisional order for the construction of an electric tramway from Briton Ferry to Taibach.

Hindley.—At the meeting of the District Council it was reported that negotiations are proceeding between the Wigan Corporation and the South Lancashire Tramways Company with regard to the proposed Wigan-road route.

Aberdare.—The District Council have decided to apply for power to construct an electric tramway, to execute street widenings, and to erect a dust destructor, the total expenditure involved being between £93,000 and £94,000.

Monorail Construction Co.—A meeting of the Monorail Construction Company, Limited, has been called for the 22nd inst. to consider a resolution to increase the capital to £70,000 by the creation of 1,000 new shares of £10 each.

Exeter.—The first section of the electric tramways from St. David's Station to Liverydole will be completed by the first week in December,

Digitized by Google

and the St. Sidwell's section shortly afterwards, though they may not be open for traffic until the New Year.

Beckenham.—At the meeting of the Electric Lighting and Tramways Committee last week, the clerk produced the bond and agreement duly sealed by the British Electric Traction Company and the Electric and General Investment Company, Limited.

Darlington.—The working expenses of the trams from the commencement of running to Sept. 30 amounted to £2,595. 8s. 9d., and the receipts were £3,698. 0s. 11d. The number of passengers carried was 908,664, and the receipts per car mile were 7·249d.

Aston.—The Tramways Committee have decided, in reference to the Steelhouse-lane to Aston line, that covered cars should be ordered for the ordinary traffic of the line. One covered car has been running on the section for some time, and this has proved entirely successful.

Bradford.—A proposal to grant the tramway employés under the Corporation a week's holiday annually was on Monday considered by a sub committee, but no decision was arrived at. The question would affect about 1,000 men, and would involve about £1,500 increased expenditure.

Sunderland.—The receipts of the Corporation trams for the half-year amount to £35,223, an increase of £721 upon the same period last year. For October the passengers carried were 1,262,552, and the receipts £5,289, an increase on October last year of 59,954 passengers and £253 in receipts.

Dundalk.—The promoters of the tramway scheme have applied for a further extension of their order for 12 months. Having received an assurance that the promoters are proceeding with the financial part of the scheme, the Urban District Council unanimously resolved to consent to the extensions.

Calcutta.—The new line along Harrison-road is on the verge of completion. It is expected to be of great service, and extensive patronage is probable. It is reported as not unlikely that eventually the Harrison-road line will be extended westwards over the Howrah floating bridge to join on with the system of tramways to be undertaken on the further side of the river.

Ashton.—The Tramway Sub-Committee having had a satisfactory conference with the Stalybridge, etc., Tramway and Electricity Board relative to inter-running and the construction of the Scotland-street and Old-street line, the borough surveyor and electrical engineer have been instructed to prepare the necessary plans and specifications for the construction and equipment of the route.

Bishop Auckland.—The Durham County Council have received notice that the United Kingdom Tramway, Light Railway, and Electrical Syndicate, Limited, has transferred the Bishop Auckland, Shildon, and Spennymoor tramway to the Public Undertakings Limited. The Council have assented to a 12 months' extension for the completion of the Houghton-le-Spring tramways.

Aston.—Another section of the tramways was opened on Tuesday. The new section extends from Aston Cross to Gravelly Hill. The cars are of the single-deck type, so as to pass under the railway bridge at Aston Station. With the commencement of this service the whole of the steam cars which formerly belonged to the Birmingham and Aston Tramway Company have been taken off the track.

Torquay.—The chairman of the Dolter Company (Mr. Hugh Lubbock) and Mr. W. C. Hawtayne had an interview with the Electric Lighting Committee the other day, and provided that current is available a definite promise was given on behalf of the company that the electric trams should commence running by June next. The company will be in a position to begin the work of laying the lines immediately after Christmas.

New York Underground Railway.—The *Glasgow Herald* says "The new high-speed electric locomotive was tested at Schenectady on Saturday, and more than fulfilled the expectations of the company's officials. The engine attained a speed of 72 miles an hour, and it is estimated will be able to travel at 60 miles an hour with a 500-ton load. Mr. Wilgus, vice-president of the railroad, declared that the engine solved for all time the problem of electric traction at high speed."

Proposed Electric Railway.—A scheme is reported to be on foot for a railway from Pontefract to Immingham. A survey has been made, and the surrounding landowners are understood to be favourably disposed. According to the plans the proposed route is practically a straight one, extending over a distance of 49¼ miles. The South Yorkshire coal collieries are expected to provide a substantial revenue. It has not yet been decided whether electric or steam power should be employed.

Snowdon, etc., Light Railway.—At an extraordinary meeting of the North Wales Narrow-Gauge Railways Company, approval was given to an agreement between the Portmadoc, Beddgelert, and South Snowdon Railway Company, the North Wales Power and Traction Company, Limited, and the North Wales Narrow-Gauge Railways Company containing the basis of working arrangements between the companies.

The Underground.—The District Railway Company are notifying their season-ticket holders that they cannot renew beyond Dec. 31. After that the zone system comes into operation. A few electric trains will possibly be running on New Year's Day; but for some weeks or months steam will continue in a lessening quantity. The zone (single) fares will be: 2d. any station between Aldgate and Hammersmith, and Hammersmith and Ealing, 3d. between Aldgate and Ealing and between Hammersmith and Whitechapel, and 4d. between Whitechapel and Ealing.

Huddersfield.—The traffic receipts from Nov. 1, 1903, to Sept. 30, 1904, amount to £60,801. 4s. 5d., being an increase of £4,937. 6s. 8½d. over the corresponding period. The total is made up as follows: receipts from passengers, £60,084. 12s. 10d.; parcels, £619. 10s. 7d.; miscellaneous, £97. 1s.—making a total of £60,801. 4s. 5d. The mileage run during this period amounts to 1,522,919 miles, an increase over the corresponding period of 112,141 miles. The number of passengers carried was 11,464,033, an increase of 1,110,320 over the corresponding period.

Cheltenham.—The Town Council have adopted a recommendation of the Highways Committee that the Council should agree to bear the cost of raising or lowering the levels of the road along which the extensions of the light railway are being laid where such is required by the Council, for the purpose of improving the gradient of the road, but that the company be required to bear the cost of raising or lowering the level of the road to coincide with the level of the railway track fixed by the borough surveyor, where such alteration of level is in the opinion of the surveyor necessary in order to make a satisfactory track. There are a good many undulations, and the object is to secure a level road.

Weymouth.—At the meeting of the Dorset County Council, the Works Committee reported an intimation from the Weymouth Corporation of the latter's intention to formulate a scheme of tramways leading to the village of Wyke Regis, and thence to Portland on the one hand, and on the other through the village of Broadwey to the bottom of Ridgeway Hill, and they asked the Council to consent. The Corporation had not yet formulated a definite scheme, and pending this the committee could not recommend the Council to entertain the question of giving any consent under the House of Commons Standing Orders, but they suggested that the Council should invite the Corporation to submit full particulars.

London United Tramways Co.—The Board of Trade have confirmed the order made by the Light Railway Commissioners, authorising the construction of light railways in the county of Middlesex between Hounslow and Cranford and between Heston, Hounslow, Hanworth, Twickenham, and Sunbury Cross, being extensions of the existing and authorised undertaking of the London United Tramways (1901), Limited. The Hammersmith Borough Council have received a communication from the town clerk of Ealing asking whether the Council will join the committee of local authorities which it is proposed to appoint for the purpose of dealing with the tramway noise, and, if so, whether they will contribute towards the costs of any proceedings that may be decided upon. The Parliamentary Committee of the Borough Council express their sympathy with the movement, but do not recommend any financial assistance at present.

Newport.—The accident on the Stow-hill section was referred to at a meeting of the Town Council by Mr. W. H. Brown, chairman of the Electricity and Tramways Committee, who deprecated the sensational way in which a Newport newspaper had reported the occurrence. He read a report from the borough electrical engineer, explaining that the accident was caused by the greasy state of the rails, consequent upon a drizzling rain and falling leaves, and through a piece of wood choking the sanding apparatus on the car. The danger of a recurrence of such an accident would be removed by stationing a man on Stow-hill to spread sand on the rails whenever necessary. He added that the sum of £31. 11s. 9d. had been taken in the three days since the section had been opened. Several members expressed the opinion that the accident was distinctly alarming, and that it was necessary to reassure the public that such steps would be taken as would prevent such another accident occurring.

Manchester.—Plans are in preparation, and will be deposited before the end of the month, for an underground railway through Manchester. The scheme has not yet secured the approval of the Corporation, although in view of the present congested condition of the traffic through the main streets of the city this will probably be obtained. The author of the scheme is Mr. W. A. Jackson, architect and engineer, who contends that the railway would not only be a commercial success, but a great public benefit. Instead of a circular route he begins with a cross route, with subsidiary lines, getting in touch with the tramlines at eight places. By through routes from one district to another, Mr. Jackson thinks it will only require three minutes for a journey that at present occupies 20 minutes. The system, he contends, will obviate the necessity of spending large sums of money for the widening of main thoroughfares. The total length of tunnelling would be 2½ miles, and the estimated cost is three quarters of a million for the single-deck cars.—*Financial Times.*

Hastings.—The Hastings and District Electric Tramways Company yesterday opened their subscription list, which will close on or before Monday next. The system will comprise nearly 20 miles of track, and besides running along the front of Hastings and St. Leonards, there will be a line to their rapidly-rising neighbour, Bexhill, thus supplying a valuable means of communication between these popular resorts. Besides this, there will be a circular route passing through Baldslow and Ore, affording a delightful country trip. According to the census of 1901, the normal population of the municipal borough of Hastings was over 65,000, and that of Bexhill more than 12,000, besides which there are, of course, hosts of visitors, who will doubtless appreciate the new facilities for seeing the surrounding country. The consulting engineers, Messrs. Kincaid, Waller, Manville, and Dawson, estimate that, upon a conservative calculation, the system will show an annual net profit of £30,000, with the possibility of a considerably larger surplus. The contractors are Messrs. Dick, Kerr, and Co.

Erith.—It was reported at the meeting of the Urban Council that as the result of information obtained by the recent inspection of the tramways at Leicester, Derby, Sheffield, Manchester, and Preston, and the several engineering works which they visited, the Tramways Committee have made several suggestions to the consulting engineers relative to the construction, fitting, and equipment of the tramcars for the Council's tramways. The committee have gone through the draft specification for the tramcars with Mr. Hawtayne, and recommend that the specification be approved and an advertisement for tenders issued. The consulting engineers reported that Messrs.

Digitized by Google

Blackwell and Co., the contractors, had started the work under contracts Nos. 1 and 2, in Bexley-road, Northumberland Heath, and in Abbey-road, Abbey Wood, and that material was on the site sufficient to allow good progress being made. They also reported the progress made by the contractors for the Lower-road bridge. The concrete foundations for the abutments and wing walls had been satisfactorily completed. The committee have instructed the clerk to make application to the Bexley Urban District Council for permission to make a visit of inspection of the Bexley tramways.

Cardiff.—A chartered accountant deals in the *Western Mail* with the tramway finances, which have caused a good deal of discussion. On the question of depreciation, he remarks that there is not only depreciation through continued use, but also the risk of obsolescence to be considered. The capital charges debited against the revenue account for the year ending March 31, 1904, were: loans fund account (1902) instalments, £11,593. 8s. 3d.; and loan repayment, Public Works Loan Board, £2,490. 9s. 2d.—total, £14,083. 17s. 5d. In the evidence given before the Joint Select Committee on Municipal Trading it transpired that the Glasgow Corporation tramways revenue account was charged with both the repayment instalments and full depreciation; but the Glasgow tramways accounts showed enormous profits, and this partly owing to the fact that some items of expenditure properly chargeable against the tramways appeared to have been debited to other accounts. Basing his calculations on the amount of the capital outlay at March 31, 1903, the writer considers £24,315 a fair annual amount to allow for depreciation and renewals. He allows 1½ per cent. for new buildings, 2 per cent. for the old depôts, 10 per cent. for plant and machinery, 2½ per cent. for conduits and cables, 5 per cent. for engineering charges, 2½ per cent. for overhead equipment, 7½ per cent. for cars and rolling-stock, etc. On this basis the undertaking would show for the year ending March 31 last a deficit of £4,913. 4s. 5d., instead of the surplus of £5,317. 18s. 2d. shown by the accounts.

Snowdon-Bettws-y-Coed.—Sir Herbert Jekyll, on behalf of the Board of Trade, heard objections to the confirmation of the order passed by the Light Railway Commissioners for a light railway from Snowdon to Bettws-y-Coed, a distance of 13 miles, in what was described as the loveliest part of North Wales. The scheme was opposed by the National Trust for Places of Historic Interest or Natural Beauty, the Co-operative Holiday Association, the Alpine Club, and several others. The objectors' contention was that the beauty of the Snowdon district was so exceptional and its attraction for a large number of visitors so great as to deserve protection from a railway. This district was attractive on account of natural qualities, which the proposed railway would entirely destroy. Mr. Honoratus Lloyd, for the promoters, said they had done everything to avoid interfering with the natural beauties of the neighbourhood, and the whole of the landowners affected were in favour of the scheme. Mr. Banks contended that the workers of the country were entitled to have some places left in which they could have a quiet holiday undisturbed by the noise of gongs and tramcars, which would bring in their train the cheap trippers. Mr. Lloyd said the railway already not only carried people to Snowdon but up the mountain itself, and the beauty of the scenery would not be affected by a little narrow-gauge electric railway. The Board of Trade will give a decision shortly. The question was raised by the Urban District Council of Bettws-y-Coed as to the running of trains on Sundays. Sir Herbert Jekyll said the Board had never put in a clause against the running of trains on Sundays, and although he should reserve his decision, it was not likely that the Board would make an exception in this case.

Colchester.—At the meeting of the Town Council the Finance Committee reported having accepted an offer from the Ecclesiastical Commission to advance £50,000 (part of the loan for tramways) at £4 per cent., the payment of interest and repayment of principal to be made by 48 half-yearly payments of principal and interest combined. A sad fatality—the first since the opening of the system—occurred on the Corporation tramways, the victim being a little girl about six years of age, named Emily May Secrett. The child crossed the road immediately in front of an oncoming car, which had slowed down somewhat to pass the points. The driver sounded his gong and shouted to the child, and applied the brake instantly, but it was too late to save her. The front of the car struck her and knocked her down, and the lifeguard descended, but, instead of picking the unfortunate child up, the apparatus was caught and jammed by a portion of her clothing, with the result that the body was forced along for a foot or two, and then crushed by the lifeguard, which was forced over her body and then fell again. A jack was hastily sent for, but proved too large to be used effectively to raise the car, and a foreman of the car depôt ran for another. Meantime, however, a plank was secured, and the jack, being laid on its side, was used as a prise, the car being by this means lifted and the body of the child taken from underneath it. When taken out, the child was breathing, but unconscious, and death ensued in a few moments, the base of the skull being badly fractured, while the right arm and left leg were broken, and the body had sustained other terrible injuries. The pilot board of the tramcar was broken—probably by the force and suddenness with which the driver applied the brake, the car being brought to a standstill with such suddenness as to almost throw the conductor from his feet. At the inquest the jury returned a verdict of "Accidental death," and attributed no blame whatever to the driver, who they considered did everything possible to avert the fatality. With regard to the suitability of the lifeguard, they suggested that two springs should be fitted to keep it down, and the foreman added that it was a remarkable thing that the body of a small child should be able to press up the present apparatus. The jury also suggested to the Tramways Committee the provision of jacks on every car. At a special meeting of the Town Council on Tuesday it was proposed that powers should be applied for to authorise an extension of the tramways for about half a mile. It was stated that the new section would serve a populous neighbourhood. As, however, owing to various causes, less than two-thirds of the Council were present, the matter had to be deferred.

London County Council.—At its meeting on Tuesday the Council considered the recommendation of the Highways Committee that powers be sought to carry the tramways over Blackfriars Bridge and along the Embankment so as to effect junctions with other lines, and after some discussion the proposal was agreed to unanimously. On the same day the Streets Committee of the City Corporation discussed the proposals of the County Council in regard to this scheme. Representatives attended from the County Council and from the Bridge House Estates Committee, the latter being apparently adverse to the project. Several members of the Streets Committee favoured the scheme, and in the end the committee decided to hold another meeting shortly, when a definite recommendation to the Court of Common Council will be decided upon. The Highways Committee recommend that an agreement be entered into with the North Metropolitan Tramways Company for the working by the latter of the authorised tramway in Rosebery-avenue. It is proposed that the company shall pay as rent a certain proportion of the cost of construction. The estimated cost of construction is £10,285 for the temporary horse system, and £26,000 for the conduit electrical system. In connection with the tramways taken over from the London, Deptford, and Greenwich Tramways Company, it is proposed to discontinue the routes from St. James's Church to Tower Bridge-road and from Raymouth-road to the canal bridge, Old Kent-road, as these are not much used. In regard to the remainder of this tramway, the Highways Committee have under consideration the question of improving the service by electrification or otherwise. Apart from this undertaking, the Council's system has produced £394,518 from April 1 to the 5th inst., as against £318,593 last year. The Council have replied to the Bostall Estate Protection Association that the Council have under consideration the question of proceeding forthwith with the street widenings required in connection with the authorised tramways between Beresford-square, Woolwich, and the county boundary, Abbey Wood. So soon as these shall have been completed, the construction of the line will be commenced. A public meeting at Blackheath the other day entered a protest against the proposal of the Council to construct a tramway from Deptford across Blackheath to Shooter's Hill, and passed a resolution in support of an alternative route from the existing tramway in Woolwich-road up Westcombe-hill, and thence by the Old Dover-road and Shooter's Hill-road to Shooter's Hill. It was decided to send copies of the resolution to the Council and to the Lewisham Borough Council.

Lowestoft.—In presenting a report and accounts for the 14 months' trading of the tramways undertaking to the Council last week, the Chairman and General Manager explained that the accounts were made up from the opening of the system on July 22, 1903, to Sept. 30, 1904, so as to bring the tramways department accounts into line with other accounts of the Corporation, which close on the latter date. The revenue account, after paying the total working expenses, show a gross profit of £4,801. 11s. 2d., to which must be added the borough fund grant £145, giving a total of £4,946. 11s. 2d. Interest on capital and income tax amounts to £3 331. 14s. 7d., sinking fund charges £875. 3s. 9d.; and the committee recommended that the balance be divided as follows—viz.: to the credit of reserve or renewal account, £350; repay grant from borough fund, £145; carry forward to next year's account, £244. 12s. 10d. The revenue account showed traffic receipts £14,086. 12s. 4d., and advertisements £425. 4s. 7d.—total, £14 511. 16s. 11d. Traffic expenses totalled £4,050. 6s. 10d. (including £3,231. 1s. 5d. wages of inspectors, motormen, conductors, etc.), general expenses £1,250. 11s. 11d., general repairs and maintenance £969. 16s. 1d., power expenses £3,439. 10s. 11d.—total, £9,710. 5s. 9d.; balance carried to net revenue account £4,801. 11s. 2d.—total, £14,511. 16s. 11d. The revenue profit was dealt with as follows: interest on capital £3,254. 7s. 3d., income tax £77. 7s. 2d., balance to appropriation account £1,614. 16s. 7d. The last-named amount was appropriated in the following manner: first instalment of contribution to sinking fund £875. 3s. 9d., reserve or renewal fund £350, balance carried forward to next account £389. 12s. 10d. The capital account totals £75 894. 4s., and the Electric Lighting Committee pay interest and sinking fund charges on £10,000. The balance-sheet showed liabilities £78 897. 13s. 11d., and the following items appeared under the heading of property, assets, and outlay: cost of existing works—viz., permanent way, £36,280. 14s. 6d.; mains and electric equipment, £6,939. 8s. 5d.; generating plant, machinery, and tools, £9,678. 10s. 11d.; rolling-stock, £11,407. 16s. 11d.; buildings, £7,034. 2s. 9d.; office furniture, etc., £28. 4s. 10d.; sundry equipment, £326. 6s 6d.; preliminary expenses, £786. 18s. 7d.; engineers' fees, £3,343. 14s.—total, £75 815. 17s. 5d. By investment: on account of sinking fund, £875. 3s. 9d.; stores in hand, £217. 4s. 5d.; sundry debtors, £340. 13s. 6d.; unexpired licenses insurance, and rates and taxes, £216. 15s. 10d.; cash at bank £1,401. 12s. 1d.; cash in hand, £30. 6s. 11d.—total, £78,897 13s. 11d. The accounts were audited by Mr. Joseph E. Tubbs, F.C.A., of London, who in his report stated that in addition to the sum of £875. 3s. 9d. appropriated to the sinking fund, £350 had been transferred to reserve or renewals account. The report continued: "No special provision has been made in these accounts for depreciation beyond the above-named sums, but this should be considered and dealt with in the future." The net balance after 14 months' working is £389. 12s. 10d. The following statistics were also presented: car miles, 359,435; passengers carried, 3,128,867; total number of units used, 366,885; number of units per car mile, 1·02; average traffic revenue per car mile, 9·40d.; average total, 9·68d.; average car miles per car per day, 75·78; average working expenses per car mile, excluding power cost, 4·18d.; average working expenses per car mile, including power cost, 6·48d.; average fare paid per passenger, 1·08d.; average number of passengers per car mile, 8·70; passengers at 2d., 249,278; passengers at 1d., 2,871,062; passenger workmen at 1d.,

Digitized by Google

8,257; private hire of cars, £11. 0s. 3d. The matter of the construction of the East Anglian light railways from Lowestoft to Kessingland had been considered by the Tramways Committee, and further deferred. The report was adopted. The accounts show an excellent result for the initial year's working.

LIGHTING AND GENERAL.

Electrical Trades Union.—A branch of this union is to be formed at Hull.

Spalding.—An application for a provisional order for electric lighting is now being made by the Urban District Council.

Southport.—Electric light is being fixed on one of the Corporation's bowling green, so that play may be continued after dark.

Gosport.—The proposed provisional order of the Gosport Electric Lighting Company has been approved by the Urban District Council.

Church Stretton.—The electricity works, which have been erected at a cost of between £5,000 to £6,000, are completed, and the plant is being tested.

West India and Panama Telegraph Co.—The directors recommend a dividend of 7s. per share on account of arrears of dividend on the first preference shares.

Govan.—The Secretary for Scotland has consented to the borrowing of £47,000 for electric lighting, making a total sum for the electric lighting scheme of £127,000.

Brentford.—The Board will next week consider the advisability of adopting a system of electric lighting throughout the workhouse, and, if expedient, the whole of the institutions of the Guardians.

Lowestoft.—There are now connected to the mains 554 consumers, representing 27,653 8-c.p. lamps. During the month eight new consumers have been connected, representing 305 8-c.p. lamps.

Central Electric Supply Co.—The transfer books of the 4 per cent. guaranteed debenture stock will be closed from Nov. 17 to Nov. 30 inclusive, preparatory to the payment of interest due Dec. 1.

Preesall.—At a recent meeting of the Urban Council a letter was read from Mr. O. Hanson, electrical engineer, Fleetwood, intimating that a company was about to be formed to supply electricity in Over Wyre district.

Lytham.—A committee of the Council have had a conference with the St. Annes authority to consider the latter's proposal to supply Lytham with electricity in bulk. The matter is now under the consideration of the Council.

Inverness.—Mr. E. J. Williams, resident engineer for the North of Scotland Electric Light and Power Company, Limited, has submitted to the Town Council specification of the plant, etc., for the town electric installation.

British Trade with South America.—Senor Pedro A. Costa, of Buenos Ayres, is issuing for the Buenos Ayres and South American Agency, Mansion House-chambers, Queen Victoria-street, a series of notes and comments on the above subject.

Bideford.—The Town Council have received several notices of intention to apply for a provisional order to supply Bideford with electricity, and asking for the Council's consent, and they have replied that the Council themselves intended applying for an order.

Perth.—The Town Council have decided to call for offers for the erection of additional electrical plant, suggested by Mr. Lambert, and also to apply to the Secretary for Scotland for authority to borrow to the extent of £6,000 to meet the cost of said plant.

Wednesbury.—The Town Council have agreed to the extension of the electricity main at a cost of £85. Since the last meeting of the Council 500 additional lamps have been applied for. There are now altogether some 1,600 lamps connected to the mains.

Tredegar.—The District Council have accepted the offer of Mr. Tallis, Tredegar Company, to fix an installation of electric light at Pochin for £35, on the understanding that the light be turned on for the convenience of the men going to work in the morning.

Clewer.—The Windsor Electrical Installation Company, Limited, intend to apply for a provisional order to authorise them to supply electrical energy for public and private purposes within the parishes of Clewer Without and Old Windsor in the rural district of Windsor.

Shrewsbury.—The number of units of electric current sold during the last quarter shows an increase of 8,764 units, compared with the corresponding quarter last year. Extensions will be required to the electricity works, both with regard to buildings and machinery, and a report is being prepared.

Great Western Railway.—The Howard Conduit Company, Limited, Trafford Park, Manchester, report an order, through Messrs. Siemens Bros., for the troughing required in connection with Messrs. Kennedy and Jenkin's specification for the Great Western Railway electrification.

Cheltenham.—The report of Mr. Swinburne, noted in our last and dealt with in another column of the present issue, will come before the Council on the 23rd inst. In the meantime, Mr. Ley Wood has replaced Mr. Norman as chairman of the Electricity Committee, and it is anticipated that quieter counsels will prevail.

Swansea Telephones.—The rentals due for the 12 months ending Nov. 5, 1904, were £3,979. 0s. 9d. Of that amount £3,135. 9s. 11d. has been actually collected, leaving £845. 10s. 10d. to be collected. Included in the last-named figure is £89. 17s. 4d. for police private telephones, which only became due on Nov. 5.

Beckenham.—At the last meeting the following subjects were brought forward and adjourned till the next meeting: supply of current for Penge tramways; purchase of Crystal Palace Electric Lighting Company's rights of supplying Beckenham; and the extension of lease of the electric lighting undertaking.

Life-Saving Apparatus.—It is reported that an effort is being made to induce the United States Government to stretch an electric light wire along the whole extent of the Cape Cod coast and maintain power through it, so that life-savers, upon any emergency of a wreck, could apply an electric searchlight to facilitate life-saving operations.

Shildon.—The Urban District Council are urging the Northern Counties Electric Supply Company to sign an agreement to complete their scheme by January. The Council are prepared, in case of the work being delayed by wet weather, to grant a reasonable extension for the completion of the scheme. The company have already expended £6,000.

London County Council.—The Council are establishing a residential home for mentally defective boys at Brixton, and have entered into an agreement with the South London Electric Supply Company, who will supply current at 4d. per unit. A number of applications to lay mains, etc., in various parts of the Metropolis were agreed to on Tuesday.

Epsom.—The Lighting Committee have informed the owners of the Alexandra Park Estate that the Council would proceed in due course to light by electricity the portion of the Alexandra-road on which the estate abuts, and would consider the question of lighting Ashdown and Kingston roads on the terms previously discussed with the estate agents and contractors.

Stock Exchange.—Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to Telephone Company of Egypt, Limited, £60,000 4½ per cent. debenture stock, and to allow the Montreal Light, Heat, and Power Company's 7,500,000dol. 4½ per cent. bonds to be quoted in the official list.

New Barnet.—At a recent meeting of the New Barnet Tradesmen's Association a letter was read stating that the Council had resolved not to proceed at present with the National Construction Company's scheme, and, further, that before the Council completed any arrangements with any electric lighting company they would convene a meeting and place the details before the ratepayers.

Chester-le-Street.—The Rural District Council will at their next meeting discuss an application of the County of Durham Electrical Power Distribution Company, Limited, to support their application at the Board of Trade for a provisional order under the Electric Lighting Acts, 1882, 1888, 1889, to supply electricity within the area of the Council's jurisdiction. The Durham Rural District Council have consented to a similar application for an order for their area.

Durham.—At the last County Council's meeting the Clerk read a communication from the Local Government Board in reference to the proposed county electric supply, stating that the Board was not aware of any statutory authority whereby the county could carry out a scheme of electric supply. The letter was ordered to be entered in the minutes, and the report of the Electricity Supply Committee was, in the circumstances, referred back for further consideration.

Ashton.—The Town Council have resolved to adopt the following scale—viz: (1) for power, the present rate of 1½d. per unit; (2) to consumers satisfying the committee or electrical engineer as to the continuous running of their motors, whose consumption exceeds 500 units per quarter, but does not exceed 1,000 units per quarter, the rate of 1½d. per unit; (3) to consumers complying with Clause 2, and whose consumption exceeds 1,000 units per quarter, 1d. per unit.

Grangemouth.—The Town Council have for some time had under consideration the propriety of lighting the burgh with electricity, and at the ordinary meeting on 15th inst. they resolved, on the recommendation of the Lighting Committee, to postpone making application to Parliament for a provisional order until next session, and meantime to procure information as to the position of other burghs, and the terms likely to be granted them by the Scottish Central Electric Power Company.

Burslem.—The Local Government Board have expressed their willingness to sanction the loan for electric lighting and dust destructor purposes. Providing that the Tunstall Urban District Council agree, their provisional order will be revoked and a new provisional order obtained by Burslem on the same conditions as the Burslem Extension Order, 1899. A special meeting of the Council is to be held on Nov. 30 for the purpose of passing the required resolutions.

Colchester.—At the last meeting of the Electric Light and Power Committee, it was reported that as the result of a canvass 130 new consumers had been obtained, and that the premises of 63 thereof had been already connected. The following statistics are taken from the report of the electrical engineer: output of electricity in units during September, 1904, 75,700 (1903, 28,705); number of consumers at end of September, 551 (374); total number of 8 c.p. lamps connected, 27,159 (23,427).

New Issues.—The Llandudno and Colwyn Bay Electric Traction Company, with an authorised capital of £150,000 and an authorised debenture issue of £60,000, offer for sale 1,000 5 per cent. debentures of £50 each and 49,440 ordinary shares of £1 each. Of the balance of the share capital 10,500 shares have been issued for cash, and 90,000 are reserved for future issue. The route of the light railway to be constructed is from near Colwyn Bay Station to the West-parade, Llandudno, a length of 8½ miles.

London Gazette.—Applications have been made for electric lighting provisional orders by the following: Kingsbury Urban District Council; Andover Corporation; Conway Corporation; Litherland Urban District Council; and Penmaenmawr Urban District Council. A petition confirming a special resolution reducing the capital of the Nernst Electric Light Limited and Reduced Company from £320,000 to £90,000 will be heard before Mr. Justice Swinfen Eady, at the Royal Courts of Justice, on Nov. 29, 1904.

Digitized by Google

Cardiff.—At the last Council meeting Alderman Carey said that next year they would have to make provision for 45,000 extra candle-power lamps, including 16,000 candle-power lamps for Cathays Park. In the year 1900 the Corporation had generated something like half a million units of electricity, but their returns up to March, 1904, showed that they had generated about 3,000,000 units, so that in less than four years they had been called upon to supply six times the original demand.

Hammersmith.—The last report shows that the premises of 11 additional consumers, representing a maximum of 245 8-c.p. lamps, have been connected to the mains, that three consumers have been disconnected, and that the present number of consumers taking current from the mains is 1,519. The Borough Council have allowed the Post-master-General to place an underground telegraphic line along the south side of Uxbridge-road, and an overground telegraphic line along South-street and Waterloo-street.

Dundee.—The motive power in Messrs. James Prain and Sons' jute works, which are made up of two sections, one on each side of the street, consists of two steam-engines, developing about 400 h.p. The load on the engines was rather unequally distributed, and electric power is being installed, which will be conducive to more economical working. A generator of 80 kw. will be actuated by one of the existing engines, and the current will be conveyed across the street by an underground cable to a 100-h.p. motor. The drive will be taken up by a system of wheel gearing, and the entire factory will be actuated by its agency. The contract for the electric plant has been obtained by Messrs. D. W. Ritchie and Co., electrical engineers, Ward-road.

Newport (Mon.).—An enquiry has been held into the application of the Corporation for sanction to borrow £17,825 for purposes of electric lighting extensions and power supply. Mr. A. A. Newman, town clerk, and Mr. H. Collins Bishop, borough electrical engineer, gave evidence for the Corporation, the latter stating that they estimated the profits of the electrical undertaking for the current year at between £1,000 and £2,000. The lamp connections had increased from 7,278 at the end of the first year (1896) to 65,000 at the end of September, 1904. The Llanarth-street works were not to be superseded. It was proposed to erect a sub-station on Stow-hill, and automatic feeders would be placed in various parts of the town.

Poland.—The French Consul-General at Warsaw, in his report for 1903, states that there is a good opening in Poland for all kinds of electrical apparatus, such as motors, batteries, dynamos, accumulators, electric lighting materials, ornamental fittings, incandescent lamps, arc lamps, electric toys and bells, telephone material, etc. These goods are now imported mainly from Berlin and Vienna. The trade in electrical apparatus is not very large at present, but it is bound to extend, owing to the recent foundation of a central generating station. Despite the extension of the contract with a Dessau company for lighting the streets of Warsaw by gas, the use of electric light is becoming general in private houses and business establishments.

King's Lynn.—The electrical engineer reported at the October meeting that since the last meeting applications had been received for a supply to 282 additional lamps of 8 c.p., or equivalent, making a total of 19,968 from private consumers, and that there are now 485 private connections to the mains, being an increase of five. The applications included two additional motors. The engineer submitted the following statement—viz.: units generated, September, 1904, 36,575 (1903, 31,263); total units sold to private consumers (light and power), 26,449 (16,556); units sold at power rates, 12,518 (5,230); cost of fuel, stores, repairs, and wages at station, £113. 19s. 3d. (£97. 13s. 9d.); cost per unit generated, 0·7478d. (0·7499d.); wages of lamplighters and outside staff, £20. 11s. 4d. (£18. 10s. 1d.).

Pollokshaws.—It is reported that the Pollokshaws and the Glasgow Councils have now come to terms for the supply of electricity to the burgh. The agreement is to the effect that (1) if the Town Council obtain a provisional order from the Board of Trade to supply electricity, with a clause authorising them to transfer their powers to the Corporation, the latter will pay the expenses of the Town Council up to £400; (2) that if the Town Council obtain an order, but without authority to transfer it to the Corporation, their expenses will be paid by the Corporation only to the extent of £200; and (3) that if the Town Council obtain an order, but carry out the work themselves or transfer their authority to a body other than the Corporation, no contribution will be made by the Corporation towards their expenses.

Ayr.—The monthly report by the burgh electrical engineer, Mr. Roland Marshall, contains the following figures: Number of consumers, as per last report, 320; number of consumers connected during the month, 4—total, 324. Number of lamps connected, as per last report, 34,591; number of lamps connected during month, 115—total, 34,706. Units generated, as per last report, 378,344; units generated during month, 123,298—total, 501,642. Units generated for corresponding period last year, 455,378—increase, 46,264. The above figures show satisfactory progress for the first six months of the year, especially in the number of lamps connected, which show an increase of 6,405, or 21 per cent. in excess of the number connected for the same period last year, while the number of units generated show an increase of 46,264.

German Atlantic Telegraphy.—The German Atlantic Telegraph Company, which is now taking over the Borkum-Vigo cable undertaking of the German Marine Telegraph Company, is making a fresh issue of shares to the extent of £200,000 for this purpose. It appears, says the *Financial Times*, that the subsidy receivable from the German Government for the use of the two Atlantic cables will amount to £81,000 in 1905, £82,500 in 1906, and £84,000 in 1907. The directors state that the receipts for the first 10 months of the present year show an increase of £14,500 over the corresponding period of 1903, and this must be attributed to the bringing of the second cable into operation. The company, which has a combined share and bond capital of £2,200,000, paid a dividend of 5½ per cent. for 1903, as against 5 per cent. in 1902, and 4½ per cent. in 1901.

Chelsea.—At the last meeting of the Guardians the General Committee reported that having regard to an admitted breach of contract by the contractor for the electric wiring at the infirmary, the committee recommended that, to avoid a disturbance of the infirmary patients by the rewiring of the wards, Mr. Mickleburgh be called upon to pay £25 for supervision of the work still to be completed and for a further inspection of the finished work; that at his own cost certain portions of the wire be taken out and be submitted to an independent firm of cablemakers to be tested; that if the cable be found satisfactory, the remainder of the wiring, including any to be replaced, be carried out in strict accordance with the specification, the whole work being approved by the architects; and that Mr. Mickleburgh be required to extend his guarantee to six years and to leave £100 in the hands of the Guardians for two years, to be used by them in case of his failure to rectify any defects which may arise during the two years. The recommendation was adopted.

Macclesfield.—In reply to a letter from the Board of Trade asking what steps had been taken by the Corporation to carry out their obligations under the provisional order, the Council have informed the Board that they had carefully considered different schemes which had been submitted to them, but that they had not been able at present to adopt either of them, being of opinion, with a view of the large financial undertaking and responsibilities of the Corporation, that the present was not an opportune time for the undertaking by the Council of a large electrical installation for the borough. An amendment "That the British Westinghouse Company, Limited, Messrs. Crompton and Co., Limited, and the Industrial Engineering Company, Limited, be asked to tender for the installation of an electricity supply both with and without gas producers on the lines laid down in Messrs. Crompton and Co.'s scheme," was discussed at the last meeting and negatived. The Council also declined Messrs. Foote and Milne's proposals as to the financial part of the scheme.

Huddersfield.—The annual statement of the electricity department for the year ending Dec. 31, 1903, shows a surplus balance of £3,915. This amount carried to the depreciation and contingencies account makes the latter £11,853. The average cost of production was lower, and the number of lamps connected was larger than in any previous year, no less than 18,661 additional 8-c.p. lamps having been connected. During the year the committee reduced the charges for meter rents by one-half, which will represent a loss of revenue of approximately £800 per annum, and they have reduced the initial charges for energy for motive power purposes by 20 per cent. This should still further encourage the use of electricity for motive power. During the present year the mains have been considerably extended. The Corporation have, after several years' negotiations, secured provisional orders for the supply of electricity to the area of the Lunthwaite and the Golcar Urban District Councils, the main object in obtaining these orders being to interconnect the districts of Crosland Moor and Longwood, which these areas dissected. Mains have already been laid from Crosland Moor to Milnsbridge, and it is anticipated during the present year will be carried forward to interconnect the existing mains.

India and Burma.—Major Joly de Lotbiniére's report on the utilisation of the Periyar water power to supply electricity to Madras has been considered by the Madras Government, and is now before the Government of India for orders. *Indian Engineering* says: "We are assured that there is no doubt now that Government will approve of the Mussoorie electrical scheme, since Major Joly de Lotbiniére has sent in a favourable report regarding it. However, it is more to the purpose to learn that Government will advertise for tenders shortly. Messrs. Johnson and Phillips, through Messrs. Balmer, Lawrie, and Co., of Calcutta, have supplied the transmission plant for mining work at the Ruby Mines in Burma. Briefly, the plant may be described as 'two-phase, two miles transmission, 170 h.p., 2,000 volts, 60 periods.' The approximate price per horse-power of the plant delivered is £17, and there are four such plants now running. They have worked without a hitch from the commencement, and the installation furnishes a striking example of how, by the adoption of electricity, an undertaking which could not previously pay dividends was made a great success. Before installing the electric transmission plant, it cost £6,000 per annum at the Ruby Mines for fuel and lighting, and the chairman of the company went so far as to say in public that if worked in the old-fashioned way the concern would never have been placed on a paying footing."

Dover.—An enquiry has been held into an application for sanction to borrow £24,475 for the electricity undertaking extension. The Town Clerk said the Corporation had borrowed £150,000 for the purchase of the works. The loan now asked for consisted of an item of £7,715. Mr. Woodman gave the following particulars: under the head of plant—80 per cent. of the cost of new 400-kw. Ferranti engine set, £2,680; condenser valves, £135; steel tubes, £29; inspection fee, £15. 15s.; cast-iron pipes and work in connection with Ferranti set, £114; sundry invoices, £26. 12s. 6d.; salaries and wages, £200. 10s.; sundry stores, £13. 5s.—total, £3,214. 2s. 6d.; mains, including cost of laying, £2,878. 1s. 7d.; meters and indicators, £355. 15s. 11d.; electrical instruments, including a high-tension switchboard, £675. 6s. 10d.; transformers, £12. 7s. 2d.; street lamps, £26. 14s. 11d.; accumulators, £1. 13s. 4d. This accounted for a total of £7,714. 17s. of the £7,715 to be borrowed. The next item of the loan was £11,260, capital expenditure January, 1904, to March 31, 1905; buildings, £2,010; machinery, £5,240; the remaining 10 per cent. on the Ferranti set, £335; additional transformers, £100; concentric cable for reserve, £25; and cable for Prince of Wales's Pier, bridge, etc., £450. The other items were: £2,000 cost of mortgage (the bill for which was being taxed at the Local Government Board's request); £1,500 for free wiring; and £2,000 for meters; accounting in all for a total of £24,508 expenditure in respect of the loan of £24,475.

Digitized by Google

Felixstowe.—The Urban District Council have completed the purchase of the Suffolk Electricity Supply Company's works at Felixstowe. The company will still carry on the undertaking, under the Council, for the next 25 years, when the Council will take over the entire control without payment to the company. In the meantime the company are to receive all the profits and pay the Council 6 per cent. for all capital moneys advanced. This is in payment of interest and sinking fund on the loans borrowed by the Council for the purpose of the purchase, and all additional new works. The purchase price is £8,000, of which £5,000 was paid on Friday. The remaining £3,000 is retained until the company can show that the undertaking is paying 6 per cent. The price of the current is to be reduced from 8d. to 6½d. per unit, but this will be increased to 8d. per unit during the three summer months, when it is reckoned the visitors will defray the extra cost. The Council are thus relieved of all responsibility in the working of the plant, and the company become lessees of the works, and pay to the Council in the nature of rent 6 per cent. of the capital expenditure, which will pay both the interest on the purchase money and the sinking fund, so that in 25 years the Council will take over the works practically free of cost, without any payment for goodwill or compensation for loss of future profits. The purchase was completed at the Felixstowe Town Hall on Friday morning, between Mr. J. Manning Prentice, the solicitor to the company, and Mr. F. B. Jennings, clerk to the Council. A move was afterwards made to the electric light works, where the undertaking was formally handed over to the Council by Mr. P. C. N. Peddar, the chairman of the company, nailing a brass plate, bearing the Council's name, to the entrance to the works. The engineer to the company (Mr. Napier Prentice), the Council's engineer (Mr. R. P. Wilson), and Mr. C. F. Fisk (chairman of the Lighting Committee) were amongst those present.

PROVISIONAL PATENTS, 1904.

Nov. 7.

23991. Improvements in magnetic suspensions for the moving parts of measuring instruments. Allgemeine Elektricitäts-Gesellschaft, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Nov. 6, 1903, being date of application in Germany.) (Complete specification.)

24030. An improved electric time switch or contactor. Frederick William Edmund Jones, 17, Claremont-road, Leamington.

24065. Improvements in electric switches. Louis Thurnauer and Alexandre D'Oreli, 4, South-street, Finsbury, London.

24078. Manufacture of single or multiple electric conductors. Société Industrielle des Téléphones, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, March 11, 1904, being date of application in France.) (Complete specification.)

24089. Improvements in or relating to electric motors and controlling devices for use in the electrical propulsion of vehicles. John Smith Raworth, 46, Lincoln's-inn-fields, London.

24093. An improved receiver for use in wireless telegraphy. John Greeme Balsillie, Clun House, Surrey-street, Strand, London.

Nov. 8.

24101. Improvements in automatic machinery for winding wires, cords, electric cables, and the like. Alexander Douglas Barty, Moss Works, Prescot, Lancs.

24102. Improvements in mountings and connections for electrical conductors, especially applicable to the supports for collecting brushes of dynamo-electric machines. The Phœnix Dynamo Manufacturing Company, Limited, Wilhelm Oelschläger, and Fredrick Haddock, 322, High Holborn, London. (Complete specification.)

24142. Improvement in electric interrupters for high-frequency currents. George Ephraim Johnson, 65, Chancery-lane, London. (Complete specification.)

24145. An improved thermometer to be used with electricity and in conjunction with various apparatus. Benjamin Foster Wickens, 10, Cranbrook-park, Ilford, Essex.

24166. Improvements relating to electric accumulators. Francois Mouterde, 7, Southampton-buildings, Chancery-lane, London.

24177. Improvements in thermo-electric batteries. James Yate Johnson, 47, Lincoln's-inn-fields, London. (A. Wolf, jun., and Co., Germany.)

24178. Improvements in the manufacture of thermo-electric batteries. James Yate Johnson, 47, Lincoln's-inn-fields, London. (A. Wolf, jun., and Co., Germany.)

24180. Improvements in and relating to protective devices for electric transmission systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24181. Improvements in systems of electric distribution. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24190. Improvements in alternating-current motors, also relating to generators and direct-current machines. Valere Alfred Fynn, 70, Chancery-lane, London.

24192. Improvements relating to electric telegraphy. Sidney George Brown, 7, Southampton-buildings, Chancery-lane, London.

24200. Improvements in electric switches. Percy Lemon Clark, 18, Buckingham-street, Strand, London. (Complete specification.)

Nov. 9.

24225. Improvements in wheel guards and obstruction removers for electric tramcars or other electrically-driven vehicles. Eric Nicholson, Canal Bank, Carlisle.

24276. Improvements in alternating-current motors. Valere Alfred Fynn, 70, Chancery-lane, London.

Nov. 10.

24310. Improvements in lighting by means of Nernst electric lamps or the like. George Wilkinson, Beech Mount, Otley-road, Harrogate.

24316. Improvements in electric arc lamps. August Eckstein and Arthur Ernest Angold, Peel Works, Adelphi, Salford, Manchester.

24323. Improvements in and relating to electric traction. Joseph Birkbeck, Sunbridge-chambers, Bradford.

24341. Improvements in electric switches. Owen David Lucas, 39, Victoria-street, Westminster, London.

24342. An improvement in carbons for electric arc lamps. Frederick James Green, 96, Brookbank-road, Lewisham, London.

24343. Improvements in electric signs. Julius Heinemann, 55, Chancery-lane, London. (Complete specification.)

24351. Improvements relating to dynamos and other rotary electric machines. Miles Walker, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London.

24358. Improvements in carbon-feeding mechanism for electric arc lamps. Gregory Douglas Mantle, 9, Regent-street, London.

24369. Improved arrangement of electric emergency lamps in theatres and like buildings. Fritz Brandt, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24379. Improved means for use in connection with electric motors and centrifugal separators or other apparatus driven by such motors. William Harding Scott and Robert Williamson, 47, Lincoln's-inn-fields, London.

24384. A combined mouth gag and electric light. John Sides Davies MacCormac and the Dental Manufacturing Company, Limited, 322, High Holborn, London.

24388. Improvements in electric circuit breakers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24389. Improvements in controlling devices for electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24390. Improvements in insulators for the live rails of electric railways, tramways, and the like. Oswald Erlands, 18, Buckingham-street, Strand, London.

24394. Improvements in means for connecting electric circuits, especially applicable for the lamps of motorcars. Dominique Couverchel, 1, Queen Victoria-street, London. (Date applied for under Patents Act, 1901, Dec. 19, 1903, being date of application in France). (Complete specification.)

Nov. 11.

24399. Improvements in electric tools. Paul Schiemann, 37, West Nile-street, Glasgow. (Complete specification.)

24423. Improvements in electricity meters. Chamberlain and Hookham, Limited, and Sydney Holmwood Holden, 4, New Bartholomew-street, Birmingham.

24429. Improvements in telephone systems. William Aitken, Milton-road, Edge-lane, Liverpool.

24432. Improvements in or relating to electro-mechanical synchronisation apparatus. Bahne Bannikaen, 18, Hertford-street, Coventry.

24443. An improved multiple-filament incandescent lamp. Joseph Klopfenstein, 11, Southampton-buildings, Chancery-lane, London.

24464. Improvements in and connected with the field windings of series-wound dynamo-electric machinery. Arnold Frank Hills, David Urquhart, and Alfred Edward Honey, 4, South-street, Finsbury, London.

24466. Improvements in electrical conductors. Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

24470. Improvements relating to electric, gas, or vapour apparatus. Peter Cooper Hewitt, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Nov. 24, 1903, being date of application in United States.) (Complete specification.)

24477. Improvements in or connected with electric arc lamps. Frank Michael Lewis, George William Lewis Case, and the Beason Manufacturing Company, Limited, Norfolk House, Norfolk-street, Strand, London.

24485. Improvements in electric meters. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Nov. 12.

24538. Improvements in electrical fuses. Bertram Thomas and Gustave Thomas, Worsley-street, Hulme, Manchester.

Digitized by Google

24539. Improvements in automatic electric switches or circuit breakers. Bertram Thomas and Gustave Thomas, Worsley-street, Hulme, Manchester.

24560. Electric testing clip. Harry Frankel, 321, High Holborn, London. (Date applied for under Patents Act, 1901, Dec. 2, 1903, being date of application in United States.) (Complete specification.)

24569. Improvements relating to the supply of current to electric vehicles. Oscar Howard Baldwin, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London.

24572. Improvements in connection with electric igniters for internal-combustion engines The Marquis Albert de Dion and Georges Bouton, 47, Lincoln's inn-fields, London. (Date applied for under Patents Act, 1901, Aug. 16, 1904, being date of application in France.) (Complete specification.)

24573. Improvements in dynamo-electric machines Asa Fred Batchelder, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Nov. 12, 1903, being date of application in United States.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED

To be published Dec. 1, 1904.

1903.

23853. Mercury electrolytic apparatus, specially applicable to electric meters and electric switches. Du Bois and Reason Manufacturing Company, Limited.

24063. Electrical apparatus used in propelling autocars and other vehicles, launches, and the like. Rees.

24235. Electric arc lamps. Davy.

24701. Multiplication of electric force, applicable to machinery of all kinds requiring power. Howell.

25322. Electrical resistances Matthews and Hoghton.

26856. Electric circuit-breaker mechanism. Crompton and Co., Limited, and Harris.

26954. Mechanical device applied to the cars or cages of electrically-driven lifts and belt-driven lifts. Moffatt.

27069. Means or apparatus for operating points on electric tramways, light electric railways, and the like. Cardell.

28607. Electrical fuse holders, fuse boxes, and the like. Baily.

1904.

319. Electric cables. Field.

330. Electric fuses. Lackie and Callerwood.

351. Safety device for use on vehicles propelled by electric traction on the stud contact system. Griffiths and Bedell.

1006. Spark-extinguishing apparatus for use in connection with electrical high-frequency circuits. D'Arsonval.

2347. Composition for electrical conduits. Starke.

2512. Electrical joint-boxes. Groves.

4062. Electric arc lamp. Scialpi.

14523. Telephone systems. Fairweather. (American Electric Telephone Company.)

15869. Installations for electrically operating railway points. Siemens Bros. and Co., Limited. (Siemens und Halske Act.-Ges.)

16871. Receiving telegraph instrument. Underhill.

17166. Chain for suspending electroliers. Clements.

18919. Terminal or coupling for electric cables. Middleton and Middleton.

18991. Systems of electrical distribution. Thomas. (Date applied for under International Convention, Sept. 4, 1903.)

19265. Electrical fire-alarms. Hoenicke.

20001. Systems of electrical distribution. Lincoln. (Date applied for under International Convention, Sept. 30, 1903.)

20165. Electrical signalling apparatus for fire calls and the like. Pinching and Walton.

20864. Wireless telegraphy systems. Thompson. (Gesellschaft für Drahtlose Telegraphie m. b. H.)

21648. Trolley heads employed in electrical traction. James and West.

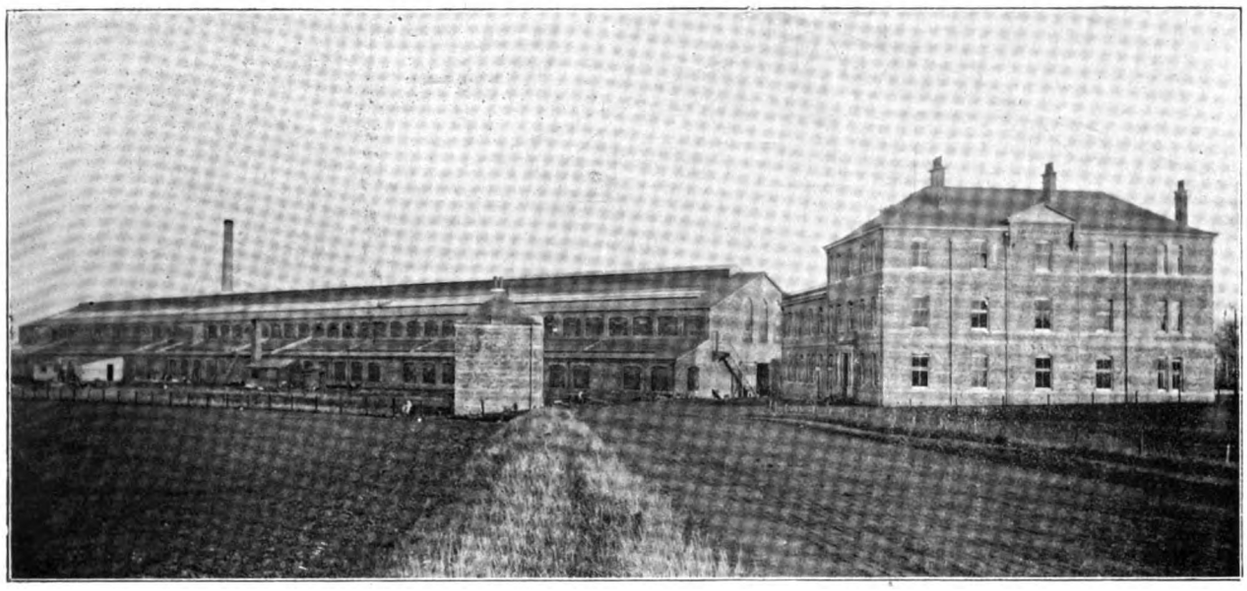
MESSRS. BRUCE PEEBLES AND CO.'S NEW WORKS AT EAST PILTON, EDINBURGH.

The firm of Messrs. Bruce Peebles and Co. have been well known in engineering circles for a very long time, and they have had a reputation for good work from the first.



Messrs. Bruce Peebles and Co.'s New Works and Offices at East Pilton, Edinburgh.

When the firm decided to launch out into the electrical side of engineering they secured the services of Mr. Roland S. Portheim and Mr. M. T. Pickstone, which accounts for the three P's in their trade mark. This departure was made only eight years ago, but owing to the excellent design and the consequent good performance of the generators and motors manufactured by the firm, the growth of the business has been exceedingly rapid. The electrical business soon outstripped the other departments of the firm, and the old Tay Works became too small to cope with the orders obtained. It speaks well for the heads of the firm that this rapid growth of business has been concurrent with a time of very severe competition, first from American and Continental firms, and latterly from other manufacturers within the United Kingdom. In 1903 the business was found to have altogether outgrown the capacity of the Tay Works at Leith, and, in consequence, the works we are now about to describe were erected. It might be well at the outset to give a general idea of the type of work which the firm are now undertaking, and hence the following reference to contracts in hand will be of service. The volume of work comprised in these and other contracts is such that already the manufacturing facilities of the East Pilton works are severely strained, and extensions are contemplated as indicated in the block plan (Fig. 1).

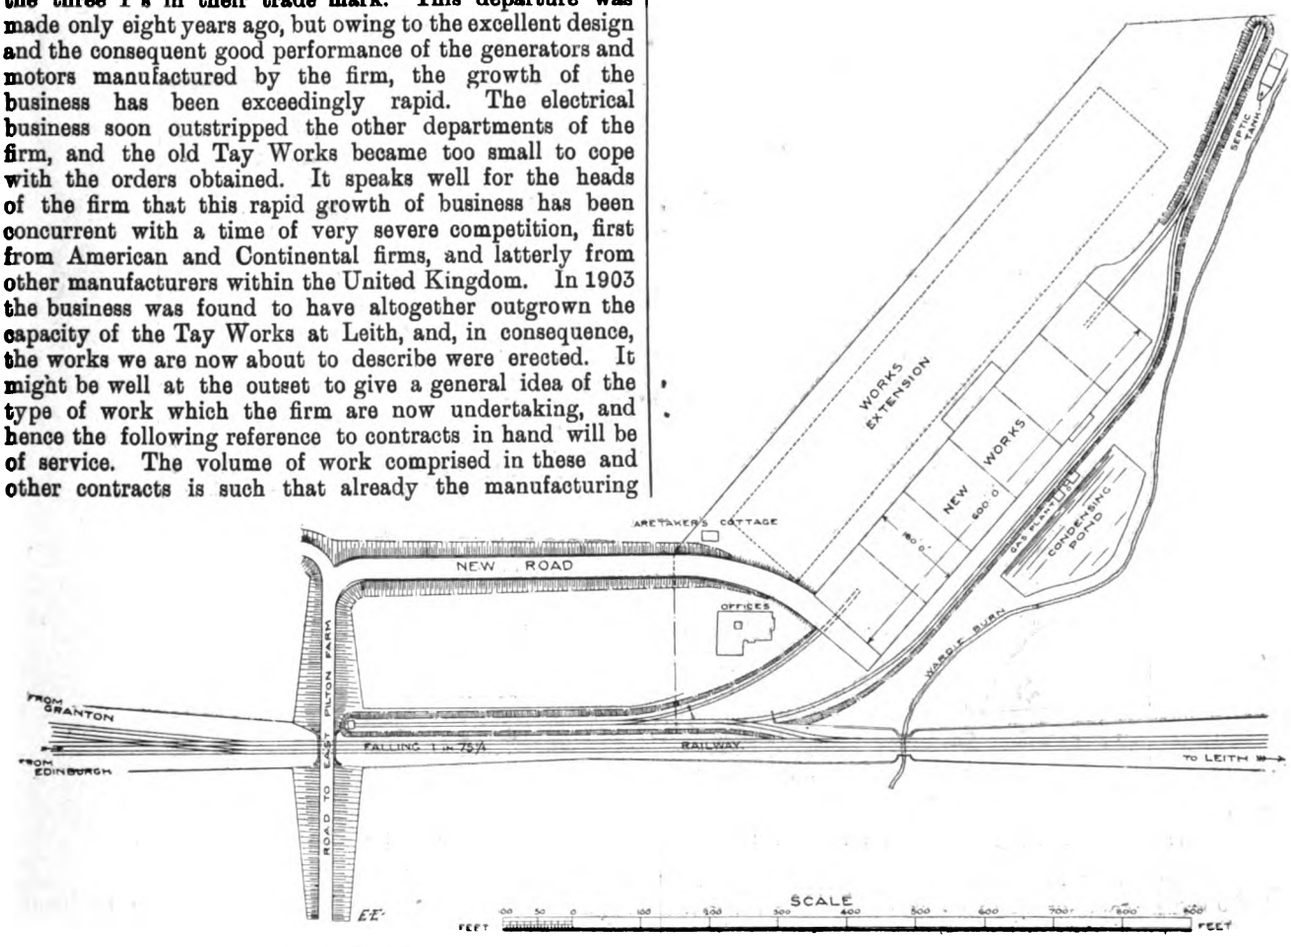


FIG. 1.—Block Plan of Messrs. Bruce Peebles and Co.'s New Works at East Pilton, Edinburgh.

On going through the shops one is struck by the exceedingly large number of machines, varying in output from 1,500 kw. to 500 kw., in hand for contracts of every description. Standing opposite one of the boring machines, we noticed a stator of one of four 1,500-kw. machines at 10,000 volts being machined. These were for the North Wales Electric Power Company. This company is now just completing a hydro-electric power station at Portmadoc with a capacity of some 10,000 h.p. to the joint designs of Sir Douglas Fox and Messrs. Harper Bros, the consulting engineers. The water supply is drawn from Loch Llydaw, on the lower summit of Snowdon, with 1,200ft. head. Turbines of the Pelton type drive the Peebles alternators now going through the shops in 1,500-kw. units, giving 10,000 volts, three-phase. The current is utilised for two turbines, one for driving a three-phase electric railway 18 miles in length, parts of

Digitized by Google

the locomotives of which, at 250 h.p. capacity, are now being manufactured at East Pilton. Owing to the narrow gauge of the line, and the high power of the motors, these are placed with vertical axles, and drive by bevel gearing. This electric railway will be three-phase throughout, and as the railway feeders supply the quarries on the line of route, the advantage of one system for both purposes is obvious.

a commutator at the other, the construction being exceedingly simple and efficacious.

In the left bay in the motor assembling room we saw over 100 Peebles tramway motors in various stages of construction, some 60 of these being required for the Sunderland and District Power Company, the whole contract for the electrical machinery of which has been manufactured by

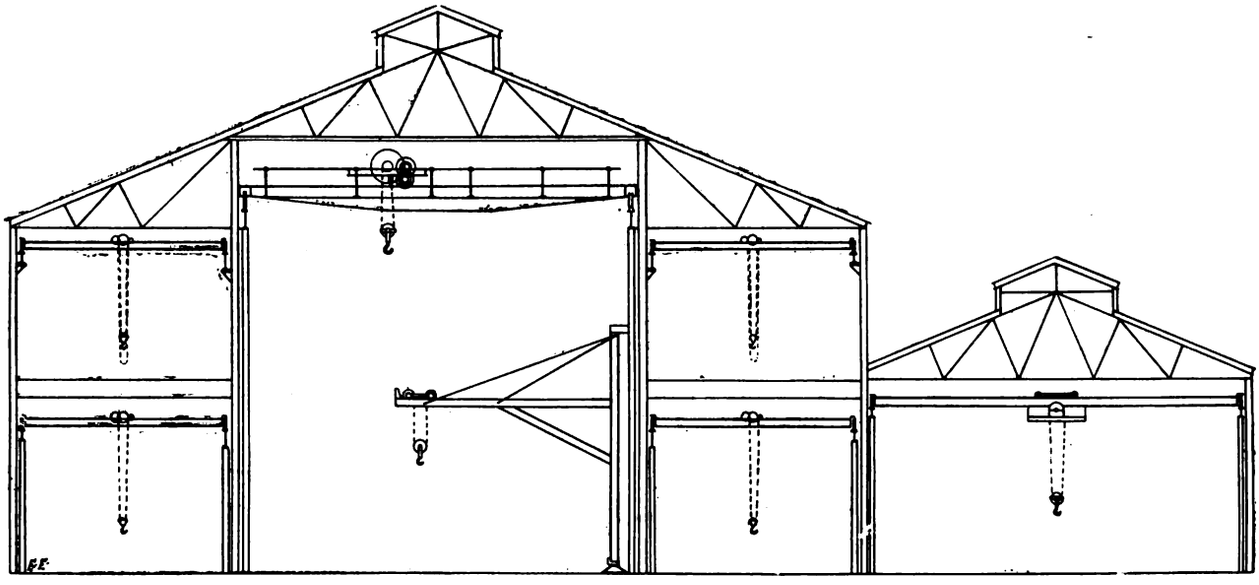

FIG. 2.—Section of the Works, showing Cranes and Lighting facilities.

A little further on we came to two 500-h.p. three-phase generators which were being built by Messrs. Bruce Peebles and Co. for the Canadian Electric Traction Company. This three-phase railway scheme involves some 30 miles of track, commencing at the city of London in the Province of Ontario, Canado, running from there to Port Stanley on Lake Erie. The initial power-house, which is being

Bruce Peebles and Co., Limited, including 1,000-h.p. gas-driven generating station. Amongst some of the other larger machines were two 600 h.p. three-phase alternators for the Fife electric power station, being the first portion of a 2,500-h.p. generating plant contract, the whole of which, including boilers, switchboards, etc., is in the hands of Bruce Peebles and Co.

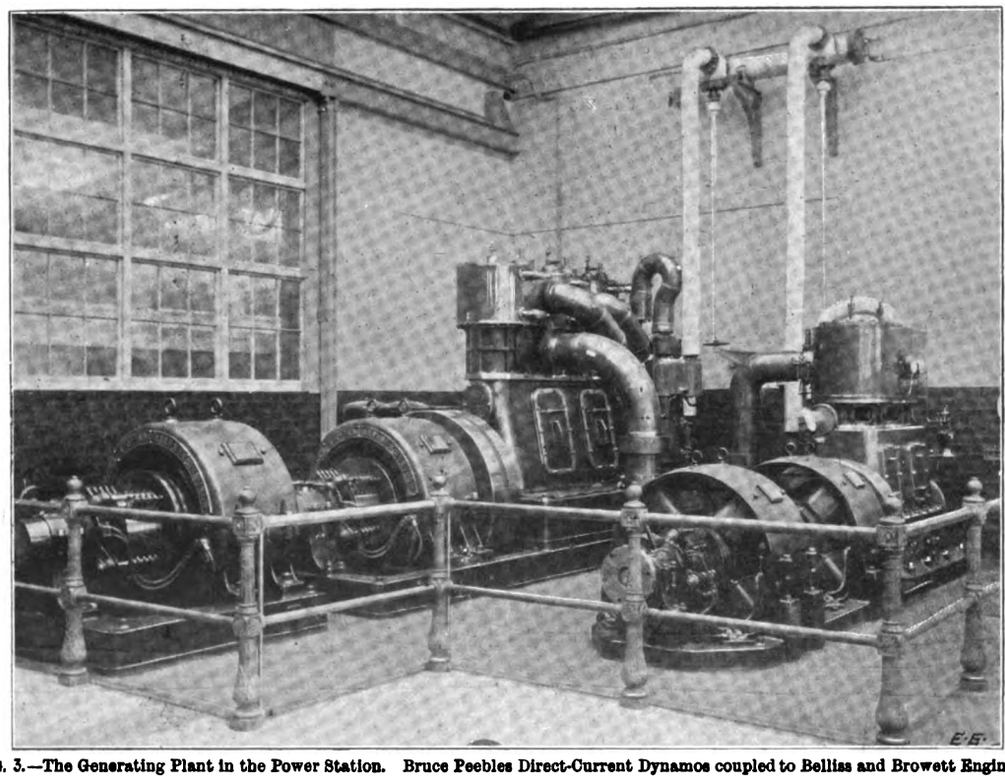

FIG. 3.—The Generating Plant in the Power Station. Bruce Peebles Direct-Current Dynamos coupled to Bellias and Browett Engines.

constructed by Messrs. Bruce Peebles and Co. in Canada, is of 1,000 h p. capacity, and the motors of the firm's manufacture are of an exceedingly interesting design, being combined continuous current and three-phase, so that the same motor when running between the towns and the open country runs as a 1,000-volt three-phase motor, and when running through the towns on the existing 500-volt continuous-current system runs as an ordinary series traction motor, the rotor having slip-rings at one end and

Parts of similar machinery for a similar installation—the Scottish Central Power Company—were also in hand. This latter power station is about to supply power to the Falkirk and District Tramways Company, the contract for the whole of same, including permanent way, now being constructed by the firm, whose traction department, to judge by the orders on hand and orders going through, seemed full to overflowing. In the continuous-current department we saw parts of six 750-kw. direct-current

Digitized by Google

machines for H.M. Dockyard, Chatham, in various stages of manufacture, together with a large number of motors.

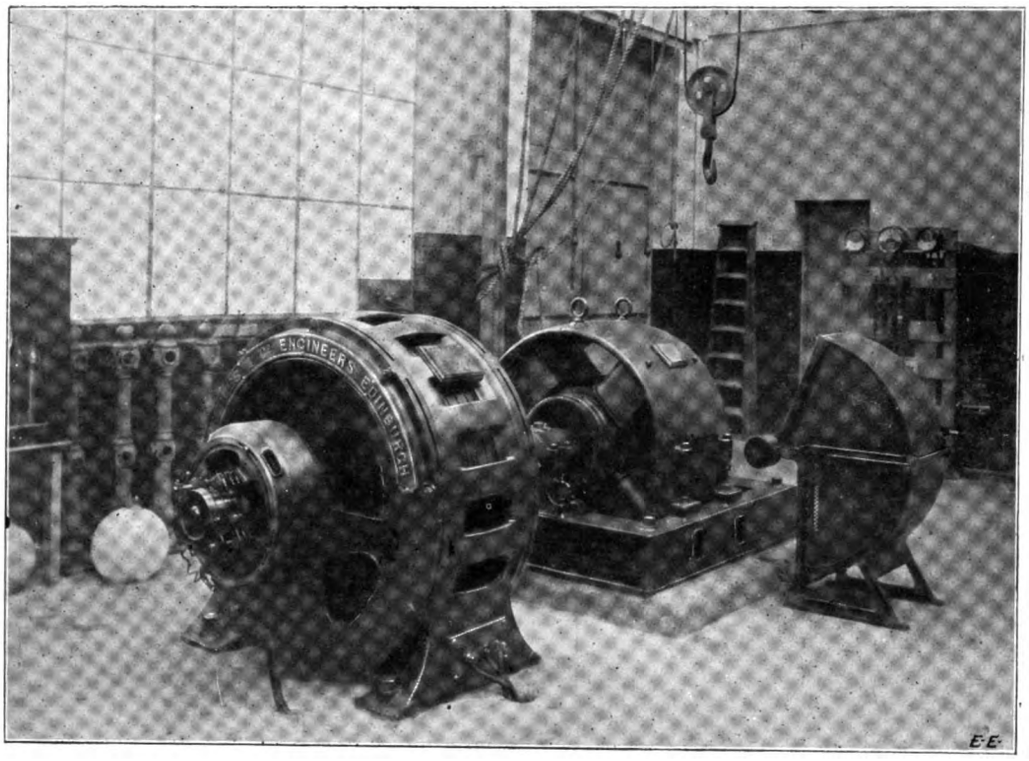

FIG. 4.—The Motor-Generators in the Power Station.

We understand that the whole of the contract for this important dockyard is in the hands of the firm.

On the heavy end of the test plate were two sets of

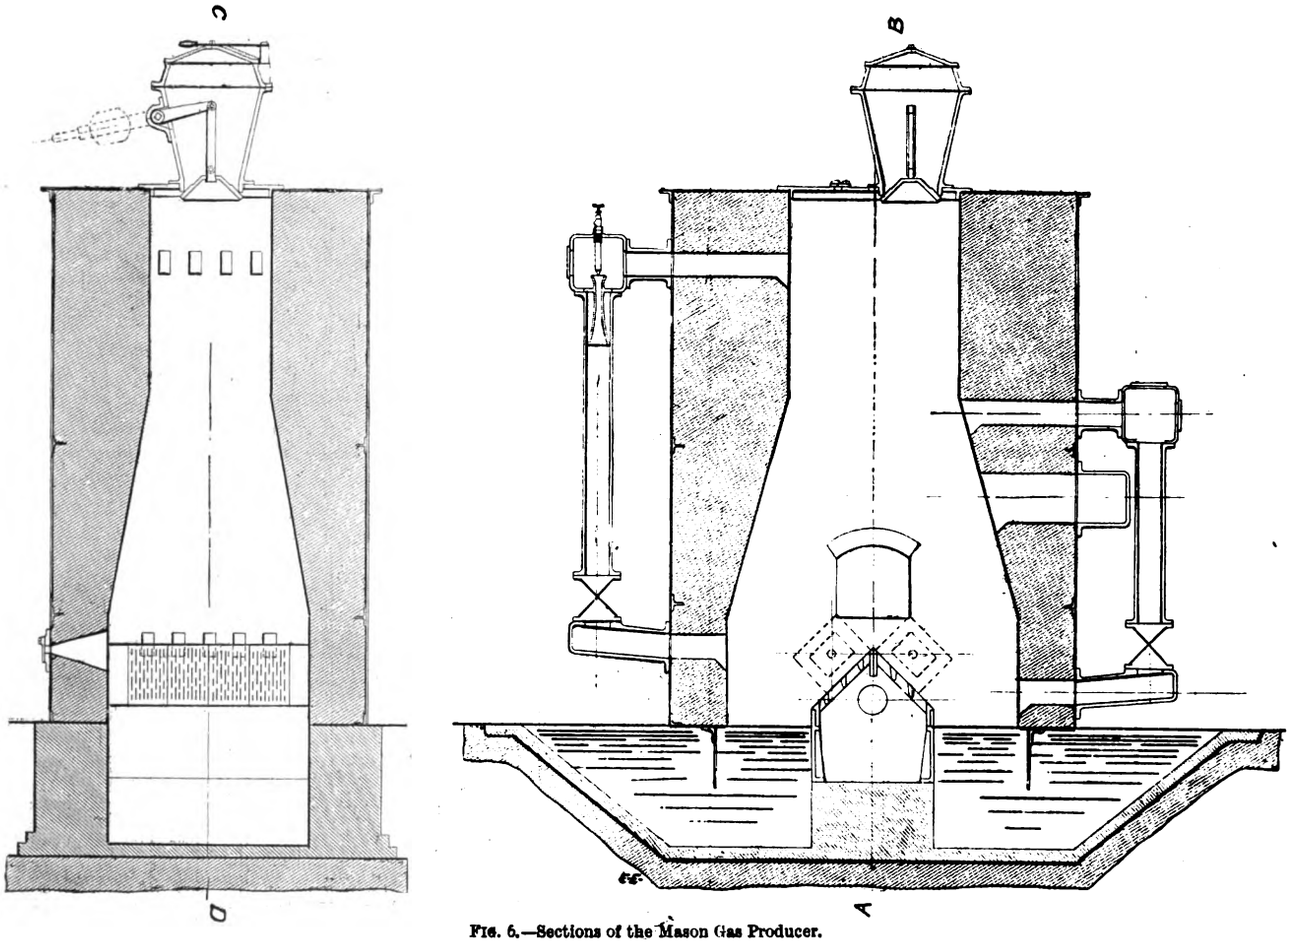

FIG. 6.—Sections of the Mason Gas Producer.

500-kw. motor-generators going through for the Poplar Corporation, being part of an order of six for this Corporation on the Peebles-La Cour system, which exceedingly interesting example of improved motor-generators we shall have to describe in detail later on. The Peebles-La Cour motor converter is really a rotary with all the advantages of a motor-generator, and the best tribute to this system is the fact that over 20,000 kw. of this particular type are now on order, including 8,000 kw. for the Great Western Railway Company. The orders which are now being placed for these motor-generators fully justifies the firm in their adoption of the system, and they are further to be congratulated in having secured the services of Mr. La

Cour himself as head of the electrical designing department. In the space at our disposal it is impossible to describe

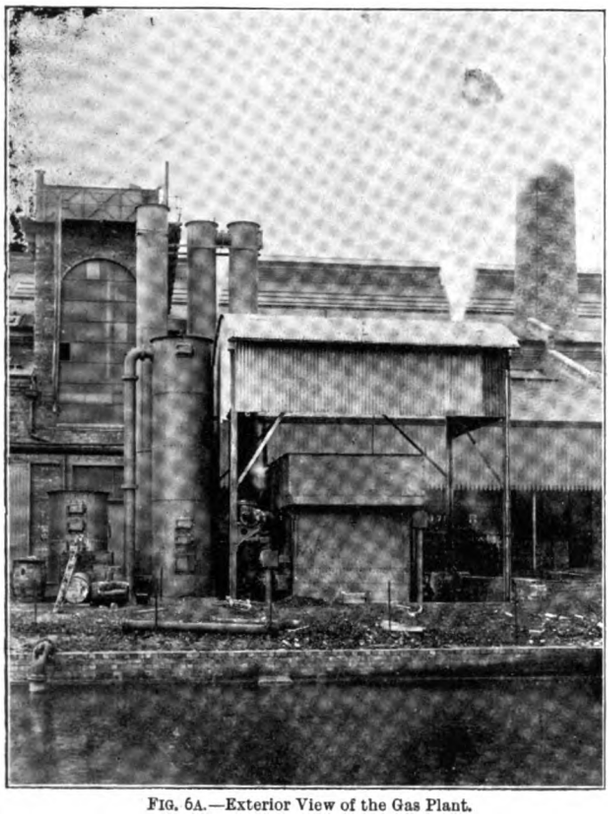

FIG. 6A.—Exterior View of the Gas Plant.

the enormous amount of shipbuilding and colliery equipment work which Bruce Peebles and Co. are doing. Suffice to say that some of the most important collieries and shipping firms appear to be customers on a very large scale, judging from the stencilled names we saw on the machines being tested and dispatched.

The East Pilton works are situated on a site overlooking the Firth of Tay and adjoining the Leith branch of the Caledonian Railway. The site is shown in the block plan (Fig. 1), on which the siding facilities are clearly drawn. This connection to the railway is a most valuable one, as it gives easy access not only to the railways of the country, but also to the docks at Glasgow and Leith. The works stand in open country in a most healthy situation, and are arranged so that they can be conveniently extended. There is much to gain from choosing a position, as Messrs. Bruce Peebles and Co. have done, outside a large town: the employés have all the advantages of the town, and the manufacturers are not a nuisance in any way to those living in their immediate vicinity, as may be the case if they were in the town itself. It will be seen from the block plan that the offices are placed in a separate building. The drawing offices are situated in the galleries of the new works. The main machine-shop is 600ft. long by 160ft. wide. It will be seen that there is railway access to either end of this long building, and, as will be explained later, the raw materials and castings are brought in at the end of the works nearest the offices, while the finished machinery is dispatched on the line leaving the works at the farther end. There is thus a constant forward movement of the parts towards the packing-room at this end. The arrangements within the works for transporting the materials and machinery are most ample, as will be gathered from the section of the works (Fig. 2). In this illustration, which is not quite a true section, there is shown no less than six travelling cranes. These do not all, however, run the full length of the factory. The following details of these travelling and other cranes will be of interest. Thus the main shop is spanned by two 15 ton travelling cranes, each with two-speed gear and three motors. The speeds of motion are as follows: heavy lift, 12ft. per minute; lift up to six tons, 24ft. per minute; travel 300ft. per minute; traverse, 80ft. per minute. The motors for

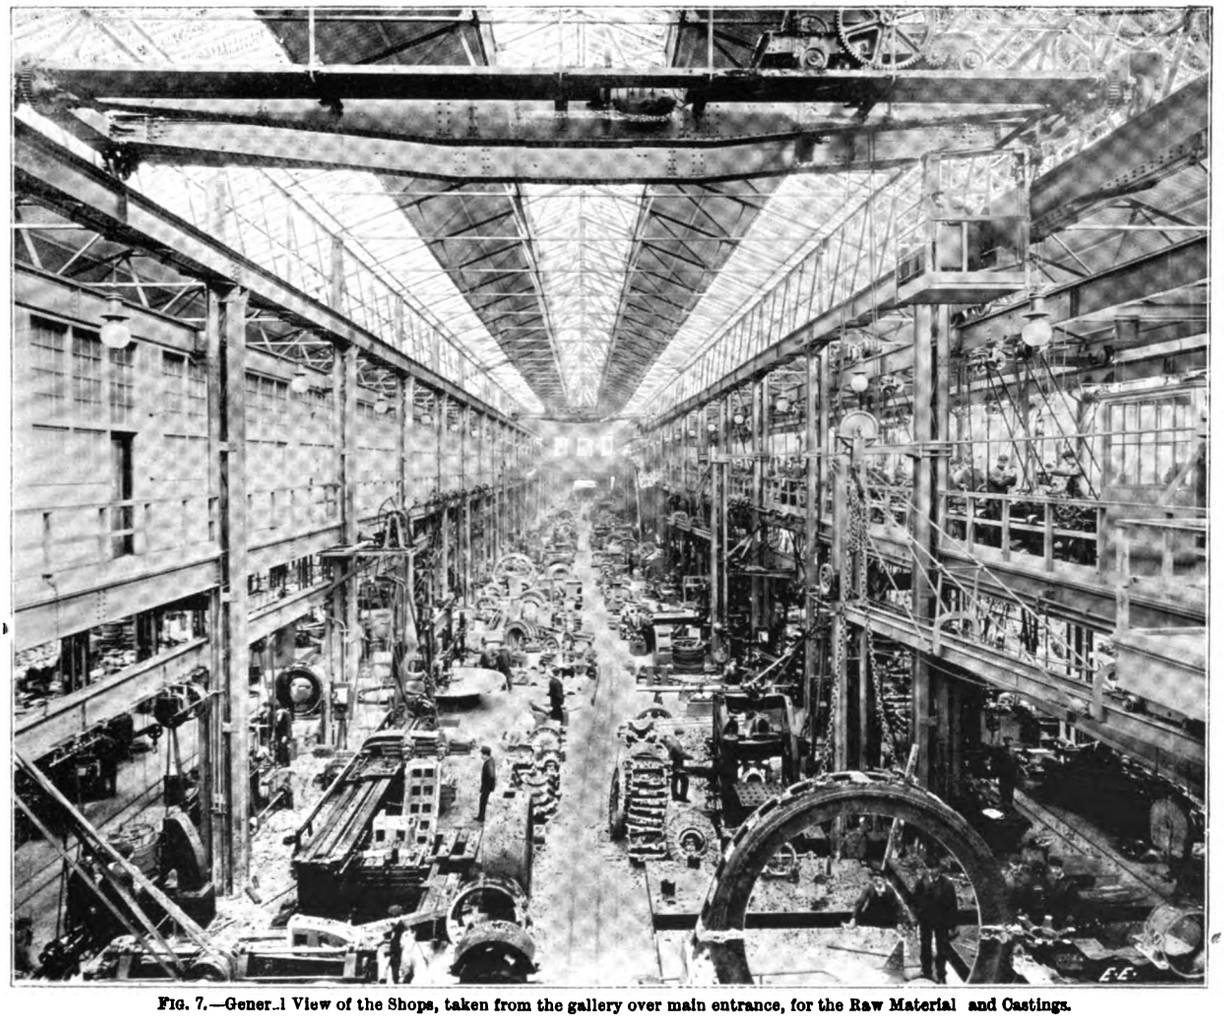

FIG. 7.—General View of the Shops, taken from the gallery over main entrance, for the Raw Material and Castings.

Digitized by Google

the lift are of 15 b.h.p., for the travelling motion 10 b.h.p., and for the traverse 3 b h.p. In the side bays are found two six-ton cranes with similar speeds for travel and traverse, and equipped with motors of 7 h.p. and 2 h.p. for these respective motions. A lift motor of 12 h.p. is fitted in each case, and six-ton loads can be raised at 20ft. per minute and three-ton loads at 40ft. per minute. The span of these cranes is 24ft. There is also a six-ton electrical crane in the light erecting shop. This, however, differs from the other six-ton cranes in having one motor only, and being worked from the floor level instead of having an operator in a cage. One motor drives the various motions by means of belts and ordinary striking-in gear. In addition to the above, there is a five-ton two-motor crane and a large number of two-ton one-motor travelling cranes. An interesting feature of the main shop and the light erecting shop is the number of two-ton jib cranes in use, as will be seen from the general arrangement drawing. These jibs have a very wide span, and are found extremely useful for handling work being set up on the tools, etc.

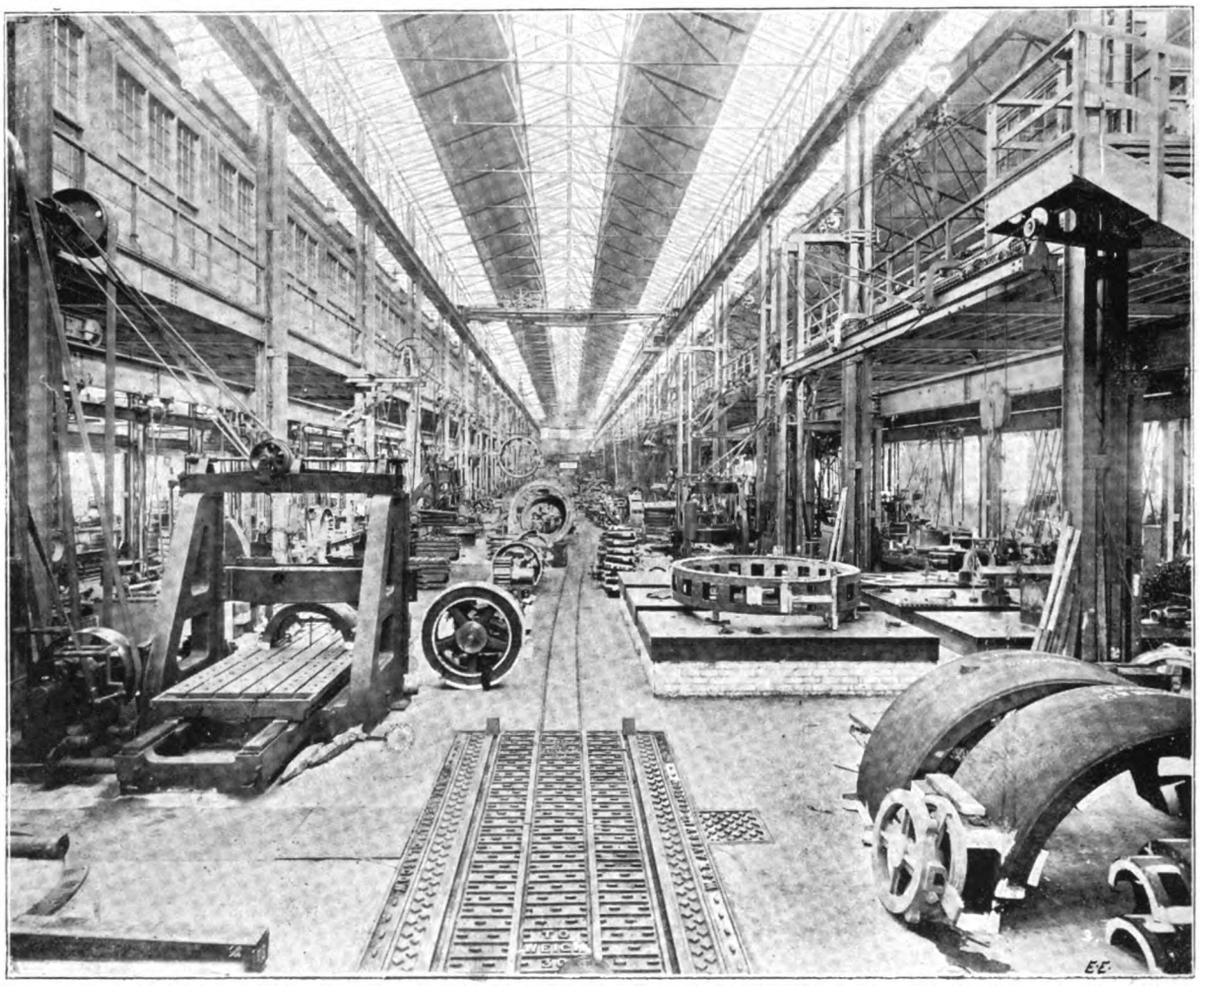

FIG. 8.—General View of the Shops from ground level at main entrance. The marking off for Surface Plants are seen on the right and the Large Planer on the left.

POWER SUPPLY.

Before proceeding with the arrangement of the various departments in the works, a few words as to the power plant will be of interest. Messrs. Bruce Peebles and Co. have naturally adopted electrical driving throughout, and they have also wisely introduced a considerable variety in the method of applying electricity. This enables them to show to their customers various systems at work, and also to demonstrate the fact that there are distinctive advantages in each of these systems. Thus in the power station they have two main generating units. The largest set (seen in Fig. 3) consists of a high-speed engine made by Messrs. Belliss and Morcom, driving two dynamos of the firm's own manufacture. Each of these is able to give 750 amperes at 250 volts. The smaller steam set seen in the right of Fig. 3 consists of a Browett and Lindley engine coupled to two Bruce Peebles dynamos, each capable of giving 320 amperes at 250 volts. These two generating sets supply the bulk of the power and light required in the factory, on the three-wire system, with 230 volts between the middle wire and either of the outer. All the lighting is done at 230 volts, and the motor supply is either at this voltage or at 460. In certain cases where speed regulation over a wide range is required, the voltage on the motor armature is altered from 230 to 460, or *vice versâ*, as may be required to give the speeds needed. This refers to the direct-current supply only, and with this system there is also a great variation in the application of the motors to the work. Thus the larger machines have each their own motor. When smaller tools have to be driven, a number are connected by belting on to a common countershaft. This countershaft is in turn driven by a single motor, either through gearing or by means of a belt. In the galleries these countershafts are placed on pedestals behind the machine tools, and hence are on the ground-level, where they are easy of access. It is thus only the special countershaft for each tool with the cones for speed changing which are overhead, and the result is remarkably good, as it leaves a clear way for the overhead traveller. There is also in the power station a motor-generator (Fig. 4) which converts electrical energy from direct current into three-phase currents at 50 frequency. The output of this machine is 120 kilovolt-amperes at 240 volts. From the three-phase side of this converter a number of induction motors are supplied. These motors are mostly used for driving the tools in the galleries, where a number of machines are grouped together under the one countershaft.

The steam for these generating sets is obtained from the boiler-room adjoining, the position of which can be seen in Fig. 5. Two boilers have been installed, one being of the Stirling water-tube type, doing 418 h.p at 220lb per square inch working pressure; the heating surface of 1,305 square feet, giving an evaporation of 8,360lb. of steam per hour. The other boiler is of the Babcock and Wilcox type, having 1,426 square feet of heating surface and giving an evapora-

Digitized by Google

tion of 5,200lb. per hour. The condensing plant is by Messrs. Blake-Knowles of the cast-iron coil type, capable of condensing 5,000lb. per hour at a vacuum of 27in.

Adjoining the boiler-room, but quite independent from it, is the gas-producer plant, which may well be classed with the other machinery in the power department. This producer plant has been recently installed by Messrs W F. Mason, Limited, of Manchester, under the Luff and Whitfield patent. As this plant is of a novel type, we reproduce a section of the producer (Fig 6) showing its characteristics. The principal feature of this type of producer is that by the peculiar construction of the generator and grate the amount of tarry matter carried over with the gas is reduced to a minimum. The exterior casing of the generator is rectangular, and built up of steel plates stiffened with T irons, the interior being completely lined with firebrick. The bottom of the casing dips into a trough filled with water, which forms a gastight seal and serves to quench the ashes, so that these may be removed while the plant is working, and that continuous operation presents no difficulties. It will be seen that the grate is now formed of two inclined surfaces, meeting in a ridge running lengthwise of the producer. The grate is perforated with slots, through which air, forced into the interior space, rises through the fuel. Gas leaves the generator from about the centre of its height, passing up flues on each side and reuniting in the brick-lined main, at the end of which is situated the main outlet valve. Near the top of the producer on each side there are orifices connected by down pipes with similar orifices immediately beneath them on a level with the centre of the fire-grate. On the down pipes is fixed a small steam jet, pointing downwards into the neck of an expanding nozzle. These jets exhaust the tarry vapours distilled from the upper layers of the coal, and drive them, mixed with steam, back into the incandescent fuel in the lower part of the furnace. The steam is here dissociated, the oxygen combining partly with the tarry vapour and partly with the hydrogen, and then passing up through the fuel to the main outlet. Thus hydrogen and carbonic oxide are formed comparatively pure and undiluted with nitrogen. The arrangement of the coolers and the coke and sawdust scrubbers presents no unusual features. The top of the gas generator is fenced round to form a firing platform, from which the attendant feeds the furnace. Under ordinary working conditions the cooler-boiler, through which the gas passes direct from the producer, raises sufficient steam from the waste heat of the gas to supply the needs of the plant itself. The gas is used in Messrs. Bruce Peebles's works for heating the annealing oven and the drying-out oven; the latter is maintained at a temperature of about 180deg. night and day, the gas being employed to heat the floor, and not coming in contact with the machinery being dried in the oven at all. The annealing oven is constructed under the same principle, the heating being done in air only in each case. The large drying-out oven, which is shown next to the varnish shop on the general plan, measures 40ft. by 25ft., and is a most successful adjunct to the equipment. In the pump-house, between the boiler-room and engine-room, there are also placed the hydraulic and pneumatic pumping plants. The hydraulic plant was supplied by Messrs. Mactaggart, Scott, and Co., and is utilised for driving five hydraulic lifts and nine two-ton jib cranes. The working pressure is 1,200lb. per square inch, and the accumulator, which measures 14ft. by 8ft. with a lift of 10ft., is supplied by a set of three-throw motor-driven pumps. The pneumatic plant consists of two air-compressing engines and an air receiver, measuring 9ft. by 3ft. The plant is mainly used for supplying chippers and drills, portable hammers, etc., and also for drawing water from a well 450ft. deep to an elevated tank at the rate of 1,800 gallons per hour.

FIG. 9. - Building up the Stator Core of one of the Pumpherston Generators, to give 670 K.V.A. at 300 revolutions per minute.

We propose now to deal with the general arrangement of the plant and to give a few descriptive notes of the work, following through the same order as the various materials from the time they enter until they leave the works as finished machines. Fig. 7 is a general view looking down the main shops from a point on the gallery immediately over the main entrance. Fig. 8 is another view taken in the entrance itself, showing the weighbridge on which the siding from the Caledonian Railway terminates. On the right are seen the large surface plates, each 12ft. by 6ft., on which the castings are marked off. In order to deal with the very largest castings there are six of these surface plates, all on the same horizontal plane, with 1ft. gangways between for the men engaged in the important work of marking off. On the left, opposite these marking-out beds, is a large planing machine by Messrs. Buckton and Co., of

Digitized by Google

Leeds. This machine will take a job 14ft. by 6ft. by 6ft., and has a return motion two and a half times as fast as the cutting stroke. The cutting speed is 29ft. per minute with a feed of $\frac{1}{16}$in. to $\frac{3}{4}$in. Two holders are fitted. This tool is driven by an individual motor of 20 h.p. On the pulley shaft is a multiple-thread worm driving a skew gear-wheel set at an angle of about 45deg. from the direction of the motion of the bed. The shaft on which this gear-wheel is mounted has a worm cut on it which drives the bed by means of rack cut on the under-surface of the latter. Next to this tool is a large side planing machine by Messrs. Richards. This machine has an 18ft. stroke and a 4 to 1 return speed, the cutting speed being 20ft. per minute. The feed is from $\frac{1}{32}$in. to

NOTES.

New Publications.—"Model Steam-Turbines" by H. H Harrison (London: Percival Marshall and Co. 6d). In the latest addition to the "Model Engineer Series," the author gives the principles on which model steam-turbines may be designed, with several examples.

Birmingham Section.—From a booklet sent us by the Birmingham Local Section, we see that the following dates have been appointed for general meetings: Dec. 14, Jan. 18, Feb. 15, March 15, April 12, and May 10 (annual general meeting). The session was opened on Wednesday, when Dr. W. E. Sumpner, the chairman, delivered his inaugural address. The meetings will be held in the physical theatre of the university. Visits to places of engineering interest have also been arranged. The membership of all grades showed an increase of 59 last session.

The McMillan Memorial Fund.—The committee appointed to receive contributions towards the above have now decided to close the fund on Dec. 1 next. The sum collected now amounts to about £1,760, and any members who intend still to contribute would greatly oblige by sending in their remittances to the secretary of the Institution before the expiration of the present month. We trust that this final reminder will induce those who have neglected to contribute to this fund until now to send in their contributions promptly, and we hope that even yet the expected sum of £2,000 may be secured.

Personal.—We have referred in our columns before to the fact that Mr. A. S. Giles, who for many years has controlled the electric lighting and tramway undertakings of Blackburn, is about to leave England in order to take up an important position in Cape Town. Last week Mr. Giles was presented with a silver tea service and tray by the tramway staff. Mr. A. Nuttall, J.P., the vice-chairman of the Electricity and Tramway Committee, made the presentation, and spoke very highly of the good feeling which existed between Mr. Giles and the entire staff. The presentation was suitably acknowledged by Mr. Giles, who said he should feel very much parting from such a number of good friends. He was wished every success as the general manager of the Cape Town tramways.

N-Rays.—The subject of N-rays took a psychical turn last week, when Dr. S. Hooker announced that, as the result of extensive investigations, he had confirmed the theory of previous experimenters that the human body emits N-rays of various hues, from which the character of the individual can be determined. This produced a considerable shower of opinions from scientists, eminent and otherwise. Some ridiculed the idea, others adopted a tolerant attitude, while the psychological fraternity declared that they had been aware of the existence of these colour characteristics for years. Sir William Ramsay stated that he had never detected the rays, but intimated that he was open to conviction. The scepticism that various critics have expressed in regard to the existence of N-rays has prompted M. Blondlot to reply at some length. He emphatically affirms that he can perceive the rays with the greatest certainty. That persons who cannot see the action of the rays on a phosphorescent screen should doubt their presence he considers quite natural, but he recommends them to lean the back and the head against a wall, and then to observe the screen by holding it at a level below that of the eyes, so that a plane through the eyes and middle of the screen makes an angle of 30deg. or more with the horizon.

Compensation Limit.—The Sheffield Corporation have decided by a large majority to withdraw the notice printed on the backs of the tramway tickets limiting liability for accidents to £25. It may be remembered that this step aroused a considerable amount of criticism, and a member of the Corporation, Councillor Muir Wilson, refused to accept a ticket when travelling on the tramways so as to test the legality of the Corporation's action. The councillor was prosecuted for being unable to produce a ticket, and the magistrate convicted, a nominal fine being imposed with a view to taking the opinion of the High Court. This case, however, scarcely went to the heart of the question. The attitude adopted by the Corporation was that as they charged less than the statutory fares, they were entitled to stipulate that their liability for accidents should be limited. If a notice to this effect constituted a contract, anybody who was unwilling to compromise his right to compensation for injuries upon the terms laid down by the tramway undertakers would be debarred from the use of a public service. The limitation seems to us *ultra vires*, and calculated to prejudice the public against the trams. We think, therefore, the Corporation have acted advisedly in not persisting with a dubious course.

Gas-Producer Plant.—Some interesting figures were recently obtained from some expert trials on a Crossley suction gas plant designed for working with common gas coke. The producer in question is to be exported for the Howrah station of the Calcutta electric supply station, where it is to be used to supply gas for one of the Crossley high-speed engines driving a dynamo. The electrical equipment has been manufactured by Messrs. Crompton and Co. The coke used on the trials was obtained from the Manchester Corporation gasworks, and when analysed was found to consist of 15·6 per cent. of ash, 1·3 per cent. of moisture, 1·8 per cent. of volatile matter, and 81·3 per cent. of fixed carbon. It has a calorific value of 12,411 British thermal units per pound. After a six hours' run at full load the following figures were obtained: total fuel consumed, 488lb.; total kilowatt-hours, 368 4; fuel per hour, 81 3lb.; kilowatts per hour, 61·4; fuel per kilowatt-hour, 1·325lb. This is equal to ·92lb. per brake horse-power hour, which is exceedingly good. It must be remembered that this type of suction gas plant can be used in places where the ordinary producer with its steam blast and gasholder could not be employed. The fact that this producer is working with gas coke is also worthy of special note.

Electric Power Costs.—Mr. W. C. Martin, in a lecture recently delivered in Dundee, made some interesting comparisons as to the cost of power supplied by electricity and steam respectively. He stated that for unlimited use the electric supply from Niagara cost to consumers near Niagara £4 per horse-power per annum, to consumers in Buffalo £4. 13s., and to consumers in Montreal (Canada) £17. 14s. In large towns at home, such as Bradford and Glasgow, where the power is charged at the rate of 1d. per unit, the cost of 1 h.p. for a working year of 2,700 hours would be £8. 8s. Mr. Martin then investigated what it costs the average manufacturer in Dundee for steam power as compared with this. He calculated that in rope works with a simple engine it cost £10 6s per horse-power used 2,700 hours per annum. The sum rose to £13. 2s. for an engineering shop, and to £37 for a small steam plant. In the mills with large modern engines and boilers the cost of steam will naturally be less, but there was the tremendous loss in transmitting by belts and shafting to the various departments. He concluded that the advantages of electric driving to works of medium size, say anything up to

Digitized by Google

200 h.p., are all in favour of the consumer, and in some smaller works the saving was very large. He did not think the advantages were fully realised in Dundee, or there would be greater demand for electric power from the Corporation supply.

Tramcar Obstruction.—Scarcely a week passes without the time of the magistrates being occupied with cases of tramcar obstruction. Sometimes the defendants raise technical points of a more or less frivolous character; more often the obstruction is clearly deliberate. For some reason, drivers of vehicles in general experience a peculiar relish in hindering the tramcar, and especially do they revel in "sticking up" the electric tramcar. In one case we recorded last week a van driver kept his vehicle in front of a car for three-quarters of a mile, driving slowly all the time. It is not apparent whether these individuals regard such antics as capital jokes or whether they are actuated by "pure cussedness," but in either case they are a distinct public nuisance. After the number of offenders that have been fined one would have expected drivers to take heed, but week after week they cheerfully comply with the pecuniary penalties for indulging in this pastime. It is consequently a little difficult to legislate for people who thus wilfully disorganise tramcar services and cause delay to a number of passengers. In the grosser cases it could scarcely be deemed tyrannical if the delinquents were deprived of the option of the fine which they discharge with such complacency. These little pleasantries become rather expensive luxuries, however, when they cost 78s., plus costs, as occurred in the case referred above; and a few more fines of this order will probably achieve a good deal towards relieving tramway owners and the public from a long-standing annoyance.

Manchester Section Mixture.—The Manchester Section of the Institution of Electrical Engineers opened the session at the Grand Hotel last Friday with Mr. C. D. Taite's chairman's address and a smoking concert. The evening was also remarkable as giving Mr. A. S. Giles, who is just relinquishing the post of chief electrical and tramways engineer at Blackburn, an opportunity of saying farewell to his friends. His coming departure for abroad has been the cause of considerable interest in the district, partly on account of the salary that he will command (£1,800 a year, according to the Press), and partly because his destination had not been publicly made known. This was announced to be Cape Town, and it is understood that Mr. Giles will direct the operations of the local tramway company. Mr. C. D. Taite, after reading his address, which we are publishing, took the opportunity of congratulating Mr. Giles on his success in obtaining his new position, and referred to the loss he would be to the section, to which he had given considerable assistance. Later in the evening Mr. Giles very appropriately rendered "Off to Philadelphy," which took the meeting by storm, and a double chorus. The concert itself was remarkable for the number of "shop" ditties sung, Mr. P. C. Pope and Mr. B. Welbourn being the offenders with "A Dynamo Legend," "The Institution Pilgrimage," and "Ballydoneraile" respectively. Mr. F. P. Wood gave "Der Beiden Grenadiere" in German, which the waiters greeted most enthusiastically. A string and piano trio, while not up to the Gatehouse standard, were much appreciated, and Mr. Mr. J. M. Gibson also sang.

Popular Information on Telegraph Wires.—We have come across a most interesting article in a recent ssue of *Pearson's Weekly*, entitled "Tired Telegraph Wires." The information is so novel that it will take electrical engineers completely by surprise, and they will derive not only profit, but also amusement from its perusal. We have not space to reprint the whole of the column article, but the following three extracts are particularly interesting: "There is a principle of telegraphy known to all telegraph operators called the 'K. R. law,' which says that if the wire is in perfect working order, the full speed of the electric circuit will be obtained directly it is switched on. Supposing, for instance, an operator in London telegraphed the word 'Come,' letter by letter, to an operator in Brighton, the C would arrive rather more slowly than the remaining letters, if transmitted over a tired wire, for once the message has started it goes just as quickly over a tired wire as over one in full working order. The interval between the arrival of C and the next letter would be almost infinitesimal, but to a practised operator the slight delay in the arrival of the first letter would be quite noticeable, and he would report the matter to the engineer's department, where it would be at once ascertained where the earth wire was misplaced, and a couple of men dispatched to settle it. . . . Without what is known as the resistance of the electricity during its passage along the wires, it would be impossible to send messages of any length, for the circuit of electricity would be completed too quickly, and frequent breaks would then occur in a message of any length. . . . Every mile of telegraph wire costs about 5s. a day to maintain in proper condition." There is hardly need for us to comment on these paragraphs, as our readers are quite capable of drawing their own conclusions from them.

A Novel Compass.—It is reported that satisfactory results have attended the use of the electrical apparatus devised by a French inventor, M. Heit, in connection with the compass for registering automatically, minute by minute, the direction followed by the vessel. The compass card, instead of having at its centre an agate resting on a fixed steel point, is fixed on a steel pivot, which rests on a fixed agate. The latter is immersed in a small quantity of mercury, which serves to conduct the current of electricity that makes possible the registering of the movements of the compass. For this purpose the card has attached to it a small silver index, which is kept in constant electrical communication with the pivot by a fine and flexible wire. In the usual position this index does not touch the fixed basin surrounding the card, but by means of the electrical current the circuit is rapidly closed and opened, with the result that the angle of the boat with the meridian is registered. For this purpose the basin is divided into a certain number of sections, isolated from each other and corresponding in each case to a special circuit, the registration being made on a sheet of paper by means of a spark produced by a small induction coil. Certain sections of the basin also correspond to certain call bells, the commander thus being instantly informed of any abnormal deviation in the direction of the vessel. The apparatus also gives the speed of the boat by registering the revolutions of the screws, a circuit being closed and a signal sent to the receiver at each stroke of the engine. In case of accident, reference to the chart enables any alteration in the position of the vessel, and the time of such alteration, to be detected, so that responsibility can be located.

Royal Meteorological Society.—The opening meeting of the session was held on the 16th inst. at the Institution of Civil Engineers, Captain D. Wilson Barker, F.R.S.E., president, in the chair. A paper on "Meteorological Observing in the Antarctic" was read by Lieutenant C. Royds, R.N., of the "Discovery." In the South Polar regions the exploring party encountered fewer fogs than they expected. Mr. Royds's experiences brought out the peculiar difficulties under which observers labour in those high latitudes. The severest cold experienced was about

Digitized by Google

67deg. below zero, or almost 100deg. of frost. In one of the worst blizzards the wind blew at the rate of 85 miles an hour. The party experienced, probably for the first time in man's history, 24 hours of continuous sunshine, this being in the Antarctic summer, when the sun never sets. Mr. F. J. Brodie, F.R.Met.Soc., then read a paper on "The Decrease of Fog in London during Recent Years." He had investigated the number of days of fog reported at Brixton, the London station of the Meteorological Office, for the 33 years 1871-1903, and found that the mean annual number of fog days was 55, of which 45 occurred in the winter half of the year, and only 10 in the summer half. December is the foggiest month with 9·5, the next being November with 8 5, January with 8·2, and October with 7·8. The clearest months are July with 0 4, June with 0·6, and May with 0 8. The greatest number of fog days were 86 in 1886, and 83 in 1887, and the least 13 in 1900 and 26 in 1903. Dividing the 33 years into three periods of 11 years each, the author showed that the mean for 1871-1881 was 55, for 1882-1892 it was 69, while for 1893-1903 it was only 41, there being thus a very marked decrease in the number of days with fog during the last 11 years. Mr. Brodie considered it probable that improved domestic grates and stoves, the enforcement of the law against smoke-emitting factories, the substitution of incandescent gas burners for the older forms, and of electric light for street illumination, and the adoption of many thousands of gas stoves in place of grates burning coal, had all, by bettering the combustion of fuel and the giving off of fewer solid particles, tended to the less frequent creation of fog and to its less deleterious quality.

Electrical Tool Driving.—The last issue of the *Journal* of the Franklin Institute contains an interesting discussion on the individual operation of machine tools by electric motors, which took place before the Franklin Institute this year. It was opened by Mr. Charles Day, and a number of experts joined in the discussion. The whole matter, reproduced in the *Journal*, is most interesting, and the speakers were almost unanimously in favour of having a single motor on each machine tool. Thus, from a quotation by one of the speakers, he concluded that it is to the advantage of any machine shop to put an individual motor on a 16in. lathe, provided this tool is busy throughout the shop year—that is, keeps one man busy all the time on a variety of work. It is advantageous to put an individual motor on all variable speed tools which are busy throughout the shop year, regardless of their horse-power requirements. It is also to be deduced that since no credit has been allowed for shafting, or motors allowed for group driving, it will actually pay to change existing shops to individual motor drives. The introducer of the discussion alluded to the great improvement in motor controllers for securing variable speeds which have been made during recent years. Everything depended on the proper selection of the motors and controllers, followed by intelligent installation and operation. One of the gentlemen taking part in the discussion emphasised the fact that the advantages possessed by the individual motor drive ultimately depended on the reliability of the apparatus. Another speaker, too, emphasised the fact that electrically-operated machine tools have paid well, giving the following reasons for his conclusions—*i.e.*, better placement of tools, especially the larger ones; the operation of powerful portable apparatus for use on the very largest work; better crane service due to the absence of belts; the inestimable boon of the electric crane itself; better light; less dirt; less danger to employés; lighter overhead construction necessary in new factories due to non-existence of countershaft, etc.; fuel economy in many (but not all) instances; and last, and greatest of all, abundance of power to pull a cut of the most generous proportions at the highest speed permissible with the new high-speed tool steels.

Institution of Junior Engineers.—On Friday last Mr. W. H. Lindley, M.I.C.E., delivered an interesting presidential address to the above institution on municipal engineering on the Continent. Mr. Lindley's own work in advising Continental corporations places him in an excellent position to give a *résumé* of this subject, and we are pleased to notice that so much of the work mentioned was done under the control of English engineers. Mr. Lindley divided his subject into four headings, dealing respectively with waterworks, sewage works, electric lighting, and miscellaneous work, such as the design of harbours and plans for the extension of towns, etc. It is with his remarks under the third heading that we are interested, and with the particulars he gives of the electric distribution systems at Berlin, Frankfort, and Elberfeld. He naturally referred to the great fight which raged between 1889 and 1892 as to the best system for lighting the city of Frankfort. The battle of the systems was exceedingly severe, but Mr. Lindley succeeded in inducing the Frankfort Corporation to put their money on a single-phase alternate-current system, which decision has been fully justified since. In his presidential address he referred to the details of the Frankfort system, with its small loss in the high-tension mains which supply the low-tension distribution network through transformers. These are usually placed in underground chambers. He also defended the employment of large generating units and cheap rates for the supply of motors. He then proceeded to describe the Elberfeld works, which were under his direction in 1898. Here the high-pressure voltage has been raised from 3,000 volts to 4,000 volts, and the maximum drop in the high-voltage mains limited to 2½ per cent. The low-tension network was designed for a maximum loss of only 1⅓ per cent., so that large quantities of electrical energy can be supplied at any point of the district without upsetting the voltage regulation. Mr. Lindley also gave particulars of the introduction of the Parsons turbo-generator of 1,250 kw. at Elberfeld. The economy from the use of the turbines was great, and the works cost had been reduced to 0·7d. per unit and the coal consumption to 2·65lb. per unit. In conclusion, Mr. Lindley advocated the interchange of visits of inspection between England and the Continent, so that engineers might be kept well informed of the latest practices.

Society of Arts.—The one hundred and fifty-first session of the society was opened on the 16th inst. by the vice-president, Sir William Abney, who strongly recommended that certain work performed by semi-private institutions should be undertaken by the State. He considered that the Board of Education ought to become responsible for the examinations of the Society of Arts, while the case for the assumption by the Government of some of the administrative functions at present discharged by the Royal Society was even stronger. In regard to such important institutions as the Meteorological Office and the National Physical Laboratory, it seemed to him self-evident that these should henceforth be controlled by a department of State on the advice of a scientific body. While meteorological science had been much retarded in Great Britain by want of funds, our American cousins deemed it of sufficient importance to be recognised by the State, and spent nearly a quarter of a million per annum upon work for which our Meteorological Committee expended £15,300. If weather forecasts were any good at all—and from 68 to 75 per cent. of them were successful—they ought to be made as good as possible. There

Digitized by Google

was no doubt that kite and balloon observations, together with the use of wireless telegraphy in mid-ocean, would give a still higher percentage of successful forecasts, but the additions must remain in abeyance until the money limit which had been enforced for so many years was removed. It will be remembered that a committee reported last June in favour of the reorganisation of the Meteorological Office under the Board of Agriculture, and suggested that wireless telegraphy should be employed for recording weather in the Atlantic; but nothing has since been heard of the recommendations. With regard to the National Physical Laboratory, the term for which the Government grant was made expires in March, and Sir William declared that the Treasury will have to review the situation, as the development of the laboratory has become a public necessity. Great Britain, he concluded, had no reason to be ashamed of the work which had been accomplished, though it had of the grants. In the United States the public need was liberally catered for by a public department, as it should be. If the English Government would recognise the fact that the institutions referred to discharged essential public services, he believed that Parliament would vote the supplies in the same ungrudging spirit as the American Congress had done.

Corps of Electrical Engineers (R.V.)—A goodly assemblage of this corps attended the annual regimental dinner at the Criterion on Saturday last, Colonel Crompton, C.B., the commanding officer, presiding. The guests included Colonel R. C. Maxwell, A.A.G., R.E., Colonel W. Pitt, C.R.E., Colonel Stephenson, Prof. J. A. Ewing, F.R.S. (director of naval education), Major Dumbleton, Major Erskine, and Captain Simon, and the officers of the corps comprised Captain Dumble (of the permanent staff) and Captains O'Shaughnessy, Phillips, Edgcumbe, Biggs, and Leaf. Letters of regret for their unavoidable absence were received from Lord Kelvin, General Sir Henry Mackinnon, Sir William White, Sir Carne Rasch, and Sir John Wolfe Barry. After dinner the company had to submit to the photographer, following which came the toasts, interspersed with some delightful harmony. Following the loyal toasts, Colonel Crompton gave "Our Guests," pointing out that in a corps of this kind it was necessary to confine the invitations to those with technical knowledge. Colonel Maxwell, in responding, dwelt at length upon the services rendered by the Electrical Engineers in the South African war. He considered that this association of the engineering profession with the Royal Engineers would constitute a highly potential force, because, as civil engineers were specialists, their efficiency could be relied upon. He thought that the link might be strengthened by Volunteer officers doing a little training with the regulars. Prof. Ewing recalled the fact that the formation of the corps was suggested eight years ago by his old friend the late Dr. J. Hopkinson. After alluding to the progress that had been made, Prof. Ewing remarked that the warfare of the future would be a contest between the opposing engineers. Colonel W. Pitt, C.R.E., in proposing "The Corps," congratulated the members upon maintaining a high standard of efficiency, which, he predicted, would be further improved by the new system of company organisation The United States army had paid the corps the sincerest form of flattery by instituting a similar force. Colonel Crompton, in returning thanks on behalf of the corps, said that although progress had been made, he was not yet satisfied. Alluding to the increased scope of the corps, he remarked that at first only searchlight and mining operations were contemplated, but they soon found that there was a wider field of usefulness for them. When the corps had received visits from naval men, he had been struck by the intelligence and directness of the questions put by the visitors. On all sides they displayed indications of admirable training, and it was his ambition that the corps should emulate them by becoming the handy men of the Army. The new system of organisation would facilitate progress, and if by the end of the next twelvemonth the corps did not reach the standard he had set them, he should feel greatly disappointed. He mentioned that when in the States recently with the touring party, the Commander-in-Chief of the United States army had spoken to him of the corps in very complimentary terms. After this Colonel Crompton gave "The Permanent Staff," dwelling upon the willingness exhibited by its members. In responding, Captain Dumble (adjutant of the corps) pointed out that the relations between the permanent staff and the members of this corps might be termed unique. Although the permanent staff were in charge of the corps, they could not profess to teach its members much, seeing that the latter were experts in engineering. He joined with Prof. Ewing in appreciating the corps' mission, which was admirably crystallised in their new motto—"Ars martis comes." The organisation of the corps into regular companies would, he was confident, greatly promote efficiency, and also conduce materially towards economy. The toasts concluded with "The Press," proposed by Captain O'Shaughnessy. Admirable entertainment was provided by Messrs. T. E. Gatehouse, Chas. Corner, and S. G. Norris, and Miss Carrie Tubb.

Standard High-Voltage for Transmission.—Dr. F. A. C. Perrine in his paper before the electric power transmission section of the St. Louis Congress, dealt with American practice in high-tension line construction and operation. Speaking of standard voltages he said: "The work of the transmission engineer lies in fields so essentially dissimilar that, even in spite of this general tendency, it may be difficult at first view to ascertain what is the American practice in work of this class. On closer examination one finds, however, this work falling into natural groups dependent on the length of transmission and the voltage employed, though what has been done has been materially modified by the date of erection, since during the past 10 years modifications in the arts have been necessarily reflected in the types of construction. The general groups have been somewhat decided by the manufacturers of machinery, who have presented as preferable certain available voltages. Above 2,400 volts, where transmission proper really begins, the first voltage now commonly employed is 6,600, which figure has been established as standard by the needs of the lighting plants in the great cities, and has been adopted by the transmission companies in place of either a higher or lower voltage, mainly because it is a standard. For this voltage direct generation at high pressure is almost invariably used. The next high voltage now commonly employed, and now practically the first one for which step-up transformers are used, is 15,000. During the past few years this has taken the place of transmissions at 10,000, 12,000, and 13,000; and it is to-day the established voltage for high-tension electric railways, the general reason for its establishment as a standard being that this voltage is not more difficult to handle, as regards insulation or switching, than the three last-mentioned lower voltages, and, furthermore, that where the lower voltages have been previously established, the sphere of operation of the transmission plant has been found to be rather too much limited. There are in the Rocky Mountain region and west a great number of the older plants operating at 10,000 volts, and whenever direct high-voltage generation has been attempted, voltages of from 12,000 to 13,000 volts are used; but, at the same time, the majority of the

Digitized by Google

plants which have used the lower pressures in the past, to-day have circuits with special transformers operating at the higher figure. The next step is to 25,000 volts, which is the highest figure reached without special study of insulators, switches, and lightning arresters. This voltage has been successfully handled without serious trouble during the past six years. A voltage of 35,000 is employed in a number of plants built about five years ago, and at this figure the special difficulties due to line capacity, insulator size, erratic lightning arrester effects, and switching begin to make themselves seriously felt. Above 33,000 volts the standard voltage is called 60,000, although in all plants that have heretofore been established to operate at this pressure there have been installed transformers arranged for connection to various voltages of from 40,000 to 60,000 volts, and the majority of these plants are to-day operating at about 50,000 volts, some of them being unable to operate at the highest pressure on account of the character of line insulators originally installed. In the choice of voltage for any transmission it is considered the best practice to establish it at the rate of 1,000 volts per mile, provided the length of transmission be not above 60 miles, since above 60,000 volts no commercial work has been regularly attempted. In the table recently presented by the Transmission Committee of the American Institute of Electrical Engineers, the highest average voltage per mile for any one class in their report is 840; but in examining this table it must be remembered that their correspondents have reported the total length of line in service, so that if a plant operated two lines 15 miles each in length at 1,500 volts, their table would indicate an operation of 500 volts per mile, although for each line the transmission was at 1,000 volts per mile."

Four-Motor Equipment with a Two-Motor Controller.—Mr. E. Taylor contributes an article on this subject to the *Street Railway Journal*. He points out that when using a two-motor controller on a four-motor equipment the motors must necessarily be arranged in two sets of two motors, each set having the armatures and fields connected in multiple, with a jumper between the positive field leads. With this arrangement a slight difference in the relative resistance of the fields in either pair will throw the fields out of balance, distorting the magnetic circuit of the weaker. Another effect is an excessive flow of current through the armature of one motor, unduly heating it and destroying the insulation. The author considers that such defects are inherent with two-motor controllers. A concrete example of the author's argument follows. The four diagrams represent respectively four-motor equipment, with two-motor controller, in series; the same in multiple; four-motor equipment, with four-motor controller, in series; and the same in multiple. The following illustration is based on the assumption that the connections shown in the diagrams are strictly followed. A General Electric type 800 motor field is ·4 ohm. If the field of motor No. 1 has a lower resistance than that of No. 3, the initial current passed through them will divide, the greater current flowing through No. 1, the lower resistance field. For instance, if a current of 200 amperes was flowing through one set of motors, say Nos. 1 and 3 (Fig. 2), and the field of No. 1 had only half the resistance of that of motor No. 3, 133 amperes would flow through field No. 1 and only 67 amperes through that of No. 3. This would excite a strong magnetic field in motor No. 1, which will build up a high counter E.M.F. in No. 1 armature. It follows that with a high counter E.M.F. the number of amperes flowing through No. 1 armature would be proportionately low; on the other hand, the magnetic field of motor No. 3 will be comparatively weak, and hence there will be a lower counter E.M.F. and a correspondingly higher number of amperes flowing through the No. 3 armature. This condition will, of course, be aggravated as speed is increased. The result is that armature No. 1 has approximately 50 amperes, while No. 3 has 150 amperes, and field No. 1 has 133 amperes, while that of mtoor No. 3 has only 67 amperes. Taking the conditions under which each motor is running separately, motor No. 1 has 50 amperes

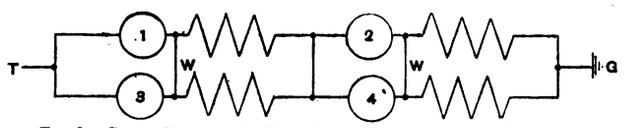

FIG. 1.—Connections for the Four-Motor Equipment, with Two-Motor Controller—in Series.

passing through its armature and 133 through its field—an abnormal condition, but not likely to produce any ill-effects. Motor No. 2 has 150 amperes passing through its armature and only 67 through its field, a condition which is radically wrong and directly in opposition to all theories of motor design or operation. The trouble occurs here, and the author explains the action of the machinery at some length. Railway motors are designed

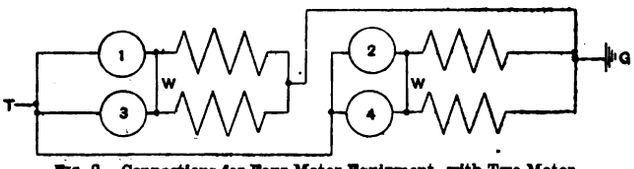

FIG. 2.—Connections for Four-Motor Equipment, with Two-Motor Controller—in Multiple.

with the intention of keeping the neutral point at a fixed location, as it is impossible to trim the brushes for the load. This works out very well when the armature and field currents are identical, as when strong currents occur in the armature there is a proportionately stronger field to overcome the increased reactance of the armature, thereby holding the neutral point fairly constant; but with 150 amperes in the armature and 67 in the field

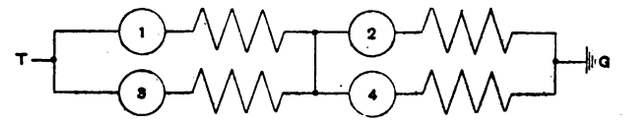

FIG. 3.—Regular Connections for Four-Motor Equipments, with the Four-Motor Controller—in Series.

there is a very strong current in the armature, reacting and setting up cross-magnetisation, which tends to shift and distort the field, with consequent change of the neutral point. The brushes being in a fixed position, and, therefore, not following the neutral points, cause pronounced sparking, as they are unable to properly commutate the heavy currents which are passed through them. The sparking tends to carbonise the brush-holder and armature,

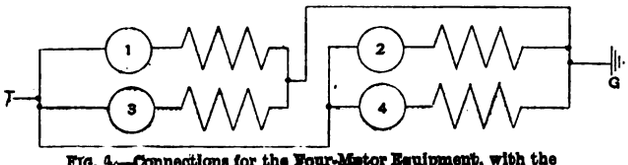

FIG. 4.—Connections for the Four-Motor Equipment, with the Four-Motor Controller—in Multiple.

and greatly overheats the commutator, so that the leads become unsoldered. Another effect is that the excessive current passing through this armature greatly heats the windings, which destroys the insulation and causes short-circuits and grounds. From Figs. 3 and 4 it will be seen that such conditions are impossible with a four-motor controller, as the current in the armature and the field is the same, thus holding the neutral point practically constant.

THE FARADAY SOCIETY.

At the meeting of the Faraday Society on Wednesday two papers were down for discussion, of which the following notes give a general idea.

The Potential of the Hydrogen-Oxygen Cell.

BY FRANCIS JOSEPH BRISLEE, M.SC.

The potential of the galvanic cell—

Platinised platinum Charged with hydrogen | $\frac{N}{1}$ acid | Platinised platinum Charged with oxygen

has been measured by various experimenters and found to lie between 1·076 and 1·14 volts.

In these investigations two lines of work were followed: (1) the electrodes were polarised by electrolysis, the electrolysis extending over two or three days; and (2) the electrodes were freed from gases as completely as possible, and then the respective gases passed through the liquid and the potential measured from time to time until constant. By these means two potential limits were obtained, the first starting from a high potential and gradually sinking, and the second rising to a constant value. When the potentials were constant to about one to two millivolts, the effect of the addition of the various substances was tried.

A series of measurements of the hydrogen-oxygen potential employing the gases obtained by methods fully detailed in the paper gave the following result:

Source of the oxygen and hydrogen.	Potential of $^{Pt}H_2/\frac{N}{1}H_2SO_4/^{Pt}O_2$. T = 18deg. C.
Electrolytic	1·0820 volts.
Aluminium and NaOH, and permanganate	1·0830 ,,
Zinc and hydrochloric acid, Brin's oxygen	1·0818 ,,

Complete details of the apparatus used and the experiments carried out are given in the paper, while the author draws the following conclusions. In the foregoing research the influence of the addition of varying quantities of hydrogen peroxide, persulphate, and ozone upon the oxygen potential have been investigated. The results can be briefly stated as follows: (1) the addition of hydrogen peroxide reduces the oxygen potential; (2) persulphates or ozone increase the oxygen potential and diminish the rate of discharge of oxygen by an electrode supersaturated with oxygen by electrolysis; (3) by employing electrodes of extremely thin platinum deposited upon glass and platinised, the same potential was obtained independently of the method of charging the electrodes with oxygen; (4) the results obtained with the thin platinised platinum electrodes show a good agreement with the potential calculated from the Helmholtz formula.

Recent Investigations Bearing on the Theory of Electrolytic Dissociation.

BY LOUIS KAHLENBERG, PH.D., PROFESSOR OF PHYSICAL CHEMISTRY IN THE UNIVERSITY OF WISCONSIN.

In creating the theory of electrolytic dissociation, the phenomena of actual electrolysis have played a minor part. The changes of concentration of the electrolyte around the electrodes, the elevation of the temperature observed during the passage of the current, and the fact that when polarisation is prevented, electrolytes obey Ohm's law, were all explained many years before the existence of the theory of electrolytic dissociation. Indeed, the hypothesis of Clausius, which displaced the old Grotthus theory and brought conceptions of electrolysis into harmony with thermodynamic requirements, is by many chemists—and physicists still regarded as the best mechanical explanation of the electrolytic process, when all facts are fully considered.

Briefly stated, the theory of electrolytic dissociation is based upon the observation that for a goodly number of aqueous conducting solutions the so-called molecular conductivity increases with the dilution; that osmotic pressure, lowering of the freezing point, elevation of the boiling point, or lowering of the vapour tension of such solutions is abnormally great—*i.e.*, that it is greater than for non-conducting solutions, the behaviour of which, it is asserted, conforms to the requirements of the gas equation; and that the so-called degree of electrolytic dissociation may be calculated from the electrical conductivity of the solution, or from its osmotic pressure, its boiling point, freezing point, or vapour tension. Indeed, the dissociation hypothesis is vitally connected with van't Hoff's theory of solution. The latter claims that dilute solutions behave according to the equation $PV = iRT$, in which the factor i is unity for non-electrolytes. The analogy between a gas and a solution has been recognised so long that it would be difficult to state when the idea originated; but van't Hoff, by using Pfeffer's direct measurements of osmotic pressure, sought to show that dilute solutions obey the gas laws. In this he was successful, in that he had to introduce the factor i above mentioned, which varies for different solutes in the same solvent, and even for different concentrations of the same solute in a given solvent. An examination of the original tables published by Arrhenius shows that the factor i is by no means always unity for aqueous non-electrolytic solutions, nor does it always vary more from unity in the case of solutions of very considerable conductivity than in the case of non-electrolytes, but for a goodly number of excellent electrolytes i is materially greater than unity. The latter fact was utilised by Arrhenius in his endeavour to show that the factor i exceeds unity for electrolytic conductors, and increases with the dilution, as does the so-called molecular conductivity. And thus upon the assumption that free ions, part-molecules charged with electricity, exist in an electrolyte, and act like so many molecules, the general statement which van't Hoff had made for solutions was upheld—namely, that dilute solutions having the same temperature and the same osmotic pressure contain the same number of dissolved molecules.

The author contended that the facts presented by Arrhenius in his original article are not sufficient to serve as a basis for the assumption of electrolytic dissociation in solutions; and that while isolated facts may here and there be interpreted by means of the dissociation theory, the bulk of experimental evidence gathered since 1887 speaks strongly against the theory.

It is a well-known fact that the dissociation theory cannot be harmonised with the law of mass action, and that this constitutes a strong argument against the hypothesis. For solutions of weak organic acids in water, to be sure, Ostwald succeeded in computing a series of constants by means of the formula expressing his well-known dilution law, growing out of an attempt to apply the law of mass action to electrolytic dissociation. But an examination of the constants obtained for these weak acids reveals the fact that the agreement is, after all, only rough; furthermore, the attempt to apply the dilution formula to electrolytes par excellence has utterly failed, and yet the advocates of the dissociation theory continue to calculate the so-called solubility product which frequently involves the application of the law of mass action to strong electrolytes. Attempts made by Lincoln to apply the dilution formula to electrolytes in non-aqueous solutions of about the same order of conductivity as that of some of the solutions of weak organic acids in water have also proved futile. How can the formula possibly hold in cases where the molecular conductivity remains practically constant, or decreases as the dilution increases? Rudolphi and also van't Hoff have sought to amend the formula by changing the exponents so that constants would result from the observed data in special cases. While thus better "constants" were obtained in these instances, the altered formulæ proved entirely unsatisfactory in other cases; and then, too, it must be added that the alterations made the formulæ simply empirical in character, without any theoretical basis.

The difficulties met in applying the Nernst formula for calculating the E M F's of galvanic cells have been discussed in special papers, to which the reader is referred. It may be remarked here, however, that in the work on E M F's especially, many of the solutions used by advocates of the dissociation theory were far from dilute; and at best the agreement between calculated and observed values leaves much to be desired. Many colloidal solutions coagulate when treated with solutions that conduct electrolytically. Attempts have been made to ascribe this coagulative power

Digitized by Google

to the free ions which the electrolyte is supposed to contain. It is true, however, that the power to coagulate colloidal solutions is by no means confined to electrolytic solutions; and hence anyone claiming, for example, that sodium chloride solution coagulates colloids because it is an electrolyte must assume the burden of proving his proposition.

The theory of electrolytic dissociation is unable to furnish a satisfactory explanation of the phenomena in aqueous solutions, but it is in the realm of non-aqueous solutions that the hypothesis proves especially impotent. When the theory was promulgated, but few non-aqueous solutions had been examined as to their power to conduct the current, and those few solutions in which ether, alcohol chloroform, and hydrocarbons, for instance, were the solvents employed, were found to be poor conductors. So the idea that only aqueous solutions conduct electricity to any considerable extent gained ground and held sway for a number of years with remarkable tenacity, the view being strengthened by the fact that in the solvents just mentioned molecular weights as determined by boiling-point, or, where possible, by freezing-point methods, were not "abnormally" low, as in the case of solutions of many ordinary salts in water. But now we know of non-aqueous solutions which are as good and even better conductors of electricity than aqueous solutions; and these solutions, when tested by the methods of determining molecular weights just mentioned, yield results that are generally higher than those computed from the formulæ of the solutes; only exceptionally is the reverse the case. In the course of my work on non-aqueous solutions I have pointed out numerous examples of this, and recently the splendid researches of Walden have established many more. His work on solutions in liquid sulphur dioxide especially shows that in this solvent "abormally" *high* molecular weights are generally found in the case of solutions of excellent conducting power. The field of non-aqueous solutions is a very large one, and it is here that the theory of electrolytic dissociation can really be tested. It is here that the fact that the theory is untenable becomes particularly apparent. Whetham's statement that work with non-aqueous solutions is rendered difficult by the fact that with some solvents like alcohol freezing-point work is impossible, is hardly valid, for such solutions may be readily examined by vapour tension or boiling-point methods. It is true that in operating with many non-aqueous solutions, like liquid ammonia, liquid sulphur dioxide, liquid hydrocyanic acid, special difficulties and dangers present themselves; but these are generally quite surmountable, and, indeed, often it is fully as easy to investigate a non-aqueous solution as one in which water is the solvent. It simply has not yet become generally fashionable to investigate non-aqueous electrolytic solutions. When this work is taken in hand by more investigators, the fact that the dissociation theory is useless and misleading will gain ground more rapidly.

INSTITUTION OF CIVIL ENGINEERS.

At the ordinary meeting on Nov. 22, Sir Guilford L. Molesworth, K.C.I.E., president, in the chair, the paper read was "Distribution of Electrical Energy," by John F. C. Snell, M.I.C.E. The following is an abstract of this communication:

The paper deals first with the attitude of the Legislature towards the electrical industry, and recites some of the points of the 1882 Electric Lighting Act, which retarded the progress of electrical development. It then deals with the improved clauses under the 1888 Electric Lighting Act. Reference is made to the removal of restrictions upon undertakers which would be effected by the Electricity Supply Bill, promoted by the Board of Trade in the last session of Parliament, and a hope is expressed that this will soon become law. Mention is also made of the falling in of the leases of borough tramways, and the effect of electrical traction upon the output and load factor of the generating stations. The author then describes the various systems by which electricity is at present distributed, including direct-current two and three wire distribution; direct-current high-tension generation and low-tension distribution; single-phase, two and three phase currents, high-tension generation and low-tension distribution; three-phase high-tension and low-tension direct-current distribution.

After dealing with the limits of pressure as defined by the Board of Trade, and the results of the work of the Engineering Standards Committee in settling upon standard periodicities, the systems of supply are more thoroughly criticised, and the single-phase system is set aside as being inapplicable for general supply, as is also the direct-current high-tension system. The author is of opinion that the distributing systems which are likely to be adopted in the future are: (1) direct-current, two or three wire, for small districts; (2) single-phase high-tension for railways; (3) two-phase high-tension generation and low-tension distribution (for existing single-phase systems of general supply); (4) three-phase high-tension generation and direct-current low-tension distribution (for existing direct-current systems in large districts, and for railways of short length); (5) three-phase high-tension generation and low-tension three-phase or six-phase distribution (for entirely new and large districts).

Diagrams accompanying the paper demonstrate the economical radii of supply by direct current at 500 volts for different loads transmitted and by the high-tension sub-station method, the result being that above the undermentioned distances the high-tension method is more economical—viz.:

Kilowatts.	Economical radius.
250	1·6 miles.
500	1·25 ,,
1,000	1·06 ,,

With regard to the effect of storage at sub-stations, the author believes that storage will be more largely resorted to in the future; and figures are given in support of this view. He then proceeds to discuss the economical limit of pressure for high-tension supply by underground cables, and gives curves to show that for general purposes in Great Britain 6,600 volts is approximately the economical pressure. The effect of the cost of insulation of extra high-tension cables is also discussed. The paper next deals with the cost of overhead transmission of high-tension currents, and reasons for fixing upon a pressure of 20,000 volts in this country are given. As to the cost of supply, the ideal figure given by Colonel Crompton in 1894 is stated to have been surpassed. A new ideal figure is given by the author, based upon further experience gained in the past 10 years, and he predicts the costs which are likely to be charged to various classes of consumer. Turning to transmission lines, a description is given of the practice adopted in extra high-tension underground cables, and the risks which have to be guarded against. The mechanical and electrical construction of overhead lines for extra high pressures is also dealt with.

The paper then enumerates various classes of sub-station, covering static transformers for three phase low-tension distribution; static transformers with rotary converters for direct-current distribution; and synchronous or induction motor-generators for direct-current distribution at the higher periodicity. Descriptions follow of the various sub-stations erected by the author, with curves of their outputs and particulars of their efficiencies. The various methods of distributing energy at low pressure are classed as follows: I.—Conduit or draw-in system: (1) bare copper-strip systems, strained and unstrained; (2) cables insulated by indiarubber, vulcanised bitumen, or other dielectrics drawn into stoneware casings, Callender-Webber bitumen casings, fibrous conduits, cement casings, and cast-iron or wrought-iron pipes. II.—Buried or solid system: (1) vulcanised bitumen, dialite or other insulated single cables, laid in iron, stoneware, or wooden troughing, and surrounded by molten bitumen or pitch; (2) concentric cables, paper insulated, and lead covered, laid in the same manner; (3) single-phase or concentric cables, each protected by its own sheathing of steel tapes or wires, laid direct in the ground. The relative merits of these systems are fully discussed, and a curve is given showing the respective capital costs of the systems.

The author then deals with the systems of distribution

Digitized by Google

adopted in tramway construction, and their relative advantages and disadvantages. The question of fusing the general network and the fixing of section boxes is gone into fully; the author deciding against fuses, except in concentric networks, and strongly advocating the use of section boxes for sub-dividing the network.

The paper concludes with some particulars of the supply of electrical energy to short and long distance railways. The author believes that a modification of the present third-rail system will remain with short-distance railways, and that improved methods in the application and control of single-phase currents will be adopted for long-distance railways.

BALLYDONERAILE.

(Sung at the Manchester Section Smoker, Nov. 18, 1904.)

Ho! all you 'licthric ingineers, come listen to my tale
Of how they make th' licthric light in Ballydoneraile,
The Works is next the Morturee, the boilers they are fed
Wid annything-come-handy, and sometimes they miss the dead.

The plant was made by local men to benefit the place—
To buy from Saxon foreigners they felt was a dishgrace,
So the engines was by Mulligan, N.B.G.-type machines:
He also built the dynamos, likewise the works latrines.

The cables was by Rafferty, who had ambitious hopes;
He made them from a recipe that acted well wid ropes.
A constant insulation is the mainsman's joy, for such
Is point 00001 ohm, which never varies much.

The switchboard insulation being deal is not so high,
So they put a stove beneath it for to keep the beggar dry.
To help resuscitation from one-hundred-voltage shocks
A keg of Dunville's compound is in every jointer's box.

The engineer is honest and he deals contractors fair;
They do not need to get their dues by presents or by prayer,
For a beautiful example in persuasion has been read
To all the late chief engineers—wid dynamite and lead.

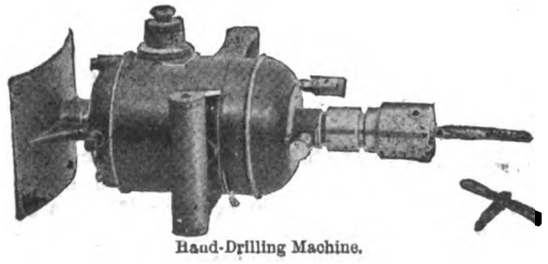
By dint of such good management, the station pays its way;
But when the Income's less than Costs the stoker gets half pay,
The meter reader sacked—and this is never known to fail—
And thus they run the 'licthric Works at Ballydoneraile.

B. C. H. J.

TRADE NOTICES AND NOVELTIES.

Portable Drilling Machine.

The accompanying illustration shows a useful type of hand drilling machine supplied by the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C. This machine is



Hand-Drilling Machine.

fitted with double-reduction gear, and combines strength of construction with lightness, the latter advantage being obtained by the use of aluminium for the non-magnetic parts of the driving motor. The double-reduction gear enables the speed of the drill to be varied, but the machine can be supplied with single-reduction gear if desired—also for working either on continuous-current, alternating-current, or three-phase circuits. Current is switched on the motor by means of a press button attached to the machine itself, whereby economy is effected in the total consumption of energy.

The "Harman" Electric Hoist.

Messrs. R. Harman and Co., 10, Westmoreland-buildings, Aldersgate-street, E.C., have, we understand, placed on the market an "electric hoist" designed to meet the requirements for a small lifting gear, more especially in connection with the building trade. Small dimensions and light weight are among the advantages claimed, a hoist to lift 8cwt. 80ft. per minute weighing only 7cwt. It is fitted with a liquid controller and a magnetic brake. The gearing is of the worm type, provided with a mild-steel worm and gunmetal wormwheel, and ball-thrust bearings, the whole enclosed in a dustproof case, and running in an oil bath.

Some G.E.C. Novelties.

Several novelties are described in the "Progress Sheet" issued by the General Electric Company, Limited, for last month. The first of these is the "Robertson Witelite" lamp, shown in Fig. 1

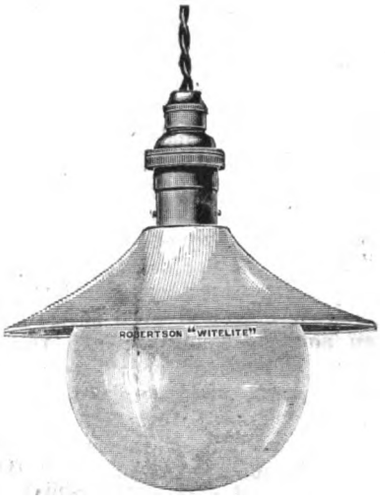


Fig. 1.—The "Robertson Witelite" Lamp.

herewith. This lamp marks a departure from the usual design of incandescent lamps, and is recommended for use in place of ordinary high candle-power lamps. It has a large spherical bulb (without the usual pip), which is frosted or obscured excepting the uppermost part. A small opal shade is provided, so shaped as to give the maximum of light without any sharp shadows. It is further claimed that this combination yields a very agreeable light of a soft white nature, and that although the increase of candle-power is very marked the consumption of current is no greater than that of an ordinary 16-c.p. lamp, while no special holder is required. From the description given it does not appear that any novelty is claimed in regard to the design or composition of the filament of this lamp, and we therefore assume that the large increase of candle-power obtained refers to the percentage of the total light emitted which is usefully employed.

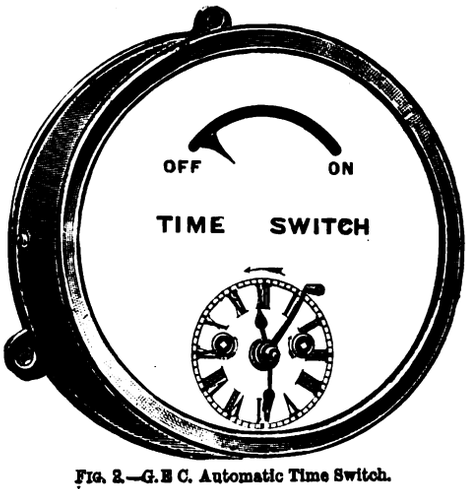

Fig. 2.—G.E.C. Automatic Time Switch.

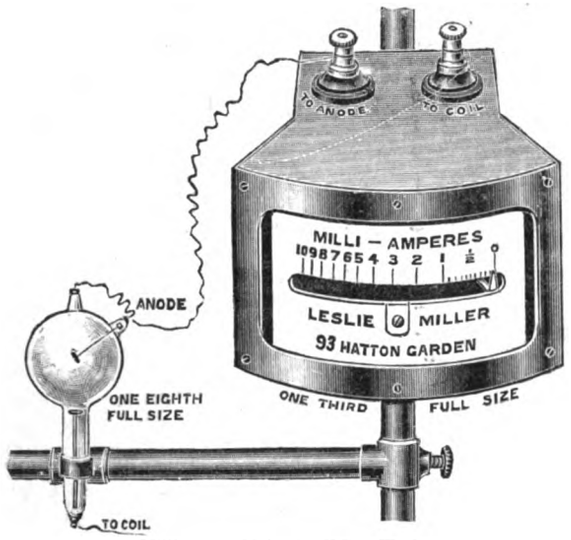
Fig. 2 represents an automatic time switch consisting of a good quality one-day clock combined with a single-pole switch. The clock has a third hand which can be set to any time at which it is desired to open the switch, the clock face being provided with quarter-hour divisions. The mechanism for actuating the switch is somewhat similar to the ordinary alarm movement on a clock. It has a separate spring of its own, which is wound up automatically during the operation of switching the lights on. This is done by half a turn of the clock key in the right-hand hole. When the hands of the clock reach the time set for switching off, a cam releases the alarm movement, and this, running down, operates a series of links releasing the switch, at the same time moving an index pointer on the face of the clock from the word "on" to the word "off." The switch release is also fitted with

Digitized by Google

a weighted escapement, which causes a distinct sound when vibrating to and fro. The arrangement of links for operating the switch is very ingenious, it being impossible to push the switch into the "on" position by means of the index, so that if the key be taken away no unauthorised person can close the switch. The switch is intended for currents of from five to ten amperes at voltages up to 220. Among the other articles dealt with in the publication under notice are some useful forms of outside shop window reflectors.

A Milliampere Meter for Radiographers.

We illustrate herewith a meter which has been introduced by Mr. Leslie Miller, 93, Hatton-garden, London, E C., to enable radiographers to know the quantity and penetrating power of the rays given off by an X-ray tube at any moment. By means of this instrument the intermittent current passing through the tube itself can be measured, like the interrupted current, through the primary winding of the induction coil. In reality, the needle of the instrument indicates in milliamperes a mean of the rapidly dying away impulses it receives. This enables the operator to see clearly when he has reproduced certain favourable conditions, instead of judging the condition of a tube by



Milliampere Meter for X-Ray Work.

the green fluorescence or the effect on a screen. The instrument consists of a delicately-pivoted soft-iron needle with a long aluminium pointer attached to it, which works inside a coil of fine wire. The controlling force is a permanent magnet fixed under the coil. In case the coil is working under bad conditions, so that a reverse current due to the "make" of the circuit passes through the tube, the amount is added to the proper current. When the coil is worked from voltages up to, say, 30 volts, there is no appreciable current at the make. The instrument reads correctly when used as an ordinary milliampere meter for continuous current, and may also be employed to see if an accumulator gives its proper voltage.

PARLIAMENTARY POWERS.

The following applications for electric lighting provisional orders, tramway Bills, and other parliamentary powers are now being advertised in the *London Gazette* and elsewhere.

TRAMWAY AND LIGHT RAILWAY POWERS.

Aberdare District Council; London Southern Tramways Company; West Cumberland Electric Tramways Company (extension of time); Newark Tramways Company; Mansfield Light Railways Company (extensions); Ackworth and Immingham Light Railway Company; Armley and Bramley Tramways (Leeds Corporation); Bradford Corporation (extensions to Wike, etc.); Gorton Urban District Council; London United Tramways Company (extension of time); Whitechapel and Bow Railway (electrical powers); Bury Corporation (extensions and reconstructions); Halifax Corporation (extension powers); Blackpool, St. Annes, and Lytham Tramway Company (for compulsory running powers over Blackpool Corporation lines); Nottingham Corporation (extension of powers); Wellingborough and District Tramroads and Electricity Supply Company; Birmingham Corporation (extension of powers to King's Norton and Yardley, etc.); Croydon Corporation (extension of powers); London County Council (tramway extensions); Liverpool Corporation (extensions); Great Northern, Piccadilly, and Brompton Railway (extensions to Waterloo and confirmation of agreements); Charing Cross, Euston, and Hampstead Railway (extension of powers); Edgware and Hampstead Railway (extension of time and confirmation of agreements); Baker-street and Waterloo Railway (extension of time and confirmation of agreements; Luton Corporation; South Lancashire Tramway Company (extension of time and rearrangement of capital); Wigan Corporation (extensions to Upholland or Orrell and Aspull, etc.); Newark and District Light Railways Company; Accrington Corporation (reconstruction and electrification of existing tramways and construction of new tramways); King's Norton and Northfield Urban District Council.

TRAMWAY POWERS.

Basingstoke and Alton Light Railway Company (speed amendment); Southend and Colchester Light Railway Company; Rhondda Urban District Council (extension of time for tramway purchase); Stratford-upon-Avon (powers to transfer order and other amendments).

ELECTRIC LIGHTING ORDERS AND OTHER SUPPLY POWERS.

Bury Rural District Council; Urban District Council of Golborne; Houghton-le-Spring (transfer of powers); Croydon Corporation (supply in bulk to outside authorities); Hipperholme Urban District Council; Whitby Urban District Council (supply of electric fittings); Southall-Norwood (electric lighting), by the Metropolitan Electric Supply Company; Brentford (electric lighting), by the Metropolitan Electric Supply Company; Haydock Urban District Council; Tewkesbury Corporation; Barton-upon-Irwell, by the Lancashire Electric Power Company; Colne Corporation; Metropolitan Electric Supply Company (powers to supply in bulk, etc.); Hythe Corporation (powers to lay mains outside borough); Little Hulton Urban District Council; Woking Electric Supply Company (extensions to Byfleet, Pyrford, Chobham, and Bisley: Rushden, Higham Ferrers, Irthlingborough, and Thrapston (electric lighting), by E. P. Harvey; Acton (bulk supply), by the Metropolitan Electric Supply Company; Tottington (electric lighting), by the Lancashire Electric Power Company; Carmarthenshire Electric Power Company (transfer of rights to South Wales Electrical Power Distribution Company); Ealing Corporation (supply to adjoining districts, etc.); Charing Cross and Strand Electricity Supply Corporation (for powers to give bulk supply to certain surrounding districts); Bolton Corporation (further powers); Farnham and District Electric Supply Company; Shepton Mallet, by the local gas company; Bristol Corporation (further powers); Eastbourne Corporation (Willingdon extension); Weybridge and Walton-on-Thames Electric Supply (Urban District Supply Company); Clewer and Old Windsor (electric lighting), by the Windsor Electrical Installation Company; Andover (electric lighting) by the reconstructed Andover Gas Company.

FORTHCOMING EVENTS.

FRIDAY, NOV. 25.

North-East Coast Institution of Engineers and Shipbuilders.—At 7.30 p.m., "A Comparison of Vertical and Horizontal Tubes in Water-Tube Boilers," by Mr. W. R. Cummins.

Physical Society.—At 5 p.m., "The Measurement of Small Differences of Phase," by Dr. W. E. Sampner; "The Curvature Method of Teaching Geometrical Optics," by Dr. C. V. Drysdale; "A Rapid Method of Approximate Harmonic Analysis," by Prof. S. P. Thompson; exhibition of specimens of crystals showing the phenomenon of luminous rings, by Prof. S. P. Thompson; and exhibition of apparatus by Prof. Dalby, Mr. Darling, Dr. Drysdale, and Prof. Thompson.

Civil and Mechanical Engineers' Society.—At 3 p.m., visit to Victoria Station in connection with the enlargement works.

SATURDAY, NOV. 26.

Glasgow Technical College.—At 7.30 p.m., "The Electrical Drive of Large Reversing Engines Working Intermittently," by Mr. M. Georgi.

Institution of Electrical Engineers (Students' Section).—Visit to Great Northern, Piccadilly and Brompton Railway (tunnelling).

MONDAY, NOV. 28.

Hull Corporation Telephones.—At 2 30 p.m., opening of exchange.

TUESDAY, NOV. 29.

Institution of Civil Engineers.—At 8 p.m., further discussion on Mr. J. F O Snell's paper, "Distribution of Electrical Energy."

Institution of Electrical Engineers (Manchester Section).—At 7.30 p.m., "Compensated Alternating Current Generators," by Mr. M. Walker.

WEDNESDAY, NOV. 30.

Institution of Electrical Engineers (Students' Section).—At 7 30 p.m., "Motor-Controlling Switchgear," by Mr. L. J. Pumphry.

Society of Arts.—At 8 p.m., "The British Canals Problem," by Mr. A. Lee, J.P.

THURSDAY, DEC. 1.

Institution of Electrical Engineers.—At 7.30 p.m., annual dinner at the Hotel Cecil.

Tramways and Light Railways Association.—At 8 p.m., "Running Powers," by Mr. Stephen Sellon.

Rugby Engineering Society.—At 8 p.m., "Some Notes on High-Speed Electric Railway Work," by Mr. F. W. Carter.

FRIDAY, DEC. 2.

Junior Institution of Engineers.—At 8 p.m., "Some Points of Interest in the Construction of Torpedo-Boats," by Mr. H. E. Yarrow.

Institution of Civil Engineers (Students' Section).—At 8 p.m., "Midland Railway, West Riding Lines: The Construction of Contract No. 1," by Mr. R. F. McCallum.

SATURDAY, DEC. 3.

Institution of Junior Engineers.—Visit to the London Coliseum to inspect its features of engineering interest.

Institution of Electrical Engineers (Manchester Students' Section).—Visit to the Corporation sub-stations.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

EXAMINATIONS.

In our last issue we referred to a scheme which had for its object the consolidation of examinations. The scheme proposed is of limited extent, but the suggestion is so enormously important that we should like to see it adopted almost universally. Broadly speaking, examinations are of two kinds—one for selective purposes, the other as a kind of guarantee that the individual who passes has received a more or less liberal education. So far as examinations generally are concerned, they travel over much the same ground; hence one common examination upon the subjects which form the foundation of all education ought to satisfy every requirement. Specialisation may require individual examination, as does selection, but in no case is examination conclusive. At the best it is a fairly good method of getting rid of responsibility. No one imagines that the man who comes out at the top in the examination will most certainly come out on top in the struggle of life. He possesses the tools, but may not be able to use them to the best advantage, while another with poorer tools may have capacity for better usage. The characteristics required for success in life are not always the same as those required for success in examinations But to hark back. All education is up to a certain point similar in character; it is only when specialisation comes in that differences commence. Take as one example various societies and various professions that admit by examination. Most of these indicate that having passed this, that, or the other examination will be held to satisfy the requirements on general and elementary subjects. These various accepted examinations have grown up in the attempt of far-seeing, energetic men trying to further the desire of education by the multitude. Incentives are given and prizes offered to pass examinations. Education has not always been sought for its own sake, but often for the sake of the prizes offered. We do not object to that; we honour and applaud those who endeavour to increase the knowledge of the people. It, however, seems pretty clear that at the beginning of the twentieth century a time has come when these numberless elementary examinations serve no very good purpose, and that variety might give place to uniformity. A real examination requires an examiner as much as an examinee. It is an intolerable nuisance to come across a lot of amateur examiners, whose sole idea of their work is to propose catch questions—in fact, not to find out what the student knows, but, on the contrary, to stump him. In our mind, one of the worst and most disgraceful forms of newspaper writing is that which deals with the funniosities of examination papers. The funny answers more frequently point to the crass stupidity of the examiner than to the lack of knowledge of the person examined. We wonder that someone with leisure has not long since analysed the value of the questions set, in reply to some of the lucubrations which every now and again appear in print relating to the answers. Not only could the examinations for general elementary knowledge be with advantage consolidated, but also many of the technical examinations. Of course, the one great difficulty in reform is that so many societies derive a large part of their income from examination fees, and while this is the case any movement towards improvement will be troublesome. We really see no valid reason why examinations should not throughout the length and breadth of the land be divided into three: first, for elementary subjects; secondly, for advanced subjects; thirdly, for specialised subjects. Every boy and girl should be put through the mill for the first, all preparing for business and

Digitized by Google

professional careers prepared for the second, while the specialists are easily provided for. It is a big subject, and worthy of the most careful consideration.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

COST OF PRODUCTION AND MR. SIEMENS'S PRESIDENTIAL ADDRESS.

SIR,—Mr. Byng's letter of the 16th inst. is interesting. If it were less academic and more precise, it might even be valuable. Confining one's attention solely to the electrical industries, can Mr. Byng give the volume of the respective internal electrical markets of Great Britain, Germany, and the United States? How many millions' worth of electrical machinery imported from abroad has found its way into our central stations, and how does this amount compare with the value which our own manufacturers have supplied? By what margin have these orders been lost? If Mr. Byng will leave generalities and obtain the compilation of such figures as those I have indicated, he will render a great service to the general community, but possibly a dis-service to the cause he has so strongly at heart.—Yours, etc.,

TURRIS.

THE RICHMOND (SURREY) GUARDIANS AND GERMAN TELEPHONES.

SIR,—To some of your readers the pseudonym "Englishman" appended to the letter published in your last issue must convey the idea of a necessarily disinterested opinion emanating from an unexpected quarter in favour of German telephones in preference to those of English manufacture. To those of us, however, to whom this individual voice sounds familiar, and who are accustomed to hear this plea made by the English agents of the German manufacturers, as if it were some palliation which should have weight with us, the signature does not convey the same idea. Although seeking your courtesy and influence on a matter of public interest, we are aware that your correspondence columns have advantages which, although of much value in themselves, are not possessed by those devoted to advertisement, a very important one being that they are inexpensive. Evidently your correspondent is not slow to appreciate this fact.

My excuse for asking your valued space for this letter must be that "Englishman" apparently thinks by his repeated references to "Disappointed Contractor," with capitals and inverted commas included in the gratuitous *nom de plume*, that he is answering the comments of an imaginary correspondent who has adopted it for himself.

Whilst preferring to choose my own, I am undoubtedly the only individual to whom he can be alluding, and, therefore, hasten to accept the implied challenge and to put him right upon certain facts which are evidently beyond his knowledge.

On more than one occasion, both before and after the acceptance of the tender in question, I visited the architect, and asked him why he had specified German telephones instead of English, as the ratepayers would undoubtedly have expected him to do. He distinctly told me his reason was that he wished to have them all *en suite* (I am quoting his words), and as those that are now at the workhouse are of German manufacture, hence the necessity. From the outset I contested the technical necessity. As a result, I was told that I might quote for the English goods in addition to those specified, and he promised that I should not be put "out of court" thereby, providing that I kept my tenders separate.

It was not until after the matter was settled by the Guardians that I had an opportunity of pointing out to the architect personally that his *en suite* ideas were impossible, seeing that some of the telephones were British, although an inferior grade of the same manufacture as those which I specified. All this, however, was made quite clear in my specification. His reply was that he had nothing to do with the acceptance or rejection of the tenders, that he was not present at the meeting of the Guardians at which this was done, and that he had never even seen my specification and tenders. In answer to this, I contended that the Guardians, whom we could not expect to have technical knowledge, had evidently relied upon him, and that by his specification he had practically excluded the British manufacturers. If now, Sir, as your correspondent suggests, he had by a comparison between the German telephones at the workhouse and the cheap form of British instruments there come to a conclusion adverse to the British, surely this was the time to have said so, if only to refute my contention.

From first to last, however, this was not even hinted at, and much, no doubt, as 'Englishman" would like to hear our architect pronounce in favour of German telephones, I must, in justice to a public servant, say that it would be contrary to all my impressions if he were the class of man to adopt these suggestions at the eleventh hour, however alluring a means of meeting a difficulty, when there was ample opportunity and good cause to have done so before had it been his conviction.

In regard to the 10 per cent. difference in price between the English and German telephones, I fear that "Englishman" is also speaking "without his book." If he had had the opportunity of seeing my specification, he would have found that I guaranteed the prime cost to be "in the aggregate practically the same as the German telephones specified by the architect." What more obvious, then, than that a sacrifice had been made to emphasise the appeal to patriotism. That such should have been necessary, even had it been accepted, is to our shame.

In regard to the problem why a body constituted for the express purpose of relieving distress should have formed such a misconception of its duties to us who have appointed them, to the community at large, and to the artisan classes in particular, I would say that its solution does not lie in the direction of the fond hopes of "Englishman," but in the thoughtlessness and spirit of *laissez faire*, which, unfortunately for us, in these times especially, enter so much into our character as a nation.—Yours, etc.,

PATRIOTIC ENGLISHMAN.

SIR,—The letter of "Puzzled" in the *Electrical Engineer* of Nov. 11 raises a question of great importance to the welfare of the country. "Englishman's" argument in your issue of the 18th inst. is based on a deal of assumption. Architects are not and cannot expected to be experts in everything that is included in their contracts. I have known some of them specify goods of foreign make without any logical reason whatever. London and many of our large towns are at present in a stage of siege, there being innumerable agents of foreign manufacturers attacking these professional gentlemen by methods and efforts which can only be used by very few British manufacturers. Architects and consulting engineers often specify goods of foreign make without knowing they are made abroad, and because the manufacturer has an office or agent in London; sometimes they know the origin and specify the goods because they know of no British maker. Clients other than public bodies usually do not accept everything their architect tells them, but use their own judgment.

It is remarkable that the municipal authorities do not take up a more patriotic position with regard to placing their contracts for machinery. To me, a patriotic Briton, it is painful to see in many works and electric lighting stations foreign machinery of all kinds—pumps, steam, and exhaust valves and instruments—which have been specified and ordered when goods equally good and cheap can be supplied of British make. I have seen boiler-feed pumps of American manufacture with cast cranks and rods, which would not have been accepted by the consulting engineers if so made by a British manufacturer.

It is very surprising that any member of a municipal body will vote under any conditions whatever for the placing of a contract for the supply of foreign-made machinery. I know of municipal works which have a considerable quantity of foreign-made machinery for which the British manufacturer has never been asked to tender. It is unfortunate that, generally, the members of a municipal body are ignorant of machinery, but if they were as careful in placing contracts for machinery as they are in placing

Digitized by Google

tailoring or printing contracts, then there would be very little foreign machinery imported for municipal purposes.

Most municipalities impose conditions in their contracts with British manufacturers which cannot be imposed on the foreign manufacturer, and the cost of manufacture is sometimes increased owing to the imposition of these restrictions. The labour and trade unionist members of municipalities insist on these clauses and conditions being inserted, their object being to find work for more workmen. Why do they not vote for a clause prohibiting entirely the supply of goods of foreign manufacture? This would have far more effect in the direction desired. The "unemployed" question becomes more difficult to deal with every year. Are not the municipalities themselves much to blame for the bad condition of trade and employment, by their great expenditure in unnecessary undertakings, in increasing the burdens which both manufacturers and consumers have to bear? In the few cases when foreign-made goods are cheaper—and I believe there are only very few—would it not be good policy for a town to pay a little more for British-made goods, and cut down, by an equivalent amount, its expenditure on unnecessary undertakings?

If municipalities exercised more control over the specifications and placing of contracts, the trade of the country would be greatly improved because of the increased output. In the cases where British goods are dearer at present the cost of production would be lessened, and there would be still less reason to place orders abroad.

The Press of this country is often very much to blame in giving undue prominence to foreign manufactures. The Government departments are more patriotic than municipal bodies, as at times they take great pains to induce manufacturers to take up the manufacture of some article which is being made abroad. Electors should give this question the attention it deserves, and at election times impress on candidates its importance.—Yours, etc., LANCASTRIAN.

ELECTRICAL DRIVING FOR FACTORIES.

SIR,—As I am particularly interested in electrical driving for factories and workshops, I should feel much obliged if you could insert the following in your paper. I shall be fitting electric motors to several machines in a workshop, and I am desirous to know if there is any sound way of ascertaining the power required to drive various machines—*i.e.*: (1) planing machines; (2) lathes for wood or metal; (3) boring machines, etc; (4) emery wheels. Could any reader strengthen me in this subject, and also inform me if there is any book published which deals with this branch of the electrical industry.—Yours, etc.

A SUBSCRIBER.

[N.B.—Our correspondent will find a great deal of the information he requires in Mr. A. D. Williamson's paper entitled "Applications of Electricity in Engineering and Shipbuilding Works," read before the Institution of Electrical Engineers at the beginning of last year.—ED. *E. E.*]

SAPPHIRE SLABS.

SIR,—I should esteem it a favour if you could inform me who are the best *makers* of half-finished "sapphire slabs" and finished "cupped sapphires," as required for electrical meters. I understand that the most important centres of this industry are in Switzerland and Germany, and I should like to get into touch with reliable firms for this class of work. I should supply the "rough Ceylon sapphires" myself, and should expect to get the slabs and sapphires cut from the same "on commission."—Yours, etc.,

N. C. M.

PERSONAL.

Mr. J. D. Pember, A.M.I.E.E., electrical engineer and tramway manager to the Farnworth Urban District Council, has been appointed electrical engineer to the Dartford Urban District Council at a commencing salary of £250 per annum. There were 159 applicants.

Mr. C. Wyatt, of the County of London Electric Supply Company, has obtained the vacant position of assistant electrical engineer at the Croydon electricity works.

The Bury Corporation have decided to appoint Mr. Clough tramway manager at a salary of £250 a year.

LEGAL INTELLIGENCE.

TRAMWAY ACCIDENTS.

At Manchester Assizes, before Mr. Justice Walton and a special jury, an action for damages was brought against the Manchester Corporation by Mr J. Whiteley Jones, commercial traveller, of Fallowfield. Plaintiff was travelling on one of the Corporation cars, when, on reaching Fallowfield, the driver over-shot one of the loops, and the car ran on till it went on the main line again, and there was a risk of its colliding with another car travelling in the opposite direction. No collision, however, occurred. In attempting to regain the loop the trolley got entangled with one of the span wires. The effect of this was to snap off the shaft of the trolley pole, and it fell, striking the plaintiff on the head. His injury was dressed by a local surgeon, and ultimately he returned home. He had suffered intense pain ever since, and his condition now was so serious that it was impossible for him to appear in court. He was suffering from traumatic hysteria, and there were symptoms of paralysis. The Corporation admitted liability.

Medical experts on both sides differed as to the extent of plaintiff's injuries and as to the time which would elapse before he could recover. The plaintiff's salary was £2 10s. a week, with £1 a day for travelling expenses. A considerable bill had already been incurred for medical attendance and special nursing, and it was intimated that the plaintiff had lost his situation.

The jury found for the plaintiff, and awarded £790 damages. An application for stay of execution on the ground that the damages were excessive was adjourned.

On Saturday last, Mr. Justice Phillimore and a jury were engaged at the Manchester Assize Court in considering whether the Manchester Corporation were to blame for an accident which occurred in Palatine-road. The plaintiff was Margaret Jane Cropper, wife of Joseph Cropper, builder and joiner, Runcorn.

The Plaintiff deposed that she and her sister were asked by the timekeeper, "Are you ladies going by this car?" They answered "Yes," and they had just got on to the step of the car when the car gave a jerk forward, and Mrs. Cropper was flung into the road, injuring her head and back very much. She repudiated the suggestion that she and her sister were safely on the car when it started, and that in their alarm at finding that Mr. Cropper and the child were being left behind they got off the car as it was moving, and thereby brought the trouble upon themselves.

Corroborative evidence was given.

The evidence for the Corporation was to the effect that the ladies gave no heed to the question of the timekeeper, and that when they saw the car starting they sprang to the side and got on. Even then they would have been perfectly safe if, in their bewilderment at finding Mr. Cropper and the little girl not with them, they had not, despite the warning of the trolley boy, got off of their own accord.

The jury, after retiring to consider their verdict, found for the defendant Corporation.

At the Manchester Assizes on Saturday Mr. Justice Phillimore and a jury were occupied in hearing two actions against the Salford Corporation arising out of electric tramway accidents. Robert William Parker claimed damages for personal injuries sustained in a collision between a tramcar and his cart. The Corporation had compensated him for the damage done to the cart, but after the settlement he found that he was suffering from an incurable hernia, which he attributed to the effects of the accident. Parker is a seaman and holds a mate's certificate, but at the time of the accident, owing to lack of employment, he was engaged in business as a greengrocer. It was stated on his behalf that his complaint will incapacitate him permanently from following his occupation as a seaman or from doing any heavy work. The defence was that he was negligent in turning his cart into the way of the tramcar. After hearing the defence the jury returned a verdict for the plaintiff, and assessed the damages at £225.

In the second case, William Hickson, cab proprietor, claimed damages in respect of a collision between a tramcar and one of his cabs.

The Plaintiff deposed that he was sitting on the box seat of a cab which was being driven from his yard across the tramlines in The Crescent. On leaving the passage which leads from the yard on to The Crescent, he and the driver of the cab saw a tram approaching, but as it was some distance away they thought they had ample time to cross the lines. The tram came along at a high speed, however, and caught the rim of the back wheels of the cab with such force that the vehicle and the horse were thrown on to the footpath and overturned. The driver of the car did not slacken down or ring the gong when approaching, although the cab was carrying lights. The plaintiff and the cabdriver were thrown off the seat, and the plaintiff was jammed between the lock of the cab and the horse. He received a severe shock. Plaintiff therefore claimed damages for personal injuries and for the damage done to the horse and cab.

The Corporation denied that they were guilty of any negligence. As alternative pleas they contended that the plaintiff was guilty of contributory negligence, and that the damage was due to an unavoidable accident.

The Motorman stated emphatically that he both rang the gong and applied the brake, and his statement was corroborated by several of the passengers, who put the speed at which the car was travelling when the cab came in sight at six or eight miles an hour.

The jury found for the plaintiff, and awarded £250 damages, which the foreman explained was made up of £30 for out-of-pocket expenses and £20 as compensation for injuries.

Digitized by Google

TELEPHONE CHARGES.

In the City of London Court the National Telephone Company, Limited, sued Mr. Henry J. Barclay, 99, Dashwood House, E.C., for £18. 10s. for a year's subscription for the telephone. The defendant had had the telephone for five years, and his subscription, due in advance in July last, had not been paid. He said he had lost his secretaryships one by one, until he had had to give up the offices, and had no use of the telephone for the period for which he was sued.

Mr. H. H. Gaine, plaintiffs' counsel, said that the defendant should have given six months' notice, and the telephone would have been removed.

The **Defendant**: I gave no notice because I did not know I should not want it.

Mr. Gaine said the cost to the company for putting on a new subscriber was £40, as they had to obtain wayleaves and enter into annual obligations.

The **Defendant**: I do not think a wealthy corporation like the National Telephone Company ought to press such a case.

Mr. Gaine said he must insist upon the defendant performing his contract and paying. If the company listened to all the people who said "I cannot pay," they might as well give up business at once.

Judge Rentoul, K.C., thought it a case of very great hardship on the part of a great company like the National Telephone Company, and one that ought not to have been brought. He did not like it at all; but the law was the law, and he must give judgment for the plaintiffs, with costs.

TRAMWAY FARES.

At the Bradford City Police Court on Tuesday Dawson Clayton was summoned for failing to pay a tram fare. The prosecution was initiated under a by-law which provides that any person riding on a tramcar shall, before leaving the car, pay the proper fare whether it is demanded or not.

Defendant was detected leaving the car before the conductor had finished collecting the fares by a plain-clothes constable.

The Magistrate imposed a nominal fine, but intimated that future offences of the kind would be dealt with more severely.

COMPANIES' MEETINGS AND REPORTS

EASTERN EXTENSION TELEGRAPH.

Sir John Wolfe Barry presided over the sixty-second half-yearly meeting of the Eastern Extension, Australasia, and China Telegraph Company, Limited, whose report appeared in our issue of the 11th inst.

The **Chairman**, in moving the adoption of the report, stated that an agreement had been entered into with the French Government for the acquisition by the latter of the Tonquin cable, the subsidy arrangement having expired. The proposed conference in regard to the relations with the Pacific Cable Company had again been postponed, and the ratification of the agreement between the Company and the Australian Government remained in abeyance. Though the competition between the rival routes continued, the Company had succeeded in maintaining its position.

The report was adopted.

CAPE ELECTRIC TRAMS.

The eighth ordinary general meeting of the Cape Electric Tramways, Limited, was held on Wednesday at the offices of the Company, 1, London-wall-buildings, Colonel Sir Charles Euan-Smith, K.C.B., presiding.

In moving the adoption of the report and accounts (particulars of which appeared in our issue of the 11th inst.), the **Chairman** stated, in regard to the Camps Bay tramways, that the Company had ample time before their option (as to the purchase of this system) expired in 1906 to decide what would be best to do. It was at present too early to attempt to make any forecast as to the results of the Company's operations during the current year; but, as he foreshadowed last year, considerable expenditure had still to be faced before the entire track, which had been in use for 10 years, could be thoroughly renewed. They had also to face two items of fresh expenditure, due to their obligation under the new Income Tax Act that had been passed in Cape Colony, and also the increased mileage tax on the metropolitan tramways which would come into force, these two items aggregating about £8,000.

Mr. L Breitmeyer seconded the motion.

A discussion ensued in regard to the lease of the Camps Bay tramline.

Mr. Theophilus thought it would be a long time before that part of the line would be made to pay, particularly as there were no houses in the district.

Two shareholders deprecated the Camps Bay transaction, though one acknowledged that if the object was to avoid competition the move might be justified.

The **Chairman** explained that the option was taken at the time of the war, when there were plenty of people in Cape Town and traffics were good. When the time came for the final decision as to the option to purchase the line, the matter would be decided simply in the interests of the shareholders of the Cape Electric Tramways Company.

Mr. Breitmeyer went into details with regard to the arrangement of the lease, and said that he believed in five or six years the Camps Bay line would have a flourishing traffic.

The **Chairman** reminded the shareholders that in nine years they had received 77 per cent. in dividends, and he considered they had nothing to complain of as to the success of the Company.

ARON ELECTRICITY METER.

The accounts for the year ended Sept. 30, after providing for general charges, depreciation, and share of expenses and discount on the issue of debentures, show a net profit of £10,679. 19s. 1d., which will be applied as follows: to remove from the balance-sheet the trading loss of the year 1901-1902, £4,645. 1s. 9d.; set aside for the debenture sinking fund in accordance with the trust deed, £2,500; out of the balance of £3,534. 17s. 4d. the directors propose to pay 2½ per cent. on account of the preference dividend in arrear, absorbing £3,122. 8s.; carried forward, £412. 9s 4d.—total, £10,679. 19s. 1d. The directors are pleased that the favourable anticipations of last year have to a great extent been realised. The demand for meters continues to increase, especially in Germany, and the business in England has also assumed a brighter aspect. The additional factory buildings in Schweidnitz were completed early in the year, and the facilities thus obtained have considerably helped to improve the results of the year's trading. The new alternating-current motor meter was placed on the market some time back, and appears to meet with general favour. The demand for the double tariff meter, the time switch, and other recent inventions is constantly increasing, and Prof. Aron, who is mainly responsible for their effective design and construction, continues to devote his attention to the development of all requirements connected therewith. Two of the directors—Sir James Pender, Bart., and Mr. Hugo Hirst—retire from office by rotation this year, but being eligible, offer themselves for re election. The directors much regret that, owing to business engagements, Mr. S. J. Blumlein was obliged to resign his position as director. Mr. Harry Kahn, a shareholder, has been elected in his place, and his appointment will require confirmation at the meeting.

GENEVA TRAMWAYS.

The report for the year ended Sept. 30 states that consequent upon the inability of the Compagnie Genevoise des Tramways Electriques to pay any dividend on its capital with which to meet this Company's indebtedness, the revenue account of the Company shows a loss for the period of £42,354, increasing the amount standing to the debit of revenue account to £117,288, mainly the result of the accumulation of unpaid interest on the debenture issues.

NEW COMPANIES REGISTERED.

Traction Corporation, Limited.—Capital, £100. Objects: to acquire any patents and rights relating to the production, treatment, storage, and use of any motive or mechanical power, and any apparatus therefor, and to carry on the business of manufacturers of and dealers in tramcars, carriages, motorcars, etc.

Immisch Launch and Boat Company, Limited.—Capital, £10,000. Objects: to acquire from the Immisch Electric Launch Company, Limited, their electric launches, boats, charging stations, property, and undertaking, and to carry on the business of electrical and mechanical engineers, electricians, contractors, etc. Registered office: Donington House, Norfolk-street, W.C.

British Electric Equipment Company, Limited.—Capital, £40,000. Objects; to adopt an agreement with H. G. Nicholson relating to the acquisition by this company of the business now carried on as the British Electric Equipment Company; to construct, etc., or acquire railways, electrical and other tramways, telegraphs, telephones, and other public works and conveniences in England or elsewhere; and to carry on the business of engineers, electricians, suppliers of electricity, rolling-stock manufacturers, makers of cables, wires, lines, accumulators, and lamps, etc. Registered office: 11, Queen Victoria-street, E.C.

Liens Registered.

Dewey Lighting Syndicate, Limited, Birmingham.—Lien registered Nov. 9 for £1,000 4 per cent. debentures. Holder: L. Barouche, 3, Norfolk-road, Edgbaston. Charged on the undertaking and all the property, present and future, including the uncalled capital for the time being, but excluding all patents in and for countries other than England.

Keynsham Electric Light and Power Company, Limited, Bristol.—Lien registered Nov. 14 for £300 5 per cent debentures, part of £1,500. Amount previously issued, £1,200. No trustees. Charged on the undertaking and all the property, present and future, including the uncalled capital.

Notting Hill Electric Lighting Company, Limited, London, W.—Trust deed registered Nov. 16 for £50 000 debenture stock, supplemental and in addition to trust deeds dated July 12, 1900, and Nov. 18, 1902, for securing £150,000 debenture stock. Charged on the freehold station for generating electrical energy belonging to the company jointly with the Kensington and Knightsbridge Electric Lighting Company, Limited.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Porto Alegre (Brazil).—The term for receiving tenders for an electricity station, already announced, has been prolonged to Nov. 30.

Cheltenham.—The Corporation invite tenders for the supply of a traction storage battery. Tenders by Nov. 30. See advertisement.

Digitized by Google

Pola de Siero.—The Municipality require tenders for the electric lighting for 10 years. Tenders by Nov. 30 to the Alcalde, Pola de Siero, Spain.

Madrid.—The General Telegraph Office require tenders for installation and working telephones in the town of Talavera. Tenders to above by Dec. 7.

Guirgia (Roumania)—Tenders are required for the electric lighting of the town. Particulars from the town's secretary. Tenders by Jan. 28 1905.

Kilmarnock.—The Corporation are prepared to receive tenders for the sole right of advertising on their tramcars. Tenders by Dec. 6. See advertisement.

Salamanca.—The Municipality require tenders for public electric lighting of the town. Tenders by Dec. 12 to above or to Direccion-General de Administracion, Madrid.

Edinburgh.—The Corporation invite tenders for the electric lighting installation at the branch free library, Morningside-road, Edinburgh. Tenders by Dec. 14. See advertisement.

Erith.—The Urban District Council invite tenders for motorcars, trucks, motors, and equipments, track sweeping and watering car. Tenders by Dec. 19. See advertisement.

Swansea.—The Corporation invite tenders for a 12 months' supply and delivery of motors and starting switches. Tenders by Dec. 1 to Mr. Jno. Thomas, town clerk. See advertisement.

Madrid.—The Public Works Branch of the Department for Agriculture require tenders for construction and working of an electric tramway between Azeritia and Zumaya. Tenders by Dec 10.

Caen (France).—The Prefect requires tenders for concession of a tramway from Ryes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1, 1905.

Llandilo (Wales).—The Urban District Council invite tenders for testing and calibrating the electricity meters installed in the town (70 in number). Tenders to Mr. R. Shipley Lewis, clerk, Llandilo, before Dec. 6.

St. Marylebone.—The Council invite tenders for the purchase of 1,000 house transformers, of from 1 to 5 kw. capacity together with a quantity of scrap cable and old cut-outs. Tenders by Dec. 5. See advertisement.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

London, S.E.—Tenders are invited for the erection of an electrical traveller to lift 12 tons over a span of 40 t. Persons desirous of tendering should send their names on or before Dec. 10 to B. E. Nightingale, Albert Works, Albert-embankment, Lambeth, S.E.

Johannesburg.—The Municipal Council invite tenders for two 35-ton electric overhead travelling cranes and transformer pillars and switchgear. Tenders must be addressed to Messrs. Mordey and Dawbarn, 84, Victoria-street, Westminster, S.W., and received by them not later than Dec. 27.

Glasgow.—The Governors of the Glasgow and West of Scotland Technical College invite tenders for a complete wiring installation and switchboards for the electric lighting of their new buildings. Specification may be obtained from Mr. H. F. Stockdale, secretary and director, 38, Bath-street, Glasgow, to whom tenders must be delivered by Nov. 26.

Stockport.—The Guardians invite tenders for providing and fixing electric light (wiring only), telephones, and bells required at the new infirmary, Stepping Hill. Plans and specification may be seen and all other information obtained from Mr. W. H. Ward, architect, Paradise-street, Birmingham. Tenders to Mr. Charles F. Johnson, clerk, and to be delivered by 10 a.m. on Dec. 12.

Brussels.—Tenders are invited for the construction of an electric generating station and other works in connection with the establishment of a goods station at Brussels. The estimated cost of the work is about £4,367. A deposit of about £280 is required to qualify any tender. Specifications (price 1s. 10d.) and further particulars may be obtained from M. De Rudder, Administrateur des Voies et Travaux, 11, Rue de Louvain, Brussels.

Perth (Australia).—Tenders are invited by the Deputy-Postmaster-General for the supply of the following telephone material; 19½ miles 26-pair lead-covered cable, dry core, to standard specification No. 7; 5,000 paper sleeves, 3in. long by $\frac{1}{16}$in. diameter; 350 yards paper stripe, 2in. wide. Conditions, etc., may be obtained at the General Post Offices at Perth, Adelaide, Melbourne, Sydney, Brisbane, and Hobart. Tenders by Dec. 28.

Withington.—The Guardians of Chorlton Union require tenders for electric lighting of old nurses' home, Withington Workhouse. Specifications, etc., can be obtained from the consulting electrical engineer, Mr. G. R. Peers, A.M.I.E.E., 16, John Dalton-street, Manchester (£1. 1s.). Tenders, endorsed "Electric Lighting, Nurses' Home," to be delivered to Mr. David S. Bloomfield, clerk, Union Offices, All Saints', Manchester, by 12 noon on 29th inst.

Shanghai.—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, London, E.C. Tenders by March 31.

Sydney.—Tenders will be received at the office of the Acting Deputy Postmaster-General, Sydney, New South Wales, up to 2.30 p.m. on Dec. 28, for the supply and delivery at the Departmental Stores, Sydney, of telegraph, telephone, and electric light material. Specifications and general conditions may be seen and tender forms obtained at the General Post Offices Sydney Melbourne, Brisbane, Adelaide, Hobart, and Perth. Samples may also be seen at Sydney, Melbourne, Brisbane, and Adelaide.

Bromsgrove (Worcs.).—The Visiting Committee invite tenders for the supply and erection at their new lunatic asylum of the following plant: (Section A) engines, dynamos, booster, and steam services; (B) storage battery and accessories; (C) main switchboard, ring main, feeders, distribution boards, wiring, lamps, and accessories. Specification, etc., may be obtained from Mr. Robert J. Oliver, clerk of the Visiting Committee, Shirehall, Worcester, on payment of £5 for each section of the work as above, which will be returned on receipt of a bona fide tender.

Leith.—The Corporation invite tenders for the supply of the following tramway cars, delivered free at Leith: Passenger cars—double-deck, single-truck cars with reversed staircases, equipped with motors, controllers, brakes, lifeguards, lights etc., complete; number, 30. Alternative tender for the same car with ordinary staircase. Double-deck, single-truck cars with reversed staircases and covered top, equipped complete as above; number, 7. Alternative tender for same covered-top car with ordinary staircase. Sprinkler car—sprinkler car with water-tank, sprinklers, grooved watering pipes, revolving brooms, snow-plough, with motors and all other necessary electrical equipment and brakes complete; number, 1. Conditions, etc., may be obtained from Mr. T. B. Laing, town clerk, Council-chambers, Leith, on payment of a deposit of £1. 1s., which will be returned on receipt of a bona fide offer. Tenders by Nov. 26.

Brisbane.—Tenders are invited by the Deputy Postmaster-General for the supply and delivery at the Telegraph Office Yard, Thursday Island, of 100 tubular wrought-iron telegraph poles to Specification No. 11 and Schedule No. 51, and also for the supply and delivery at the cable tanks, Thursday Island, of three nauts of submarine cable to Commonwealth Specification No. 8 (Queensland, No. 22) and Schedule No. 50. Tenders by Dec. 12. They must state the time required for delivery; this time will be counted from the date of the notification of the acceptance of the tender. Specifications and forms of tender can be obtained at the General Post Offices, Sydney, Melbourne, Brisbane and Adelaide. Neither the lowest nor any tender will necessarily be accepted. Tenderers are required to note that Customs' duties must be included in all charges, as per clause 2 of the general conditions. All tenders sent by post must be registered.

RESULTS OF TENDERS.

Brussels.—The Corporation have accepted the tender of Messrs. W. F. Jones and Co., of 50 Cannon-street, E.C., for 2,500 cable connectors, with special pilot-wire terminals.

Ballinasloe (Ireland).—The Committee of the District Lunatic Asylum have received the following tenders for wiring the temporary buildings for 35 incandescent lamps of 16 c.p. each, at a pressure of 200 volts, and the necessary overhead cables to connect same with engine-house, and all else necessary:

J. Dowdall and Sons, Dublin (accepted)	£53 10 0
National Electrical Company, Dublin	75 0 0
Taylor-Smith Electrical Company Dublin	74 0 0
Ampere Electrical Company, Dublin	40 0 0
Mansfield and Meldon, Dublin	62 15 0

London County Council.—The following tenders have been received for wiring the new fire station at Kensington:

Donnison, Sillem, and Co., 116, Great Portland street, W.*	£176 10 0
W. H. Johnson, 200, Upper Kennington-lane, S.E.	183 15 0
F. J. Coleby and Co., 7, Thayer-street, Manchester-square, W.	189 10 0
A. H. Marshall and Co., Limited, 270, High-road, Leytonstone	189 10 0
Durrell and Co., 58, Fenchurch-street, E.C.	189 13 0
O. Clark and Co., St. Mark's-road, North Kensington, W.	205 0 0
National Electric Construction Company, Limited, 34, Victoria-street, S.W.	213 0 0
L. Sunderland and Co., 39, Victoria-street, S.W.	215 0 0

* Recommended for acceptance.

APPOINTMENTS VACANT.

Pupil in company's light and power station. See advertisement.

Assistant Electrical Engineer, Worksop Urban District Council. Salary, £150 per annum.

Senior Operator, Glasgow Telephone Department. Applications by Dec. 5. See advertisement.

Engineering Apprentice, Gilbert Little and Sons, Limited, Smethwick. See advertisement.

Draughtsman, Electrical Department of the Admiralty. Applications by Dec. 5. See advertisement.

Switchboard Electrician, Glasgow Telephone Department. Applications by Dec. 5. See advertisement.

Shift Engineer, Battersea Borough Council. Salary, £104 per annum. Particulars and forms from Town Clerk. Applications by Nov. 29.

Demonstrator in Engineering, London County Council Paddington Technical Institute. Applications by Nov. 23. See advertisement in previous issue.

Chief Electrical Engineer and Manager, Leigh Corporation. Salary, £250 per annum, rising—subject to approved service—by annual increments of £20 per annum to a maximum of £350. Applications by Nov. 29. See advertisement.

BUSINESS NOTES.

TRACTION.

Keighley.—The Town Council have passed a resolution empowering the Tramways and Electricity Committee to fix or vary tramway fares.

Southampton.—The Tramways Committee are likely to advertise for a properly qualified general manager of the tramways undertaking in a few days.

Dover.—The Corporation have decided to extend the electric tramways to the suburb of River at a cost of £21,000, the work to be done by the unemployed.

Geneva Tramways Co.—The traffic receipts for the month of October, 1904, were £7,806. 14s., showing an increase of £287 as compared with the same period of 1903.

Rawtenstall.—The Town Council are bringing pressure to bear on the Rossendale Valley Tramways Company to make them proceed with the work authorised under their Act of 1902.

Greenock.—At a meeting of the Corporation it was agreed to increase the electrical energy supplied to the tramway company from 500,000 to 600,000 units per annum, the company to pay for the additional 100,000 at 1½d. per unit.

Rowley.—The electric tramways have commenced running upon the new line which has been constructed by the Rowley District Council from Old Hill to Blackheath at a cost of £32,000. The official sanction has been received from the Board of Trade.

Llanelly.—The dispute over the Llanelly tramways, it is rumoured, is settled, and there are indications that matters are now really progressing for the abandonment of the ancient tramcars at Llanelly, and that a system of electric light and traction cannot be much longer delayed.

Metropolitan Railway.—A trial run, which is stated to have been satisfactory, has been made from Neasden power-house to Uxbridge, and it is reported that the line between the latter place and Baker-street will be opened for traffic on Jan. 1. It has been decided to have two classes, and 1d. fares will be retained.

Swansea.—The important section of the Swansea Corporation tramway extensions—the line to Brynhyfryd and Pentre Estyll—has now been joined at the top of Llangyfelach-road, near Zoar Chapel. It opens out a teeming industrial district, which had hitherto been unprovided for in the way of transit facilities.

Dundalk.—The Privy Council have granted an extension of two years for the completion of the tramways authorised by the Dundalk Electric Tramways Order, 1897. Mr. Healy, K.C., for the promoters, intimated that the condition of the money market had hindered the undertaking, but there would be no further delay.

Metropolitan Electric Tramways.—The traffic receipts for the week ending Nov. 18, 1904, with 10 miles open, were £1,589 as compared with 8½ miles and £1,046 in the corresponding week last year, making an increase of £543. The aggregate this half-year is £37,980, against £27,576 in the corresponding period last year, or an increase of £10,404.

The Snowstorms.—Reports from nearly all the large towns in the Midlands and the North show that the recent snowstorms have interfered largely with the electric tramway services. The delays have been mostly due to the mechanical obstruction of the snow drifts. Snow-ploughs quite capable of dealing with ordinary falls had difficulty in coping with the drifting snow.

Cardiff.—On Thursday last Major Druitt, R.E., from the Board of Trade, inspected the tramway extensions at Cathays and Canton, and probably these will be opened to the general public within a week. The extension at Cathays is from the terminus near the Board schools in Orwys-road to Talygarn-street, some distance beyond the barracks. In Canton the extension is from Clive-road to a point beyond Victoria Park.

Worcester.—The City Council were asked at the last meeting to bring pressure to bear on the tramway company in order to obtain the extension of the tramways from the present terminus at Bransford-road to the city boundary on the Malvern-road. The inhabitants in that part are very numerous, and they feel they were deprived of something they were really entitled to. The matter was referred to the Streets Committee.

Morecambe.—At the annual meeting of the Morecambe Tramways Company, the balance-sheet showed a balance to revenue account of £1,310 5s. 8d. The Chairman said negotiations were proceeding with the local authorities respecting the electrification of the trams, and it was hoped that before long the shareholders would be called together to consider some proposal. A dividend at the rate of 3½ per cent. was declared, carrying £340 to next account.

Johnstone.—The representatives of Mr. Murphy, proprietor of the Paisley and District Tramway Company, have had a conference with the magistrates and Town Council of Johnstone to try and adjust some matters connected with the extension of the system to the boundary of the burgh. It was stated at the meeting that Mr. Murphy will apply for an order to authorise the construction of a tramway from Kilbarchan to join the Johnstone line, and thus give not only the west end of Johnstone but also Milliken Park and Kilbarchan districts tramway facilities.

Tube Extensions—The Central London Railway are promoting a Bill in Parliament empowering them to make far-reaching additions to their system running from the Bank to Shepherd's Bush. The intention of the company is to extend their present route eastwards from the Bank to Liverpool-street Station, returning by loop and proceeding westwards *via* Ludgate-hill, Fleet-street, Strand, Piccadilly, and Knightsbridge-road to Hammersmith. From this terminus the line will curve up, to meet the present one at Shepherd's Bush. Stations will be placed at convenient points along the system, varying from a half to three-quarters of a mile apart.

Belfast.—On Friday last a meeting of the Tramways and Electricity Committee was held in the Council-chamber at 2.30 p.m. for the purpose of opening the tender for the tramway works. We understand that almost a hundred tenders were received for the different portions of the work in connection with the electrification of the system, and these were duly opened, initialled, and listed. These were referred to Messrs. Lacey, Sillar, and Leigh, the consulting engineers. A joint report from this firm, the city surveyor, the electrical engineer, and the tramway manager in regard to the tenders will be prepared, and will be presented to the committee at the earliest possible moment.

Stirling.—For some time past the Town Council has been considering proposals for taking over and electrifying either the whole or part of the Stirling and Bridge of Allan tramways. At the last meeting a letter was read from the tramway company offering a sale of the portion of the line from King-street to St Ninians for the sum of £5,000, together with a satisfactory arrangement and guarantee that the company will not be disturbed in the possession of the portion of their line between King-street and the burgh boundary at the bridge over the Forth. The electrical engineer was asked to report on the probable financial results of a tramway on the basis of the above conditions.

Brighton.—At the last meeting of the Corporation Alderman Carden referred to the tramway returns for October, and said that although there was a decrease in the number of passengers, the trams were paying better than they were last year. They had more than made up for the decrease by cutting down the service and running fewer trams. Last month, although the takings showed a decrease of £23, they made a profit of £35, and last year at this time they were losing money. He might also tell the Council that the balance-sheet for the half-year ending Sept. 30 would probably show a profit of over £3,000 on the half-year. It was true that was the best half-year, but so far they had not lost any of it.

The Lorain System.—A horse was killed at Wolverhampton the other day after a fall of snow, and its death is naturally put down to electricity. Mr. Shawfield, the Corporation electrical engineer, says the system is not responsible for the animal's death. The question that will have to be decided is whether the horse slipped owing to the frost and died from natural causes. When the ground is frozen it may be difficult to decide whether the frost or the electrical current is responsible for accidents of this character. On the previous night a man fell down in Newhampton-road and suffered from the shock, but he was walking on the footpath, which was covered with frozen snow. Had he been in the tram track it might have been said that he also had been in contact with the electric current.

Proposed Railway.—The *Westminster Gazette* announces a scheme for an overhead electric railway from east to west above the Regent's Canal. The canal runs for 10¾ miles through a populous and busy commercial district from the East of London to Paddington. A *Westminster Gazette* representative interviewed one of the leading officials of the Regent's Canal and Dock Company, and learned that the scheme is undoubtedly contemplated. Although the canal company is not a promoter of it, it is aware of the details, and not averse to such a development of its property. The scheme it is stated, will not, if carried out, interfere with the waterway. As the route of the proposed line is open, it is pointed out that the cost of construction will be trifling compared with the outlay which would be necessary if lands, buildings, leases, etc., had to be acquired.

Burton.—The new top covers for the tramcars are much appreciated. They were supplied by Messrs. Milne, Voss, and Co., of Birkenhead. The roof runs from end to end of the car, and the portion of the upper deck which is enclosed is of precisely the same length, although a little narrower, as the inside. Sliding doors at each end are fitted, and along either side is a window, which can either be kept closed in very wet or windy weather, or let down altogether or partly lowered according to the nature of the elements. The windows, it should be pointed out, are entirely under the control of the conductor, and cannot be interfered with by the passengers. Under the canopy at the front and back of the car there is a curved seat for three passengers who prefer riding in the open, although at the same time they are protected overhead from the rain. The new arrangement will increase the accommodation of the car by two, seats being provided for 25 as against 23 passengers, this being due partly to the fact that additional space is provided by the removal of the trolley standard to the roof of the cover. The upper deck—or rather the enclosed part of it—will be lit by four electric lights, and, altogether, the interior presents a most cosy appearance. The design of the new covers is similar to those in use in Birmingham and Leeds, and they cost £82 each.

Liverpool.—Sir Charles Petrie, when thanking the Tramways Committee for re-electing him chairman, said that in the ensuing year some important matters would come before the committee, particularly in regard to the extension of the tramway system to the outer parts of the city, which work the Council empowered them some little time ago to apply to the Board of Trade for authority to carry out. There was also the question of the conveyance of parcels and merchandise which the committee would have to take into serious consideration. While the committee did not succeed in getting through all the extensions which were recommended to the Council, they did manage to get some, and before very long he thought the Council would come to see eye to eye with the committee, and give them the extensions they desired. He was one of those people who believed that they ought to have a belt of their tramway system right round the borough boundaries, and he felt certain a scheme of that sort would commend itself to the public. The traffic returns for the fortnight ended Nov. 12 showed that the receipts amounted to £20,485. 9s. 9d., an increase over the

Digitized by Google

corresponding period of last year of £422. 4s. 10½d.; the passengers carried numbered 4,442,552. an increase of 102,666; the mileage run 463 650, an increase of 5,862; and the number of cars in use 379, a decrease of 14.

Mansfield.—It is expected that the work of constructing the tramways in Mansfield will shortly be commenced. The Light Railway Sub-Committee of the Mansfield Town Council report that they had met a representative of the company, and had been over the route of railways in the borough, and, having been able to dispose of the objections of the Corporation, they recommended that such objections be withdrawn, subject to any electric cables being laid in a manner approved by the Council. At the last meeting of the Town Council it was resolved to authorise the committee, as soon as they were satisfied that the works were actually in progress, to order the additional generating plant necessary to supply energy to the company. It was also resolved to appoint Mr. R. Hammond, the consulting engineer, as arbitrator on behalf of the Corporation, and Mr. Harris on behalf of the tramway company, to fix terms on which the current was to be supplied to the company. Alderman Chadburn said the original contract for the supply of electrical energy included three sets of generating plant, but the order for one set was postponed owing to the delay in regard to the trams. The price of the set was £1,933. The company required the energy to be delivered to the car-shed situate on land near Radford-street, Stockwell-gate, and the cost of the necessary mains would be £2 150.

London County Council.—In reference to our note last week upon the Rosebery-avenue line, the Council have decided to enter into an agreement with the North Metropolitan Tramways Company, providing: "(1) That the tramways, authorised by the London County Tramways Act, 1900, in Rosebery-avenue, shall, when constructed for the underground conduit system of electrical traction, be worked by the company by horse traction pending the reconstruction, for electrical traction, of the tramways with which they will be connected; (2) that during the period that the new tramways are worked by horse traction the company shall pay to the Council a rent in respect of them equal to 8 per cent. per annum on the estimated cost—namely. £10,285—of their construction for horse traction, with the addition of £660 in respect of parliamentary, etc., expenses, making £10 945 in all; and (3) that when the new tramways shall be worked by electrical traction the amount by which the actual cost of constructing the tramways exceeds the sum of £10,285 above mentioned shall, for the purpose of calculating the rent provided for in the company's lease, be taken as the cost of reconstruction for electrical traction." The traffic from April 1 to Nov. 12 total £417,611, against £328,357 for the corresponding period of last year. At a recent meeting of the Bartholomew Club, the resolution in favour of trams over the bridges, following the reading of a paper by Mr. Carl Hentschel, C.C, was duly passed. The Council have purchased a site at Wandsworth for £4,500 on which to build a sub-station. The first consignment of top-covered cars has been placed on the Greenwich line. Others are expected to follow shortly. Systematic observations are to be taken of the earning capacity of the new type of cars.

LIGHTING AND GENERAL.

Enniscorthy.—A loan of £6,000 has been sanctioned for electric lighting at the lunatic asylum.

Armagh.—Mr. H. T. Harris is reporting upon the Urban District Council's proposed electric lighting scheme.

Clonmel.—Mr. Enright is about to report upon the proposed installation of electricity plant at the asylum.

Devonport.—An enquiry will be held on the 1st prox. into the application of the Borough Council to borrow £7,958 for the extension of the generating plant at the Corporation electricity works.

Electrical Trades Union.—It has been decided to form a branch at Hull. The London branch are holding a smoking concert on Dec. 10 and the Glasgow branch on Dec. 16, when non-members will be welcomed.

Bury.—The Electricity Committee on Thursday decided to obtain powers in the proposed Bill to borrow £30 000 for general electrical works, as the present equipment at the works is being used to its utmost capacity.

Dorchester.—The Dorchester and District Electric Supply Company, Limited, 11, Carteret-street, Westminster, intend to apply for a provisional order for the whole of the borough of Dorchester, in the county of Dorset.

Finchley.—The Electric Lighting Committee, in their last report, state that up to date 285 consumers have applied for 14 762 8-c.p. lamps. The capital expenditure to Sept. 30 was £32,145, and the balance unexpended £2 855.

Derbyshire and Nottinghamshire Electric Power Co.—A special meeting is to be held on the 30th inst. to sanction the issue of permanent debenture stock to a nominal amount of £100,000 to carry interest at the rate of £5 per cent. per annum.

Bradford.—The Corporation Electricity Committee have received a memorial from the Drapers' Association with respect to the scale of charges for illuminating purposes and have instructed the electrical engineer to prepare a report on the subject for the benefit of their customers.

Norwich.—It has been decided to reduce, from Jan. 1, the maximum price of current for lighting from 5d. to 4½d. per unit, which is a reduction of 10 per cent. The committee consider that they can safely do that, and not only pay their way, but put a substantial sum away for reserve.

Brighton.—Deputations from Portslade, Southwick, and Shoreham Councils have visited the large electric station now being built by the Corporation at Shoreham. The station borders the canal, and it is claimed that, notwithstanding its remoteness from coalfields, Brighton will be able to supply electricity at as low a price as is charged anywhere in the country.

Fulham.—A brick chimney shaft is to be erected at the electric lighting works at a total estimated cost of £4,000, and we understand that the borough surveyor has been instructed to have the concrete foundations carried out by direct labour under his supervision at an estimated cost of £2,250.

Dunfermline.—The Fife Power Company's generating station at Townhill is nearing completion, and an early application is expected to the Town Council for permission to open the roads and streets for the laying of cables The Dunfermline Abbey authorities have decided to adopt electric light in place of gas.

York.—A tender has been accepted for the installation of electric haulage plant at the works on Foss Islands in connection with the coal storage, at the sum of £735. By this means it is expected to save 6d. per ton on the coal. This would mean £125 a year, and the interest and sinking fund amount to less than £50.

Handsworth.—At last week's District Council meeting it was proposed that, in view of recent experiences in street-lighting of other local authorities, the Council reconsider the electrical engineer's report of May, 1903, and especially that part dealing with street-lighting by arc lamps. The motion was negatived by 15 to 3.

Portsmouth.—Eastney Barracks are to be fitted with the electric light. No less than 3 000 lamps will be required. It is anticipated that the Municipal Telephone Committee will within a few days be able to make the gratifying announcement that the undertaking has no fewer than 2 000 instruments fixed and working.

Ormskirk.—The Guardians are purchasing from Messrs. Guinness, of Dublin, electrical plant, including two engines, two dynamos, and certain instruments in connection with the switchboard. The plant has been in use seven years, and the Guardians are to pay one-third of the original cost. The machinery is stated to emanate from the best makers and to be in good condition.

Dover.—The Corporation intend to apply for a provisional order to authorise them to produce, store, supply, sell, and distribute electrical energy for public and private purposes within the parishes of Hougham, Poulton, River, Alkham, Ewell, Whitfield, West Langdon, East Langdon, St. Margarets-at-Cliffe, West Cliff, and Guston, in the rural district of Dover, in the county of Kent.

Buxton.—At the last Urban District Council meeting, upon an estimate for balancing apparatus being submitted, the engineer's suggestion that he should inspect the apparatus at work at Wolverhampton or elsewhere was approved. Inspection is to be made at the same time of hoisting gear and winch for lowering arc lamps, and a report on tenders received will be made to the next meeting.

Stock Exchange.—Applications have been made to the committee to appoint a special settling day in and to grant a quotation to Calcutta Electric Supply Corporation's further issue of 20,000 ordinary shares of £5 each (£3 paid), Nos. 60,001 to £80 000; and W. T. Henley's Telegraph Works' further issue of 5 000 4½ per cent. cumulative preference shares of £5 each (fully paid), Nos. 35,001 to 40,000.

Rawtenstall.—The Rawtenstall Branch Social Democratic Federation have forwarded to the Town Council a resolution condemning their action with regard to electric lighting arrangements, and recommending that the Council adopt a scheme to generate and distribute its own electricity, instead of buying in bulk from a power company. The letter will be dealt with at the same time as other matters of a kindred character when they are brought before the Electricity Committee.

Hemsworth.—The Hemsworth Electricity Supply Company, Limited, intend to apply for an electric lighting provisional order authorising them to supply electricity within the townships of Hemsworth, Wintersett, Ryhill, Havercroft, South Hiendley, Shafton, Brierley, South Kirkby, South Elmsall, North Elmsall, Upton, Badsworth, and Ackworth, within the rural district of Hemsworth. Messrs. R. J. Nicholson and Co., 26, Cannon-street, Manchester, are the company's engineers.

Agencies.—The Rhodes Electrical Manufacturing Company, Limited, have opened a branch office at Newcastle-on-Tyne, at 17, Eldon-square, under the management of Mr. Joseph P. Sleigh, late manager of the branch office of the British Thomson-Houston Company.—Mr. John Child, A.M.I.M.E., 108, Claremont-road, Liverpool, W., has been appointed sole representative in Great Britain for central condensing and cooling plant, oil separators, etc., manufactured by Messrs. Eugen Blasberg and Co., Düsseldorf.

Croydon.—The County of London Electric Supply Company, Limited, intend to apply for a provisional order to supply electricity, electrical energy, and power within the rural district of Croydon (Surrey), to construct works, to lay down wires and other apparatus, to break up streets therein, and to make agreements with local authorities. The repeal of the Mitcham Electric Lighting Order, 1901, and the transfer of right of purchase contained in the Wimbledon Electric Lighting (Extension) Order, 1903 are included in the application.

New Malden.—Last week's meeting of the District Council was specially convened, principally for the purpose of considering the Council's policy relative to the electric lighting provisional order. A resolution, "That an expert electrical engineer be appointed to inspect the district and give a report with reference to the provisional order, at a fee not exceeding 30 guineas" and a number of amendments were discussed in succession, and lost. Finally, notice of motion was given to rescind a previous resolution embodying a request to the committee not to act.

Kensington.—Applications from the Post Office for permission to lay pipes for telephone wires, etc., in Cromwell-place (east side) and Thurloe-place (centre), Old Brompton-road (south side), Lansdowne-road (west side), Beaufort-gardens (north-east side); notices from the

Digitized by Google

Brompton and Kensington Electricity Supply Company relative to proposed extensions of their mains, etc., in Earl's Court-road; and an application from the National Telephone Company for permission to lay a branch pipe from Queen's-road along Phœnix-place have been agreed to.

The Tariff Commission.—The Tariff Commission has held four meetings during the past fortnight at the Whitehall Rooms, under the chairmanship of Sir Robert Herbert, G.C.B., making 75 sittings to date. At the last four meetings evidence was taken in regard to the engineering, building, furniture, and textile trades. The witnesses examined in the engineering section were as follows: Mr. John McLaren (J. and H. McLaren, Midland Engine Works, Leeds, engineers); Mr. George Cradock (Geo. Cradock and Co., Wakefield, wire drawers and rollers).

Awards.—We are informed that the Westinghouse Companies' exhibits at the St. Louis Exposition have received a special award in the department of machinery for the best, most complete, and most attractive exhibit, and no less than 12 grand prizes and 25 ordinary awards. The gold medals were for complete alternating-current and direct-current switchboards, Bremer arc lamps and arc lighting system, Nernst lamps, Cooper Hewitt lamps for photo-engraving, water and gas meters, electric measuring instruments, and for industrial betterment work and housing of the working class.

Staff Dinner.—There was quite a large muster of local talent at the first staff dinner and smoking concert of the electricity department of the Stretford Urban District Council last Friday. Councillor S. Lawton (chairman of the Electricity Committee) presided, supported by Councillor T. Johnson, J.P. (chairman of the Council), Councillor Estcourt (vice-chairman, Electricity Committee), Councillor Fulford, Mr. G. H. Abrahams (clerk to the Urban District Council), and Mr. R. Rowland (resident engineer). The attendance, the speeches, and the songs testified to the greatest harmony existing within the department, and with the Council and district in general.

Blackpool.—Mr. C. Furness, the electrical engineer, in his last report states that the returns for October show an increase in the works output of 10,729 units, as compared with the corresponding month of last year, made up as follows: Private lighting: October, 1904, 116,909; October, 1903, 102,409—increase, 14 500. Public lighting: October, 1904, 22,746; October, 1903 20.601—increase, 2,145. Lytham and St. Annes trams: October, 1904, 6 540; October, 1903, 6,457—increase, 83. Corporation trams: October, 1904, 71,075; October, 1903, 77,074—decrease, 5,999. Totals for month: 1904, 217,270; 1903, 206,541—net increase, 10,729 units.

Electrical Shares.—It is reported that there is some abatement in competition in the electrical industry, due partially to the greater activity in trade in Germany, which has caused makers there to compete less keenly for orders in foreign markets. That German electrical manufacturers are well supplied with orders is evident by the last report of the Allgemeine Electricitäts-Gesellschaft, which has recently increased its dividend from 8 to 9 per cent., paying the larger rate on considerably increased capital. The company's turnover during the first three months of its new financial year shows an increase of nearly 50 per cent. compared with 1902-3. British manufacturers should now, therefore, have an opportunity of doing better.

Battersea.—The agreement entered into by the Council with the County of London Electric Supply Company, Limited, relative to the supply of electrical energy in areas transferred under the provisions of the London Electric Lighting Areas Act, 1904, has been confirmed by the Board of Trade, and the areas are to be transferred on Jan. 1, 1905. The works necessary to be carried out to enable the Council to supply in the transferred areas will be taken in hand, and are estimated to cost £5,900. If both schemes are carried out concurrently a large saving will be effected, inasmuch as the feeder cables, etc., would follow the same route for some considerable distance. The net amount to be paid to the company under the agreement in respect of consumers in the transferred areas is approximately £2600.

Kilkenny.—The Irish *Engineering Review* says: "At a recent meeting of the Urban Council a letter was submitted from the Local Government Board in response to the Council's enquiry if they could have a loan of £10 000 for electric lighting, that the Board were unable to sanction such a loan as the Corporation had made default in their supply of a water and sewerage system, and also that the Lords of his Majesty's Privy Council had ceased to make advances for electric lighting purposes After some discussion in the Council the matter dropped. At a further meeting of the Council, after a long discussion, it was proposed that the lighting of the city be offered to any local company which would be formed for 15 years at £400 per year, and that the question be adjourned for six weeks to see if such company could be formed."

Fireproofing.—We have received particulars from the Snowdon's Flame Preventers Company of the solutions which they are now supplying in quantity for fireproofing all kinds of flammable material. This they can do without injuring in any way the actual texture or colour of the material which is treated. The compositions used are water repellent, and, therefore, the articles become more or less damp-proofed. One of the solutions which is absolutely waterproof as well as flame resisting can be obtained, but this cannot be applied universally, as it affects the colour of the articles treated. Mr. Snowdon is also developing a flameless celluloid, which should be of great service to electrical engineers. It will be remembered that the Admiralty test all their insulating materials with flame before passing the same for construction in electrical apparatus.

Standard Metal Engraving Co.—This firm, which have their offices at 93 and 94, Chancery-lane, make a speciality of engraved name-plates, which they prepare by a special method. The result, from samples which have been shown to us, is most effective, and, what is much to the purpose nowadays, they are not expensive. The engraving is, we believe, done by chemical means by a patented process. These name-plates are well known, and have been adopted by a number of engineering firms. The same company also specialise in the construction of dials for electrical measuring instruments, which they can make suitable for voltmeters, ampere-meters, etc. We understand that the engraving can be done after calibration, and the result is exceedingly neat and effective. The dials are made in a variety of styles to suit the demands of purchasers of electrical instruments.

Cardiff.—The Finance Committee on Monday sanctioned the borrowing of £87 868 for extensions of the electric lighting and power plant, which has, as previously announced by us, already received the sanction of the Electric Lighting Committee. Mr. Ellis, in order to keep down the expenses of the town as far as possible, has decided not to put any more plant in for the present winter. The result is that both the Canton and the Roath stations are running up to their full capacity without any spare plant. Already the committee have had to give notice to contractors in the town that they cannot take further consumers for the present winter. The proposed new loan will cover the whole of their applications to the Local Government Board for the next two or three years. There are already contracts in hand for power equivalent to over 8,000 lamps. The town hall and law courts will require another 8 000 lamps. The Electricity Committee have borrowed altogether from the rates to pay their debts £11 000 from time to time. During the last two or three years the whole of this sum has been repaid, and £1,800 in addition has been placed to the credit of the rates. In two years nearly 60,000 lamps had been connected out of 110,000 during the past 10 years.

London Gazette.—The first meeting in the estate of Albert Smith, electrical engineer, lately trading as the Electrical Motor Supply Company, residing at 107, Exchange-road, West Bridgford, Notts, and lately trading at 54, Houndsgate, Nottingham, will be held at the Official Receiver's Offices, 4, Castle-place, Park-street, Nottingham, on Nov. 30 at 12.15 p.m. The last day for receiving proofs in the estate of William Wenham, electrical engineer, 5, Century-buildings, London-road, Croydon, is Dec. 5. A receiving order has been made out on creditor's petition in the estate of William Sumner, electrical engineer, 140, Dale-street, Liverpool. The first meeting in the estate of Henry Coles, electrical engineer, 10, York-street, Swansea, will be held at Bankruptcy-buildings, Carey-street, London, at 11.30 a.m. on Nov. 29. The first dividend of 6s. 6d. in the £ has been declared in the estate of Charles Aubrey Smith, electrician, 23, King-street, Regent-street, London. The partnership between Benjamin Reid and Arthur Fishlock, electrical engineers, 2A, Maryland-street, Liverpool, under the style of Reid and Fishlock, has been dissolved by mutual consent. The first meeting in the estate of Alfred James Hollington, electrical engineer, residing at Barclay Oval, Woodford Green, Essex, and employed at 93, St. Martin's-lane, Charing Cross, was held at Bankruptcy-buildings, Carey-street, London, at 12 noon on Nov. 23. An adjudication order has been made out *re* Arthur Edgar Brooks, electrical engineer, 110, Cheapside, London.

Colliery Plant.—Messrs. Ernest Scott and Mountain, Limited, of the Close Works, Newcastle-on-Tyne, report recent orders for electrical machinery for use in collieries, and amongst which we mention the following: (1) For the Bedminster Coal Company, Bristol, a complete installation in hand, consisting of a steam-engine of 300 h.p., together with generator, and a complete equipment of electric motors for driving the underground haulage, pumps, etc. In this contract the machinery throughout will be of the three-phase alternating-current type, as it is proposed at a later date to add considerably to the installation, and to drive the whole of the collieries under the control of the Bedminster Company from one central station, and as some of the pits are some distance away from this station, the utilisation of three-phase current will have great advantages, as the pressure can be readily increased for the long-distance circuits. (2) For the Whitwick Colliery, near Leicester, a three-throw horizontal pump, with electric motor, cables, etc., constructed to deliver 30 to 40 gallons per minute against a vertical head of 500ft. (3) Other plant is for one of the leading collieries in India, Messrs. North's Navigation Collieries, Limited, the Wallsend and Hebburn Coal Company, etc. Messrs. A. Hirst and Son, Limited, electrical engineers, Crescent Works, Dewsbury, have secured an order for an electric generating and haulage plant to be installed at the Wheldale Colliery, Castleford. The plant comprises a 150 kw. dynamo direct coupled to a high-speed vertical engine, two 60-h.p. motors and one 24-h.p., two hauling gears, and over three miles of cables.

Macclesfield.—Messrs. Foote and Milne, Limited, 66, Victoria-street, Westminster, intend to apply for a provisional order authorising them to produce, store, supply, sell, and distribute electricity for all public and private purposes in the borough. The terms offered to the Macclesfield Corporation provide that the powers to be contained in the order are only to be exercised by a company to be approved by the Board of Trade, and in which company residents in the area of supply shall be given the opportunity of subscribing not less than one-half of the capital to be issued on the company going to allotment. The Corporation will have the right to requisition the company to lay down distributing mains for the purpose of a general supply throughout any street or part of a street in which the Corporation have the control and management of the public lamps, but such requisition is not to be binding upon the company unless the Corporation give a written undertaking at the time of service to take a supply of energy for lighting the public lamps in such street or part of a street for a period of not less than three years, and it shall not be binding upon the company to supply energy to public lamps outside the compulsory area named in the order unless such public lamps be placed at intervals of not more than 75 yards from each other, or from any existing distributing main of the company. The Corporation will, further, have the right to purchase the undertaking at any time after 10 years from the date of the completion of the works upon giving one year's notice in writing, at valuation as a going concern. In default of agreement the price is to be settled by arbitration under the provisions of the Arbitration Act, 1889.

PROVISIONAL PATENTS, 1904.

Nov. 14.

24599. Improvements in guards or shields applicable for electric incandescent lamps. John Devitt and Charles Maskrey, 6, Bank-street, Manchester.

24605. Improvements in or relating to wattmeters. William Edward Sumpner, St. John's House, Sevenoaks, Kent.

24616. X-ray obstructing material. William Morley Martin, 16, Penryn-street, Redruth, Cornwall.

24620. Electric clocks and the like. Isaac Hardy Parsons and Alfred Ernest Joseph Ball, St. Elmo, Woodland-avenue, Stoneygate, Leicester.

24627. Improvements in subscriber's call signalling devices for telephone exchange systems. John Macfee, 65, Chancery-lane, London.

24632. Improvements in electrically-operated switches. August Eckstein and Edwin Parker, Peel Works, Adelphi, Salford, Manchester.

24660. Improvements in gas and electric lamps or fittings. George Arthur Walker, 7, Staple-inn, London.

24663. Improvements in electrical valve-controlling systems. Isaac George Waterman, 111, Hatton-garden, London. (Complete specification.)

24675. Improvements in electric brakes for trams and other vehicles. Robert Bolton Ransford, 24 Southampton-buildings, Chancery-lane, London. (The American Electric Brake Company, United States.) (Complete specification.)

24689. Improvements in and relating to electric storage batteries. Louis Nestor Joseph Roselle, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Nov. 16, 1903, being date of application in France.) (Complete specification.)

24692. Improvements in means for ascertaining the power factor in alternating-current systems. Alexandre Grammont, 18, Buckingham-street, Strand, London. (Date applied for under Patents Act, 1901, Nov. 24 1903, being date of application in France.) (Complete specification.)

24698. Improvements in electric switches. (The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24699. Improvements in electric motor control and apparatus therefor. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24700. Improvements in systems of electric motor control and in apparatus therefor. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24701. Improvements in electric motor control and in apparatus therefor. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Nov. 15.

24708. Improvements in the control of electrically-propelled vehicles. Charles William Godson Little, 99, Albemarle-road, Beckenham, Kent.

24710. Improvements in or connected with coin-freed games of skill and apparatus for administering electric current. John Henry Gibb, 58, St. Vincent street, Glasgow.

24715. Improvements in incandescent gas and electric globe lamps. John Westwood Lea and John Hall Perrins, Midland Works, Bracebridge-street, Birmingham. (Complete specification.)

24722. Improvements in electric tramcars and the like, and in lifeguards or obstruction removers for use therewith. William Whittaker, 254, Colne-road, Burnley. (Complete specification.)

24744. Electrical timekeeper and alarm clock. Hermann Ferdinand Schmidt, 135, East-road, City-road, London.

24769. Improvements in or connected with electrical commutators. Nalder Bros. and Thompson, Limited, Francis Henry Nalder, and Oswald Cox, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

24770. Improvements in electric signalling devices for elevators or the like. Oliver Imray, Birkbeck Bank-chambers, Chancery-lane, London. (Fred S. Payne, United States.) (Complete specification.)

24788. Improvements in electric arc lamps. Willis Rodney Whitney, 83 Cannon-street, London. (Date applied for under Patents Act, 1901, Nov. 16, 1903, being date of application in United States.) (Complete specification.)

Nov 16.

24828. Improvements in apparatus for raising and lowering electric arc lamps. William Frederick Mason, 64, Barton-arcade, Manchester.

24831. Improvements in apparatus for actuating the points in electric tramway systems. Ernest Rothwell, 17, St. Ann's-square, Manchester.

24874. Improvements in and relating to alternating-current electric generators. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24850. Improvements in instruments for detecting and measuring alternating electric currents. John Ambrose Fleming, University College, Gower street, London.

24857. Improvements in electricity meters. Charles Alfred Adolph Capito, 5, Eardley-crescent, South Kensington, London.

24873. Improvements in or connected with regulating arc lamps. James Brockie, 33, Chancery-lane, London.

24875. Improvements in controlling apparatus for electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24876. Improvements in and relating to electromagnetic speed-changing and reversing devices. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24900. Improvements in electric breaks or interrupters, and means for operating the same. Albert Lewis Davis, 70, Chancery-lane, London.

24915. Improvements in or relating to methods of insulating coils and the like, especially applicable to the construction of high-tension electrical machinery. John Somerville Highfield, 322, High Holborn, London.

Nov. 17.

24918. Improvements in the manufacture of leading-in wires for incandescent electric lamps or other vessels requiring leading-in wires with gas-tight joints. Augustus Charles Hyde, 7, Crown Office-row, Inner Temple, London.

24927. Switches for electric railways and tramways. Arthur Marshall, 38, Sunninghill-terrace, Loampit-hill, Lewisham, London.

24951. A new or improved medical electric and magnetic appliance. Tom Cooke and John Robert Cooke, 111, Hatton-garden, London. (Complete specification.)

24955. Improved ironing machine with electrically-controlled pressure. Albert Ernest Hacking and John Pycroft, 11, Burlington-chambers, New-street, Birmingham.

25010. Improved process for producing nitric acid by aid of electricity. Westdeutsche Thomasphosphat-Werke Gesellschaft mit Beschränkter Haftung, 322, High Holborn, London. (Date applied for under Patents Act, 1901, Oct. 19 1904, being date of application in Germany.) (Complete specification.)

25026. Improvements in and relating to electric switch-operating mechanism. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25027. Improvements in and relating to electric switch-operating mechanism. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Nov. 18.

25029. Improvements in potentiometer apparatus for localising the position of faults in electric wires and cables. Trubie Moore, Park-crescent, Roundhay, Leeds.

25041. Improvement in trolley heads in connection with electrical tramways on the overhead wire system. William Kneen, 11, Euston-road, London.

25072. Improvements in terminals for use in electric main and other switches. John Richardson Craig, jun., 25, Renfield-street, Glasgow.

25078. Improvements in electric ignition devices. Eugen Aron, trading as the Continental Hardware and Cycle Company, 61, Fore street, London. (Louis Boulez, France.) (Complete specification.)

25095. Improvements in electric accumulators. Ernst Waldemar Jungner, 18 Buckingham-street, Strand, London. (Complete specification.)

25105. Improved device for distinguishing between the poles of an electric circuit. Henry George Prested, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

25106. Improved apparatus for regulating the current through an electric lighting circuit. Henry George Prested, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

25112. Improvements relating to electric light systems. Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (Charles Albert Gould, United States.) (Complete specification.)

25114. Improvements in electric accumulators. Jacques Marie de la Croix and Henry Francis Joel, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

25128. An improved fireproof, acid-proof, and electrically insulating material. U. Marga, 322, High Holborn, London. (Complete specification.)

25129. Improvements in electric braking apparatus. William Phillips Thompson, 6, Lord-street, Liverpool. (Levi Stamm and Edward Dudley Lewis, United States.) (Complete specification.)

Nov. 19.

25172. Improvements in dynamo-electric machinery. Samuel Thompson Webster, 34, Castle-street, Liverpool.

Digitized by Google

25171. Improvements in electric light baths and the like radiant therapeutic appliances. John Scott, 34, Castle-street, Liverpool.

25175. Improved electrical apparatus for timing the speed of motorcars or other vehicles over measured distances. Gerald Higginbotham, 4, St. Ann's-square, Manchester.

25181. An improvement in and relating to electric lamps. Charles Patrick Joseph Fitzsimon, 30, Lower Ormond-quay, Dublin.

25189. An improved composition for electrical conduits. Robert Starke, 195, Upper Thames-street, London.

25191. Application of a coherer to any electric transmission by means of conductors for any distance, for telegraphic, telephonic, signalling, bell, or other systems. Giuseppe Magini, 52, Chancery-lane, London.

25196. Improvements in means for improving the power factor of alternating-current circuits. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25218. An enclosed electromagnet. David Perret, 40, Chancery-lane, London. (Date applied for under Patents Act, 1901, March 12, 1904, being date of application in Switzerland.) (Complete specification.)

25219. Improvements in protective systems for electric distribution lines. Leonard Wilson, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Nov. 20, 1903, being date of application in United States.) (Complete specification.)

25220. Improvements in protective systems for electric distribution lines. Leonard Wilson, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Nov. 20, 1903, being date of application in United States.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 8, 1904.

1903.

22423. Electric generators and motors. Hindle.

23465. Safety devices for alternating-current electric distribution systems. British Thomson-Houston Company, Limited, Clinker, Wedmore, and Whitcher.

24847. Electro-mechanical automatic switches for surface contacts for electric tramways and railways, also applicable for automatic signalling on railways and tramways, and for other similar purposes. Matthew George Waggott, Michael Rosenberg, and William Smyth.

24864. Electrical clocks. Chandler and Bonniksen.

24912. Apparatus for utilising electrical energy, particularly applicable for cigar lighters and such like purposes. Ayer.

25122. Electric arc lamps. Fournier.

25146. Controllers for electric motors. Laird and Todd.

25236. Apparatus for commuting electric currents passing through combined arc lamp and incandescent lamp circuits. Smart.

25282. Telegraphic signalling keys. Fleming and Marconi's Wireless Telegraph Company, Limited.

25283. Transmitting instruments for wireless telegraphy. Fleming and Marconi's Wireless Telegraph Company, Limited.

25298. Bodies adapted for lighting purposes, and rendered incandescent by heat or electricity. Ladd.

26963. Suspension of magnetic compasses and other instruments. Lilley.

27497. Devices for lighting gas burners by electricity. Duckham.

28324. Automatic weigher for grain, coal, or other flowing materials electrically controlled. Simeon, Parnall, and Hipkins.

1904.

214. Electric batteries. Kamperdyk.

574. Construction of the armatures of dynamo-electric machines and electric motors with a view to facilitate the mounting of the same upon their shafts. Rees.

623. Electric incandescent lamps. Schwab and Vogel.

1011. Electric winches. Laing.

$\frac{1}{2}$in., and there are the usual two tool boxes. This planer works on the edge of a deep pit so that work up to about 18ft. by 18ft. by 4ft. can be taken. In addition to these large planers are a number of smaller planing machines, mostly by the Niles Tool Company. A little further down the shop from the two large planers comes the largest boring mill at present installed. This is a horizontal mill, and will take work up to 19ft. 6in. diameter. This mill was manufactured by Messrs. Smith and Coventry, and works at 12 different speeds, the feed being from $\frac{1}{32}$in. to $\frac{5}{8}$in., and there being two tool boxes on the cross slide. Near this machine the foundations have been provided for a larger boring-mill, which will take up to about 30ft. diameter, now in course of construction. All these larger tools have individual motors, so that there is no waste in heavy belting or countershafts, nor in the motor when the machine is idle. It will also be seen from Fig. 8 that these larger machine tools are served by the two-ton jib cranes referred to above. In consequence of this the work can be adjusted without requiring the presence of the main travelling cranes over the tools. This leaves the travellers free to move materials up and down the shop, which is their real purpose, and it avoids endless delays. There are also a large number of smaller horizontal boring machines

FIG. 12.—View of the North Gallery where the Field Coil Winding is carried out.

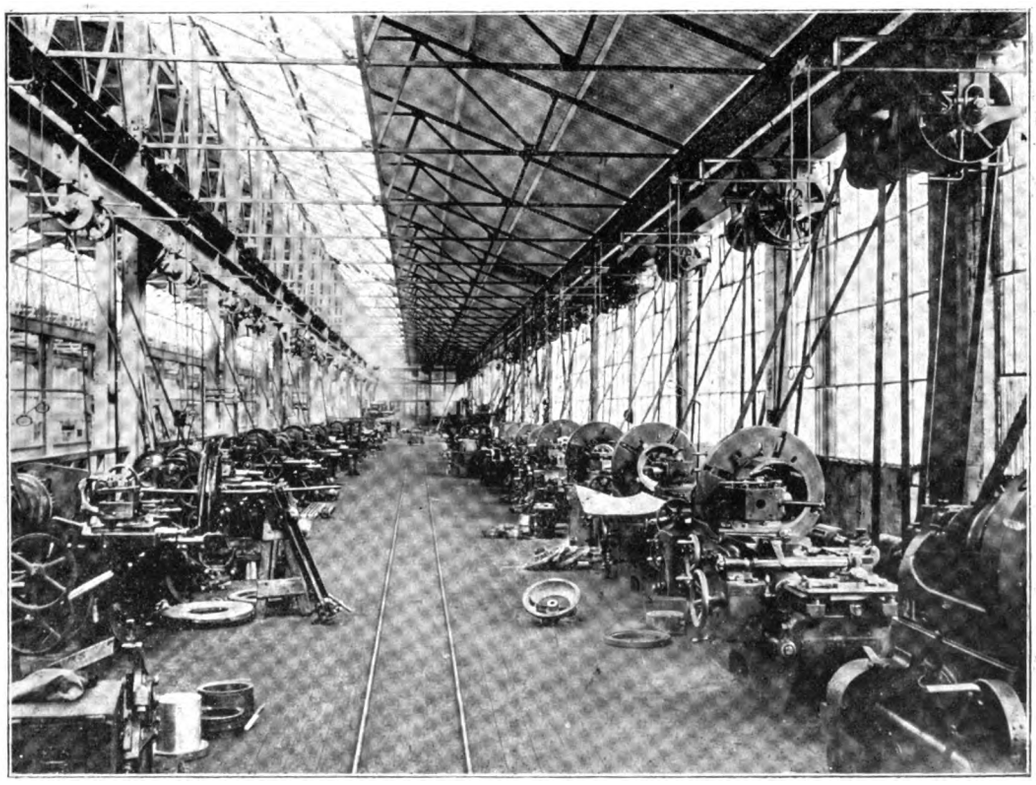

FIG. 13.—South Gallery, equipped with Turret and Capstan Lathes for Machining Motor Parts and general Repetition Work.

Digitized by Google

in the shop, the smallest of these having a 3ft. bed, as it is found that a great many classes of work can be done much more expeditiously on these mills than on ordinary horizontal lathes. The majority of the smaller boring mills are by Messrs. Richards.

Farther down the shop is the erecting department for the heavy machines, where such work as that shown in Fig 9 is carried out. On the left-hand side is the erecting shop for motors, which is illustrated in Fig 10. The parts and finished motors seen at the right hand of this illustration show that work is going through in large quantities. A considerable number of the motors in question are for his Majesty's dockyard at Chatham. Fig. 11 is a view taken farther down the main shop, at a point where the armature winding is carried out. This department is partly under the north gallery, and immediately adjoining the hot-room for drying out the wound armatures and coils. It will be seen that the varnishing-room opens out of this hot-room, spirals, after being wound, have a slight cut taken off the outer circumference, and the appearance then of the magnet with this edgewise copper round them is as pleasing as the construction and insulation is sound. An interesting case of strip winding of field coils was going through the shop at the time of our inspection. This was on the field-magnet system of a large turbo-generator, part of an order of six machines, each of 1,000 kw. output. The small diameter and great length of this four-pole magnet, and also its construction in cast steel, prevented the adoption of edgewise winding. Instead of this, the firm adopted a broad copper strip equal in width to the winding space, and wound in a spiral over each magnet. The result, when the bronze packing pieces had been added, was a most mechanical one, and well able to withstand the enormous centrifugal strains found in turbo-generator working. Fig. 14 is a view of the stator of this machine, which is designed for high voltage, and is wire-wound through micanite tubes.

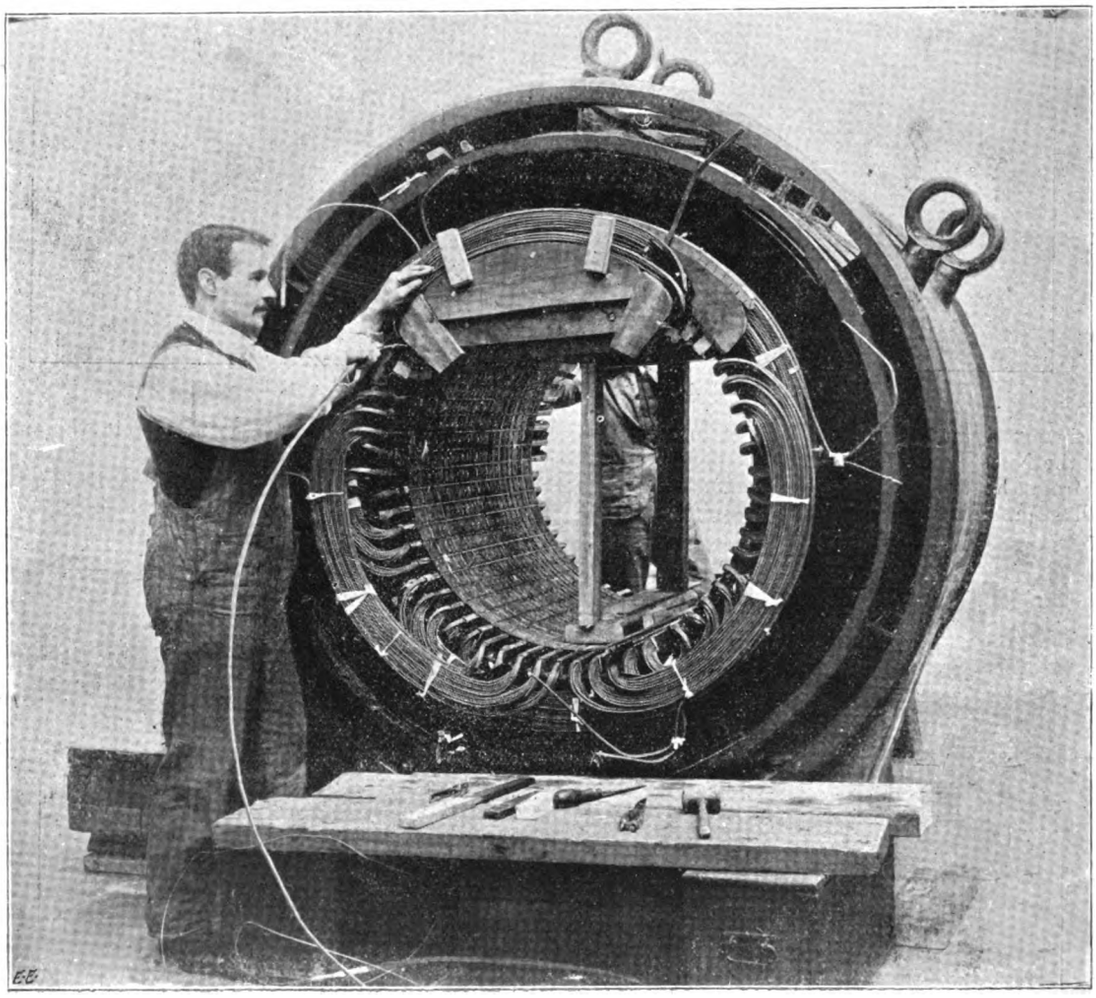

FIG. 14.—Winding the 1,000-KW. Three-Phase Turbo-Generator, built for the Poplar Corporation.

and this avoids any delay in the application of the varnish on to the dried and heated windings. The field-coil winding department is in this north gallery, in the space labelled "Magnet" in the first-floor plan in Fig. 5. In this gallery the insulated bobbins are wound, but not those field coils which are wound with copper strip on edge. This work is done in the south gallery (Fig. 13), and we were particularly struck with the excellent results obtained with the special tools designed by the firm for this purpose. It is well known that if a rectangular copper strip is wound on edge over a circular core, the strains in winding leave the copper thicker on the inner edge than on the outer. In order to avoid this and the consequent looseness at the other edges of the coil, Messrs. Bruce Peebles and Co. use a strip which is not rectangular in section in the first instance. The thicknesses are so proportioned that after winding the thickness is uniform, and the insulation is thus gripped equally at the inner and outer edges of the coil. These

The whole of the micanite used in the works is built up in the department marked "Girls' Room" in Fig. 5, where a number of ingenious moulding devices are in regular use. In this department is also carried on the insulation of the former-wound coils for direct-current armatures. A view of this department is given in Fig. 15, and Figs. 16 and 17 show stators of induction motors before and after winding.

Of the testing shop and test-room we have no illustration to give, as in this hard-driven department the machines are made to show rather what good work they will do than how well they look. The lay-out of the testing shop is good, and the system of dividing up the testing work on to five switchboards enables a large number of machines to be tested simultaneously. By means of throw-over switches, either alternating or direct current machinery can be supplied from each of these boards. Underground mains are provided from these testing boards to groups of terminals at the floor level. In this way the chief of the

Digitized by Google

testing department is able to keep down to a minimum the loose wires, which, lying on the floor of the test-room, become a nuisance to the testing staff, and involve frequently a great waste of time in tracing connections.

stamping and core building department, in which some of the latest tools for punching iron discs are to be seen, nor have we described at all the tool-room with its excellent system of checking the delivery of tools to the workmen

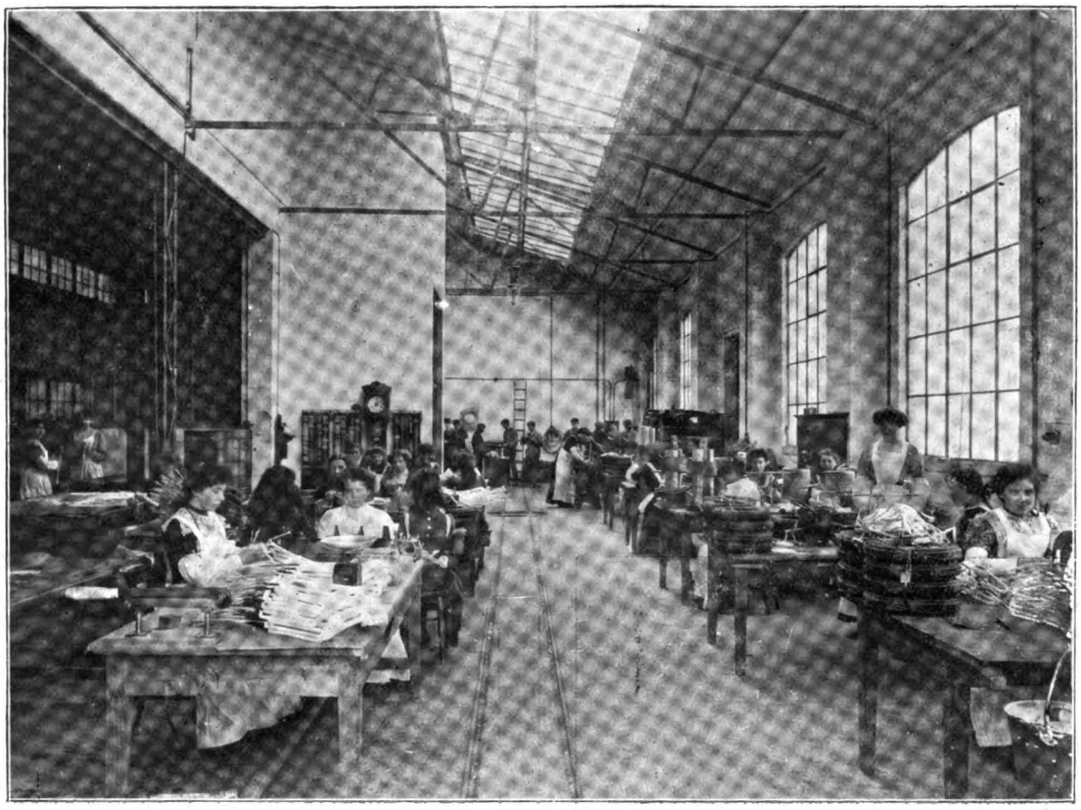

FIG. 15.—The Coil-Insulating and Micanite Manufacturing Department.

After the machinery has passed the critical examination of the testing staff, it passes down the shop through the painting and varnishing rooms. Outside the latter is the packing department, from which goods are dispatched other than those passed into the finished stores. With the large number of orders in hand and demand for prompt delivery. it seemed to us that the packing department was at present

and their return. We can only record our general impression that the firm has been as careful in the design and equipment of these works as they were in the design and construction of their first electrical apparatus, which

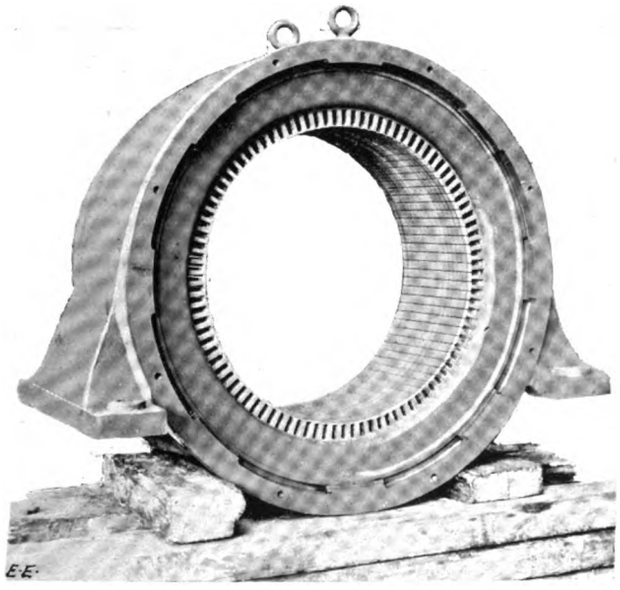

FIG. 16.—Stator Core of Induction Motor.

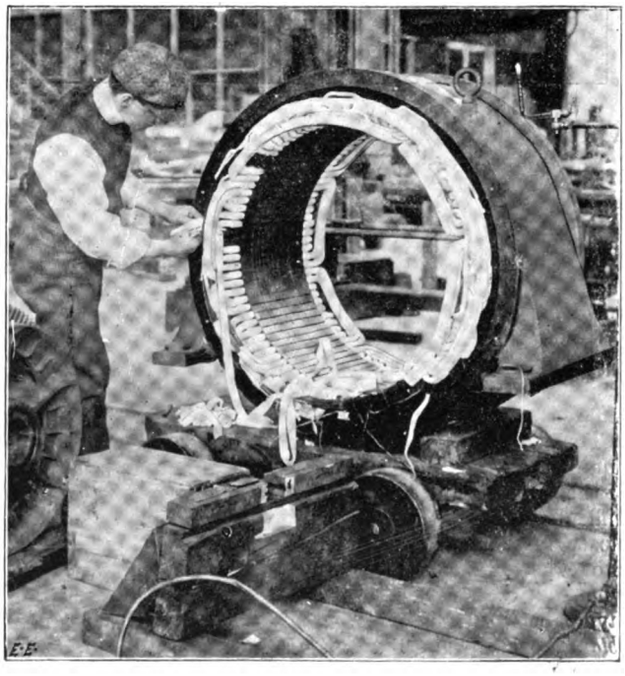

FIG. 17.—Winding a Stator for an Induction Motor.

receiving the great bulk of the goods, leaving the finished motor stores little chance of being filled. This shows that even with the large works, which are now employed night and day, the commercial department of Messrs. Bruce Peebles and Co. are keeping ahead of their manufacturing departments.

Our description of such large works is bound to be incomplete. For instance, we have not mentioned the

gained for them the reputation they enjoy as electrical manufacturers. With the improvements in manufacturing facilities, we see every reason to expect that the machines manufactured at East Pilton will surpass even those turned out from the Tay Works, and that they will more than hold their own in the markets of the world.

HYDRODYNAMICAL AND ELECTROMAGNETIC INVESTIGATIONS REGARDING THE MAGNETIC-FLUX DISTRIBUTION IN TOOTHED-CORE ARMATURES.*

BY PROF. H. S. HELE-SHAW, F.R.S., LL.D., ALFRED HAY, D.SC., AND P. H. POWELL, M.SC., M.ENG.

INTRODUCTION.

Some four years ago, two of the authors of the present paper described a hydrodynamical method of attacking two-dimensional magnetic problems. A full account of this method, including a detailed description of the apparatus used and examples of the results obtained, will be found in a Royal Society paper for 1900 † Here it will be convenient, for the sake of those members who do not happen to have seen an account of the method, to give a brief outline of it. The laws which govern the distribution of magnetic flux in space of two dimensions are identical with those which apply to the stream-line motion of a perfect incompressible fluid in two-dimensional space. If, therefore, we had such a fluid at our disposal, and by causing it to flow between parallel bounding walls determined the distribution of the stream-lines, this distribution would also represent that of the magnetic lines or tubes in a corresponding two-dimensional magnetic problem. This

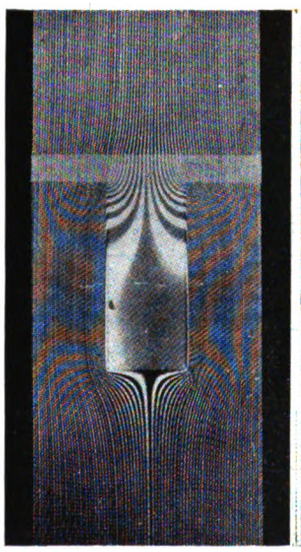

FIG. 1.

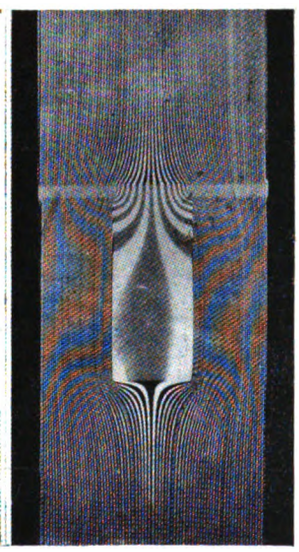

FIG. 2.

is the underlying principle of the hydrodynamical method as applied to magnetic problems.

In trying to put the principle of this method into practice, we encounter the following difficulties: (1) the difficulty of mapping out the invisible stream-lines of the fluid; (2) the fact that there is no such thing as a "perfect" fluid at our disposal, every actual fluid being more or less viscous; (3) the difficulty of finding an analogue for magnetic permeability, in order to enable us to study the flux distribution in cases where the field consists of regions having different permeabilities.

The first difficulty is surmounted by using a colourless liquid into which are injected thin colour bands, consisting of the same liquid mixed with a suitable dye. The second difficulty at first sight appears insurmountable. But a closer mathematical investigation by the late Sir G. G. Stokes‡ has revealed the somewhat astonishing fact that when any viscous liquid is made to flow in a very thin layer between parallel bounding walls, *the stream lines obtained are identical with those of a perfect liquid.* This theoretical deduction was subsequently fully confirmed by us in the paper already referred to. The liquid used by us was glycerine, and the dye for mapping out the stream-lines was a mixture of aniline dye with permanganate of potash. The colour-bands were injected through a series of very minute apertures at one end of the slide between whose parallel plate-glass walls the liquid was allow to flow. The third difficulty consists in devising a method by means of which the effects of varying magnetic permeability may be imitated Now it may be shown, both theoretically and experimentally, that when a viscous liquid flows in a thin parallel layer, the quantity of liquid passing per second across a plane of unit length drawn normally to the stream-line is, for a given pressure gradient, inversely proportional to the cube of the thickness of the liquid layer. Hence, if the liquid is made to flow through several regions of different thickness, the ratio of the cubes of the thicknesses gives the ratio of the permeabilities in the corresponding magnetic problem.

The practical method employed by us consisted in coating one of the thick glass plates forming the slide with a thin layer of paraffin wax, and then forming a cavity or cavities of the required shape by carefully scraping away the wax over certain areas. These areas, over which the liquid layer had a greater thickness, represented the regions of high permeability. The permeability varying in proportion to the *cube* of the thickness of the liquid layer, no difficulty was experienced in constructing slides in which the permeability over certain regions had as high a value as 1,000. The slide through which the liquid flowed being suitably illuminated, a photograph of it was taken, and thus a permanent record obtained of the particular stream-line

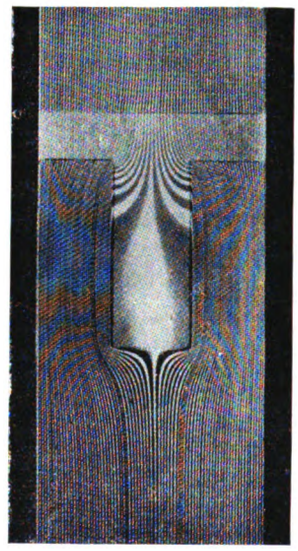

FIG. 3.

FIG. 4.

distribution. The stream-line diagrams which accompany the present paper are reproductions of the photographs so obtained.

The validity of the hydrodynamical method having been established, we proceeded to apply it to some problems in dynamo design whose solution has always been a matter of considerable difficulty. In order to render the investigation more complete, however, we decided to supplement the results obtained by the hydrodynamical method by experiments carried out on an actual dynamo fitted with several armature cores having different sizes of teeth and slots, and different air-gaps. In the calculation of the magnetomotive force required to produce a given magnetic flux in a dynamo having a toothed-core armature, the designer encounters two important difficulties. The first of these is the determination of the reluctance of the air-gap, including the allowance to be made for the distortion due to the armature teeth and for the fringing effect around the edges of the pole-pieces; and the second is the determination of the reluctance of the teeth themselves It is in connection with the first problem—that of air-gap reluctance—that the hydrodynamical method is of particular value. Although attempts were made to apply it to the second problem—that of tooth reluctance—by *continuously* varying the thickness of the liquid layer representing the tooth, yet the difficulties of doing this satisfactorily proved so great that the attempt had to be abandoned, and we preferred to carry out this part of the investigation electromagnetically, using the ballistic method.

Hydrodynamical Investigation of Air Gap Reluctance.

For the sake of completeness, and with a view to rendering the present paper as useful as possible to the dynamo designer, we propose in what follows not to restrict our attention to our own investigations, but to supplement these by an account of the more important researches carried out in this direction by other workers, and to state the results obtained in a form which will render them available for immediate practical use.

A. *Fringing Problem.*—If we except various more or less arbitrary and imperfect empirical rules, the first attempt to deal with this problem in a scientific manner is due to Messrs. C. C. Hawkins and R. Wightman, who, in a paper entitled "The Air-Gap Induction in Continuous-Current Dynamos,"* obtained a correction for the fringing effect on the basis of certain very simple, though incorrect, assumptions regarding the form of the magnetic lines in the vicinity of the polar edges. Shortly afterwards, Mr. F. W. Carter† succeeded in obtaining an exact mathematical solution of an ideal case, which, however, so closely corresponds to the actual problem that from a practical point of view the solution may be regarded as furnishing a perfect correction. The most convenient way of taking the fringing effect into account is to add to the length of the polar

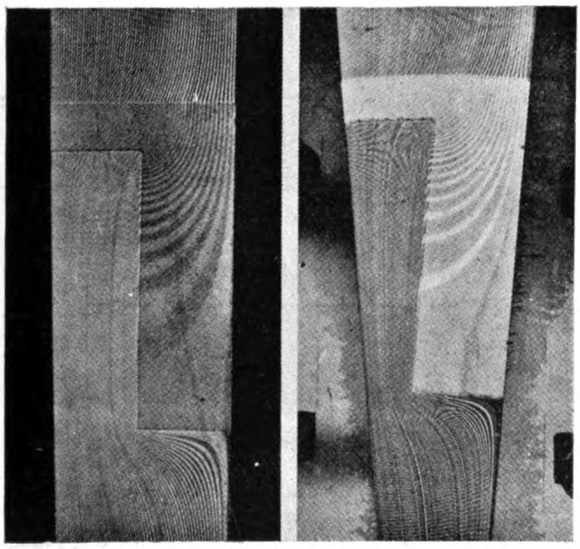

Fig. 5.

Fig. 6.

arc (in estimating the effective cross-sectional area of the gap), a term consisting of the product of the single air-gap length into a certain coefficient, c, whose value depends on the ratio $r = \frac{\text{distance between pole-pieces}}{\text{length of single air-gap}}$, the "distance between the pole-pieces" being measure along the armature circumference, and hence representing the length of the interpolar arc. The following table contains the values of c corresponding to various values of r:

$r=$ 4	5	6	7	8	9	10	12	14	16	18
$c=$1·32	1·59	1·79	1·89	2·15	2·30	2·43	2·65	2·84	3·00	3·15
$r=$ 20	22	24	26	28	30	35	40	45	50	60
$c=$3·28	3·40	3·51	3·61	3·70	3·78	3·98	4·14	4·28	4·40	4·66

By means of this table the necessary correction in any given case may be at once applied.

B. *Problem of the Flux Distortion brought about by Armature Teeth.*—It is at once obvious, without the necessity of going into any elaborate investigation, that the presence of teeth in the armature core is equivalent to an increase in the gap length (or a reduction in the gap area); for the teeth disturb the uniformity of the flux distribution, causing a crowding of the lines into the regions of the polar surface which are opposite the teeth, and thereby increasing the fall of magnetic potential, from the polar surface to the crown of any tooth, above the value which it would have if the distribution were uniform—*i.e.*, if the core were smooth—and the total flux unaltered. Assuming that the exact effect produced by the teeth is known, a convenient method of applying the necessary correction consists in multiplying the gap length by a certain "correction coefficient," and then, using this corrected value, in proceeding with the calculation as if the armature core were smooth—*i.e.*, as if the flux distribution were uniform. The "correction coefficient" clearly represents the ratio of the maximum to the mean induction. It is not difficult to see that the value of the correction coefficient depends on the two ratios s/t and s/g, where s = width of slot, t = width of tooth (at top), and g = length of gap. In Figs. 1-9 are given a series of stream-line diagrams for various values of the two ratios s/t and s/g, and a careful examination of these enables one to form a very good idea of the effect produced by the teeth. The chief value of the diagrams, however, lies in the fact that they enable us to determine the numerical values of the correction coefficient in the various cases. All that is necessary for this purpose is to determine the number of stream-lines per unit of length in the space well under cover of a tooth, and to divide this by the mean number of stream-lines per unit of length for tooth and slot. The values of the correction coefficient so obtained are given in Table I.

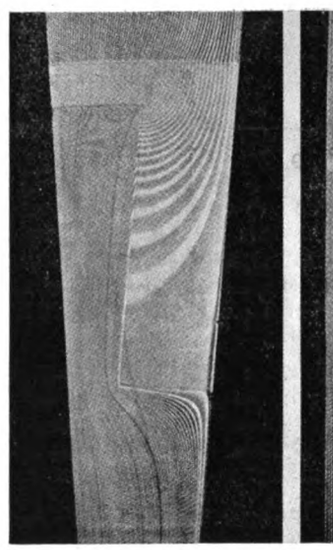

Fig. 7.

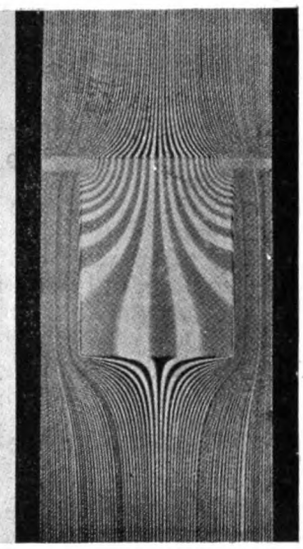

Fig. 8.

Attention may be drawn to one or two features clearly exhibited by the diagrams. Two well-known effects are shown very plainly: the *refraction* of the lines as they pass from a medium of low into one of high permeability, and the crowding of the lines along the sharp edge of the tooth. It will be further noticed that between the straight lines in the region immediately above the tooth and the curved lines entering the slot and passing into the flank of the tooth, and exhibiting a concavity towards the tooth, there are certain intermediate or transition lines which are characterised by a point of inflection, the upper part of the line being concave and its lower part convex towards the tooth; the convexity gradually decreases as we take lines further and further away from the tooth, and is ultimately replaced by a concavity along the entire length of the line. While our experiments were in progress, a very important contribution to this subject appeared by Mr. F. W. Carter,* who followed up his previous success in attacking the fringing problem by working out a solution for the air-gap flux distribution in the case of a toothed-core armature, on the assumptions of negligible pole-face curvature and infinite permeability in the teeth. According to Mr. Carter, the correction coefficient is given by

$$\frac{1+\frac{s}{t}}{1+(1-\sigma)\frac{s}{t}},$$

* *Journal* of the Institution of Electrical Engineers, vol. xxix. p. 436.

† *Ibid.*, p. 925; also *Electrical World and Engineer* of New York, vol. 37, p. 884.

Digitized by Google

where $\sigma = \frac{2}{\pi}\left\{\tan^{-1}\frac{s}{2g} - \frac{g}{s}\log\left(1+\frac{1}{4}\frac{s^2}{g^2}\right)\right\}$.

Mr. Carter's solution furnishes a correction coefficient which may be regarded as quite accurate enough for all practical purposes, and a reference to Table I. shows very satisfactory agreement between the values determined by our stream-line method and those calculated by means of Mr. Carter's formula. Such divergencies as exist in some cases are to be attributed to want of accuracy in working

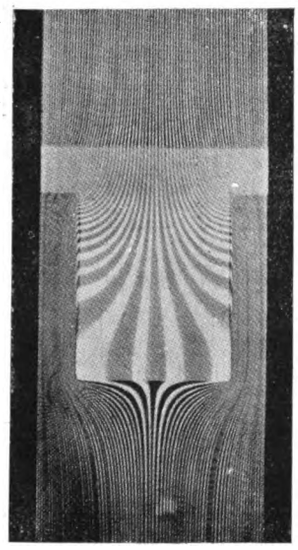

FIG. 9.

out the values from the stream-line diagrams, due to their comparatively small scale. Previous to the appearance of Mr. Carter's paper various attempts were made to deal with the problem, and it is interesting to compare the results furnished by some of these older methods with the correct values now at our disposal.

Method I.—A first very rough approximation may be obtained by assuming that none of the lines pass down towards the slot, but that they all crowd into the tops of the teeth, forming a series of isolated patches, as shown in Fig. 10. The correction coefficient is on this assumption given by $\frac{t+s}{t} = 1 + \frac{s}{t}$, and leads to a very considerable over-correction, which increases with increase of $\frac{s}{t}$.

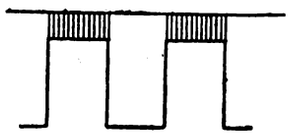

FIG. 10.

Method II.—It is assumed that the effective area of the air-gap is the arithmetic mean of the polar area and that corresponding to the tops of the teeth. The correction coefficient is given by

$$\frac{t+s}{t+\frac{1}{2}s} = \frac{1+\frac{s}{t}}{1+\frac{1}{2}\frac{s}{t}}$$

This method leads to an over-correction when $\frac{s}{g}$ is small, and to an under-correction when $\frac{s}{g}$ is large.

Method III.—The lines are assumed to be straight, and to be distributed in wedge-shaped masses, as shown in Fig. 11. The reluctance over a width of one tooth and slot of a thin layer of unit breadth (measured in a direction parallel to the shaft), and at a distance x from the top of the tooth is $\frac{dx}{t+\frac{s}{g}x}$, where dx is the thickness of the layer. The total reluctance is thus

$$\int_0^g \frac{dx}{t+\frac{s}{g}x} = \frac{g}{s}\log\left(1+\frac{s}{t}\right).$$

But the reluctance corresponding to a smooth core is $\frac{g}{t+s}$.

Hence the correction coefficient is $\left(1+\frac{t}{s}\right)\log\left(1+\frac{s}{t}\right)$

This method leads to an over-correction in most cases. The three methods so far considered take no account of the ratio $\frac{s}{g}$.

Method IV.—This method, due to Messrs. Hawkins and Wightman,* assumes that the lines which fall outside the space immediately above a tooth consists partly of straight lines and partly of quadrants of circles whose common centre is at the edge of the tooth, as shown in Fig. 12. The reluctance of the air-space above the tooth is, per unit length of tooth measured in a direction parallel to the shaft, equal to $\frac{g}{t}$, while the reluctance of an equal length of air-space above a slot is

$$\frac{1}{2\int_0^{s/2}\frac{dx}{g+\frac{1}{2}\pi x}} = \frac{\pi}{4\log\frac{g+\frac{\pi}{4}s}{g}}$$

Hence the joint reluctance of the two air-spaces is, per unit length along shaft, given by

$$\frac{\pi g}{4t\log\frac{g+\frac{\pi}{4}s}{g}} \Big/ \left(\frac{g}{t} + \frac{\pi}{4\log\frac{g+\frac{\pi}{4}s}{g}}\right) = \frac{\pi g}{\pi t + 4g\log\frac{g+\frac{\pi}{4}s}{g}}$$

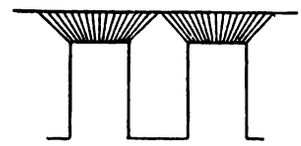

FIG. 11.

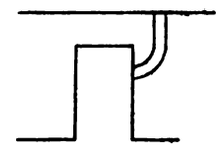

FIG. 12.

Now, since the value of this reluctance for a smooth core is $\frac{g}{t+s}$, it follows that the correction coefficient is given by

$$\frac{1+\frac{s}{t}}{1+\frac{4}{\pi}\cdot\frac{g}{t}\log\left(1+\frac{\pi}{4}\frac{s}{g}\right)}.$$

For the sake of comparison, the values calculated in accordance with each of these methods are included in Table I., and an examination of the results shows that none of these older methods is reliable.

RELUCTANCE OF TEETH IN A SLOTTED ARMATURE.

The problem of determining the reluctance of the teeth has generally been dealt with on the assumption that the equipotential surfaces in the teeth and slots are cylindrical surfaces coaxial with the core discs. This assumption is far from being correct, as is at once evident by an inspection of the stream-line diagrams and an examination of the experimental results given below. Nevertheless, for practical purposes the assumption yields sufficiently accurate results. The problem is considerably more complicated in the case of armatures of small diameter, where the taper of the teeth may produce a very considerable difference between the cross-sectional areas of the top and bottom of a tooth. The most satisfactory method of dealing with the problem in such cases is that given by Mr. W. B. Hird in a paper contributed to the *Journal* of this Institution.†

The object of the experiments about to be described was to investigate the exact distribution of the magnetic flux in the teeth and slots of a slotted core under varying conditions of excitation, and with varying length of gap and width of tooth.

DESCRIPTION OF APPARATUS.

The apparatus used was specially designed for the purpose, and was constructed in the workshops of the University of Liverpool. The dynamo (Fig. 13) was of the single-bobbin type, with field core and pole-pieces of Allen's dynamo steel. The pole-pieces were bored out to a diameter of 5½in., and into the space between them could be introduced any one out of a set of five experimental armature cores. The cores consisted of sheet-iron stampings, supplied by Messrs. Sankey and Co., threaded on the shaft, and maintained in position by means of a feather key. The details of the five cores are given in Fig. 14, which also shows the positions of the search coils, by means of which the flux at three different cross-sections of a tooth was determined. The three cross-sections corresponded to the

Digitized by Google

top, the middle, and the bottom of a tooth. In addition to the three coils surrounding the tooth, a fourth coil, of width equal to that of a tooth and slot, was used for the purpose of determining the total flux per tooth and slot, and the mean value of the gap induction. This coil was slung in position by means of silk threads suitably supported from the armature shaft, and provided with a device for adjusting the coil in the exact position required (the middle of the air-gap). Each of the three coils surrounding the tooth consisted of five turns of No. 46 wire. Considerable difficulty was experienced in insulating the coils satisfactorily, but this was successfully overcome.

In order to avoid the various difficulties and uncertainties connected with the measurement of the magnetic flux by the methods of breaking and reversing the exciting current, we decided to produce the reversal of flux by a bodily rotation of the armature with its search coils through 180deg. For this purpose the armature was first placed in such a position as to bring the tooth carrying the search coils opposite the middle of one of the pole-pieces. The particular search coil in use being in connection with the ballistic galvanometer, the armature was then suddenly rotated through half a revolution, the tooth being thereby brought opposite the middle of the other pole-piece. This operation occupied an interval of time not exceeding one second. In order to limit the motion of the armature, the shaft was fitted with a striker, T (Fig. 13), capable of moving between two steel stop-pins, F F. In order to prevent excessive shock due to the sudden stoppage of the

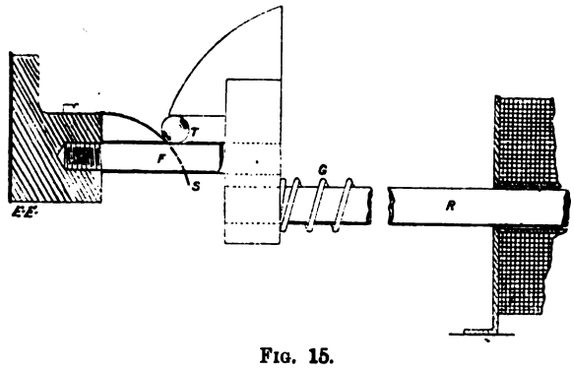

FIG. 15.

armature, buffer springs, S (Fig. 15) were provided, and in order to prevent subsequent recoil suitable catches, one of which is clearly shown in Fig. 15, were fitted. Each catch is forced outwards by a spring, G, which is normally in compression, and which surrounds the core, R, of a solenoid, the catch being attached to the end of the core. When the solenoid is excited, it sucks in its core, withdrawing the catch and leaving the armature free to rotate through 180deg. A similar coil-and-plunger release was fitted to the catch on the other side.

In order to arrive at a correct estimate of the net cross-section of iron in the tooth, a large number of measurements was made of the thickness of the discs forming the different cores, and the number of discs in each core was carefully counted. The exact dimensions of the various exploring coils were also determined with great care. The results of the more important of these measurements are given in Table II.

TABLE II.—Details of Armature Cores and Search Coils in Gap.

The moving-coil ballistic galvanometer used in these experiments was of special construction; we found that no suitable commercial instrument could be obtained. A detailed account of the principles underlying the design of such an instrument has already been published by one of us.* It may, however, be mentioned that the periodic time of the instrument was about 80 seconds, and that the electromagnetic damping device consisted of a copper disc suspended below the coil and acted on by a small electromagnet. Throughout the experiments the galvanometer was very frequently calibrated by means of a standard solenoid.

(To be continued.)

* B.A. Report for 1903; or *Electrician*, vol. li., p. 1,013.

ELECTRIC RAILWAY TESTS.

The Electric Railway Test Commission have concluded a series of tests at the St. Louis Exhibition on a single-truck car of the St. Louis Car Company. The car measures 33ft. over all. Its weight with equipment is 15 tons, besides which 3,100lb. of steel billets were carried to represent an average load of passengers. The testing equipment included a General Electric Company recording ammeter for the line current, an ammeter in each motor field, a line voltmeter, and voltmeters across each motor. A Boyer speed recorder was used for speed readings. The car was also equipped with an electrical speed time and speed distance recording device, consisting of a chronograph drum revolved at constant speed and furnished with two pencils, one of which records the time at intervals of five seconds, and the other denotes the distance by means of a track circuit breaker. This breaker consists of a sliding contact, held in place by springs and mounted on the car truck. As the car moves, the circuit is broken by the arm on which the contact is mounted, striking wire "trippers" located at various distances apart. The speed is indicated on a voltmeter connected to an ignition dynamo, which is driven from the axle. In order to preserve an absolutely uniform field strength, this dynamo is excited by storage-battery current maintained at a constant value. The observer follows the needle with a pointer rotating about an axis on the instrument case and fastened to the second pencil on the drum. This pencil is moved against the tension of a spring. Satisfactory results have attended the use of this device. The tests included motor heating runs with several different schedules, with hand braking, and repetitions with magnetic braking. The car was fitted with two Westinghouse No. 56 motors, magnetic brakes of the Westinghouse Company, and the B 23 controllers of the same company. The schedules were run throughout the day until a constant temperature was reached, and two sets of complete readings were taken during the run, each of about an hour's duration. The distance run was 825ft., giving 6 6 stops per mile. The average time from start to start of each run was 52 seconds, corresponding to a schedule speed of about 11 miles an hour. During these runs the indicating instruments were read every five seconds The Boyer speed recorder was run back and forwards between the two points marking the ends of the run, and thus gave the average curve direct. High-speed tests are to be carried out on a typical interurban car and a special car to measure the air resistance.

Wireless Telegraphy.—The German Society of Naval Architects, which was founded five or six years ago on the model of the British Institution of Naval Architects for the discussion of technical and scientific questions connected with the navy, held the first meeting of its annual session at the Charlottenburg Technical High School last week. Prof. Braun, of Strassburg, read a paper on the methods and aims of wireless telegraphy. One of the speakers, in commenting upon the subject, expressed a desire to see the various systems of wireless telegraphy united or amalgamated as a matter of international convenience. It is announced that installations of De Forest wireless telegraph instruments are to be made by the United States Navy at Panama, Guantanamo, Key West, Pensacola, and Porto Rico for ranges varying from 450 to 1,000 miles, and within the near future stations will also be established in Hawaii, Guam, and the Philippines. One contract calls for 300 stations in the Philippine Islands.

NOTES.

Wireless Telegraphy.—We understand that the "Telefunken" system is now being tried on the lightship "Nantucket."

The De Forest System.—It is reported that the De Forest Wireless Telegraph Company of America are competing with the land wires in sending messages between St. Louis and Chicago at the ordinary Western Union rates.

Royal Society.—The anniversarial dinner was held at the Hôtel Métropole on Wednesday, the president, Sir Wm. Huggins, in the chair. A large and distinguished gathering assembled, and a number of interesting speeches were made, of which particulars will appear in our next issue.

Electro-Harmonic Society.—For the next concert, which takes place on the 9th inst., with Mr. F. H. Nalder in the chair, another entertaining programme has been arranged. The vocal talent comprises Messrs. Harold Wilde and Robt. Radford, and the instrumental performers will be Messrs. E. F. James, B. W. O'Donnell, and A. E. Izard, while miscellaneous items will be contributed by Messrs. H. Scarsdale, C. Wreford, and N. Jackson. The musical directors will, as usual, be Prof. Izard, R.A.M., and Mr. T. E. Gatehouse.

Junior Institution of Engineers.—A large number of the members, accompanied by the president (Mr. W. H. Lindley) and the chairman (Mr. Samuel Cutler, jun.), availed themselves the other day of the opportunity of visiting the central station of the South Staffordshire Mond Gas Company at Dudley Port, and the most recent additions to the Birmingham Corporation gasworks at Nechells. The party spent an enjoyable and useful time in a thorough inspection of these extensive works, aided by the descriptions and explanations of the officials.

Electric Wiring Loans.—We notice that the London County Council have recently authorised a further loan to the Woolwich Borough Council for the purpose of assisting the wiring of consumers' premises for electric lighting, and for the supply of motors and other electrical appliances on hire. The interesting point in this case is that the period fixed by the County Council for the repayment of the loan is eight years, which seems to us to be a liberal one considering the risks of the business which the Woolwich Council are undertaking. It will be remembered that powers for wiring consumers' premises and hiring out motors, etc., were granted by the Woolwich Borough Council Act of 1903.

Marconi Long-Distance Transmission. — A message by wireless telegraphy has been transmitted from the Marconi Company's station at Poldhu to a station belonging to the Italian Government at Ancona. It was addressed to Admiral Mirabello, Italian Minister of Marine, who has taken a great interest in wireless telegraphy. The station at Ancona is a small one, and was not originally intended for long-distance work. The mileage between Poldhu and Ancona is about 1,000, and almost entirely over land, and in order to reach their destination the waves had to pass over nearly the whole of France and a considerable portion of Italy, including the highest mountains of the Alps.

Personal.—We regret to note that owing to indifferent health Mr. Musgrave Heaphy has retired from the position of electrical engineer and scientific adviser to the Phœnix Assurance Company. The services rendered by Mr. Heaphy to the electrical industry in its earlier days by fixing a high standard for electrical wiring work are well known and highly appreciated throughout the country. This appreciation is shared by the directors of the Phœnix Assurance Company, who have retained his services as their consulting electrical engineer. We understand that the retaining fee is a most liberal and substantial one. Mr. Heaphy is to be succeeded by Mr. L. G. C. Russell, A.M.I.E.E., who for some time past has acted as electrical engineer to the company. We trust that Mr. Heaphy will long be spared to enjoy relaxation from the arduous duties which he has so ably performed for many years past.

Leeds Section.—This local section last week paid visits to the works of Messrs. W. T. Glover and Co., Limited, at Trafford Park, Manchester, and to the power station at Formby for operating the Liverpool-Southport line of the Lancashire and Yorkshire Railway, the party being indebted for permission to Mr. E. A. Claremont, managing director of Messrs. Glover and Co., and Mr. J. A. F. Aspinall, general manager of the railway company. The party were piloted around the extensive Trafford Works by members of Messrs. Glover's staff, who described the process of manufacture in detail. Subsequently the company proceeded to Formby, where they were shown over the generating station by Mr. O'Brien, the resident engineer, and others of the staff, who explained everything in the most lucid and able manner. Altogether, a most enjoyable and instructive day was spent. Both Messrs. Glover and the Lancashire and Yorkshire Railway Company made careful arrangements for the conveyance of the visitors.

Personal.—Lord Kelvin, who was elected to the chancellorship of the University of Glasgow in April last, was installed in that office on Tuesday, in the presence of a distinguished gathering. Apart from his lordship's great record in the world of science, it is particularly fitting that this honour—usually reserved for the politician—should have been conferred upon him, as he has been identified with the university in various capacities practically all his life, while his father, also one of its students occupied the chair of mathematics. In opening the ceremony the vice-convener associated his lordship with Bacon and Newton as the leading exponents of Christian philosophy. No sooner had the ceremony been completed than it devolved upon Lord Kelvin to confer the honorary degree of LL.D. upon a Royal lady—Princess Louise (Duchess of Argyll)—who has taken a prominent part in the promotion of the higher education for women. Subsequently his lordship delivered a short address of a reminiscent character, and expressive of his gratification at attaining the highest honour his *alma mater* could bestow. We trust that his lordship may be spared to enjoy for many years this recognition of his services to the university and to science.

The Enlargement of Victoria Station.—The Civil and Mechanical Engineers' Society visited last Friday the works connected with the enlargement of the Victoria Station of the London, Brighton, and South Coast Railway Company. It will probably take another two years to complete the work, but the progress already made enabled the party to obtain a good idea of the general scope of the undertaking. The immediate reason for the enlargement is the need of greater facilities for dealing with traffic at the station. Hitherto there has been but one "up" and one "down" line at the terminus, rendering it difficult, if not impossible, to develop the traffic. The company hope that with the service of fast trains which the enlargement will enable them to run, more business people will be induced to live 20 or 30 miles from town in the picturesque rural districts of Surrey. The new station will have a width of 320ft. and a length of 1,500ft., as compared with

Digitized by Google

a width of 230ft. and a length of 800ft. in the case of the present station, while the number of running tracks at the entrance to the station will be increased to something like a dozen. Great improvements will also be carried out in the external features of the station. When the work, which involves a total outlay of something like a couple of millions, has been completed, the old station will scarcely be recognisable. This indicates an admirable spirit of enterprise, but what of the electrification project?

Water-Tube Boilers.—At last week's meeting of the North-East Coast Institution of Engineers and Shipbuilders, Mr. W. R. Cummins read a paper on "A Comparison of Vertical and Horizontal Tubes in Water-Tube Boilers." The author discussed the relative merits of the two types of tubes, with special reference to the conditions which have to be fulfilled to make a commercially successful boiler. The necessary conditions for success he divided under four heads—those affecting the fuel economy, those affecting the weight and space economy, the conditions affecting the cost or capital economy, and the conditions affecting the working or maintenance economy. The balance of advantages appeared to Mr. Cummins to be with the vertical tube boiler. This was to a great extent confirmed by the last report of the Boiler Committee, who gave much praise to the Yarrow boiler. The choice of a boiler, however, must depend entirely on the conditions required in each particular case. On a torpedo-boat everything must be sacrificed to weight and space economy. On a battleship or cruiser weight and space were still important, but sacrifices must be made to fuel economy and working economy. On a liner fuel economy and working economy were paramount. On a tramp steamer cost economy was most important. In all cases, however, fuel economy must be a paramount consideration. An interesting discussion ensued on what Lord Armstrong, the president, termed "this very vexed question."

Tramway Accidents.—One consideration which actuated the Sheffield Corporation in framing a by-law (since withdrawn) for limiting compensation for injuries to £25 was the prevention of exorbitant claims, and to this extent, at any rate, their action was justifiable, if the method adopted was not. Where a passenger sustains serious injury, physical or mental, he has a legal and moral right to adequate compensation; but it is no uncommon thing for a traveller who meets with a few abrasions to put in a claim for substantial compensation, often on the plea of shattered nerves. This procedure has not infrequently been attended with success, and ultra-sympathetic juries have been known to award damages quite out of proportion to the extent of the injuries. The spectacle of a melancholy-looking individual with elaborately-bandaged arm is apt to create upon the too-compassionate juryman an impression which medical evidence does not always counteract. A case came on for trial the other day in the Nisi Prius Court (Ireland) in which the plaintiff claimed damages to the tune of £500 for injuries which he alleged he had received through the negligence of the Dublin United Tramways Company. When the case was called on the plaintiff was conspicuous by his absence, and the action was thereupon dismissed. Seeing that the case had advanced to the trial stage, it could scarcely have been pecuniary motives that restrained the plaintiff from pursuing his suit, and the inference, therefore, is that he was dubious about the possibility of establishing his claim. Whatever be the explanation in this instance, it is not surprising that many tramway owners are apt to look askance at claims for heavy damages.

Publications Received.—"The Dynamics of Particles and of Rigid, Elastic, and Fluid Bodies," by A. G. Webster (Leipzig, B. G. Teubner. Marks 14).—"Elektrotechnik in Einzel-Darstellungen," by Dr. G. Benischke (Braunschweig, Friedr. Vieweg und Sohn. Marks 5·50).—We have received the November number of the *Journal* of the Electric Club, Pittsburg, U.S.A., which contains articles on "Electric Railway Braking," by S. J. Fuller; "Polyphase Induction Regulators," by G. H. Garcelon; "A Slip Indicator," by C. R. Dooley; "The Polyphase Induction Motor" (continued), by B. G. Lamme, and other matter.—"The Metric Fallacy and the Metric Failure in the Textile Industry," by F. A. Halsey and S. S. Dale. (New York: D. Van Nostrand Company. 1dol.) This volume, as the title indicates, is uncompromisingly hostile to the metric system. The reader may not agree with all the conclusions it contains, but the authors have evidently been at considerable pains to collect information and statistics on the subject, so that the work furnishes a compilation of no little interest on this vexed question. We reproduce the following passage from the introduction: "With their system of weights and measures as a foundation, the English-speaking peoples have built up the greatest commercial and industrial structure the world has known. This system they are asked to abandon for the benefit of others at a cost that is beyond estimate, and for compensating advantages that to themselves are wholly trivial and imaginary." The publication is primarily designed to present the case for the United States, but in many respects the arguments are of a general character. The *Transactions* of the American Institute of Electrical Engineers for November contain a paper on the "Transposition of Conductors," by Mr. F. F. Fowle, an abstract of which appeared in a recent issue; and the discussion at St. Louis on "Different Methods and Systems of Using Alternating Current in Electric Railway Motors."

Rats!—To enlist this destructive rodent in the construction of telephone systems may sound empirical to the English engineer, but we have it on the excellent authority of our American contemporary *Sound Waves* that the familiar pest has been found a valuable assistant in this work. To stimulate our four-footed coadjutor, however, it is necessary to introduce his traditional enemy the ferret. Then the process is simple. The subterranean tubes for the reception of the cables having been laid, a rat is let loose at the starting point. Having run a little way, a trained ferret, with a string to his leg, is turned in after him. The tubes run into manholes at intervals, and the rat, furtively glancing back, sees the glaring eyes of his arch-foe rapidly approaching. By the end of the section of tube the rat is either overtaken or falls into the manhole, and then another rat is requisitioned to run the next block. At the end of each section the string is removed from the ferret's leg, and a small rope, which is then attached to the other end of the string, is hauled through. In turn a heavy cable, consisting of two or three hundred wires, is attached to the rope and likewise hauled through the tube. Presumably, it is necessary to see that the rat receives a liberal handicap, otherwise his opponent might catch him prematurely and malinger midway in the tube; but our Transatlantic cousins are capable sportsmen, and doubtless adjust these matters satisfactorily. This new ally was of such utility in the laying of the Des Moines-Omaha line that the Sioux City Telephone Company, who are about to construct a system, have advertised for a large consignment of them, "church rats preferred." Apparently, the ecclesiastical species yield a "higher efficiency" than their larger brethren of the stable. As the result of this novel method of laying cables a decadent industry shows signs of revival, the cult of the rat-catcher having received a fresh impetus among the juvenile division of the community.

Commercial Conditions in South America.—Enterprise in some foreign countries, and particularly Spanish-speaking countries, is often beset with peculiar difficulties. Not long ago it was stated at the meeting of a Spanish electric tramway, financed with English capital, that trouble had been experienced with the employés because the conductors resented the company's action in objecting to their appropriating a considerable portion of the fares to their own use. Engineering pioneers have sometimes been assisted by the aptitude of the natives; at other times they have been handicapped by their racial eccentricities In the South American republics, where there is a large amount of British capital invested, proprietors of public undertakings have suffered from the exactions of the authorities as well as the vagaries of the workmen. It is gratifying, therefore, to see the Argentine Government lending substantial support to commerce in the latest difficulty with which it finds itself confronted in that part of the globe. The leading countries of that continent have, statesmen opine, emerged from the long era of perpetual revolution, but, like the most progressive nations, they are still subject to disputes between capital and labour. An extensive strike movement is proceeding, and although certain services have had to be curtailed, the inconvenience to the public has been largely ameliorated through the firm attitude of the Government. The English-owned railways and tramways have been comparatively free from molestation, and the telephone service has been resumed through special police protection being afforded to willing workers, while the Government has loaned some of its engineers and stokers to private enterprise. This conduct is in happy contrast to that of the late administration during the last railway strike, and is calculated to inspire investors with confidence in developing the great natural resources of those regions.

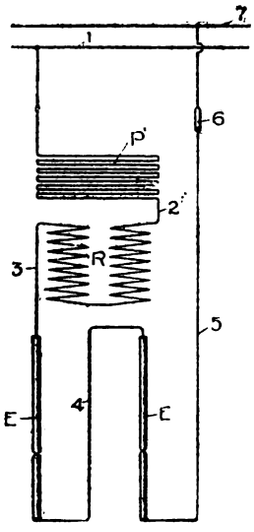
Telephonic Eavesdroppers.—The denizens of the remote parts of Kansas State enjoy the advantages of the telephone, but, rather singularly, they—or, at any rate, the female portion—relish its disadvantages still more. The outlying districts are in telephonic communication with four centres, whence messages can, if desired, be transmitted by telegraph to any part of the continent. It is chiefly for local purposes, however, that the service is utilised. By means of the telephone tradesmen order goods from the towns, ladies make their purchases, and sometimes the physician is consulted. Among the inhabitants of these regions are numerous ranchmen, who no longer pursue, or are pursued by, predatory Indians, as in the days of Mayne Reid, but participate in the use of the telephone and other up-to-date achievements of civilisation. To their wives the telephone is a source of especial gratification. The instruments are all on the same wire, and the sound of the bell is a signal for all to "get in" and listen. They even volunteer to interpret what the speaker is saying if the other communicant cannot understand, regardless of irritable commands to "get off." In this way the news of the locality for 60 miles around is circulated, and over the evening fireside the good wives faithfully detail to their lords the advent of the latest babies, the impending weddings, and other joys and tribulations of their neighbours, to say nothing of the sales of cattle and the prices realised. One of the functions of wireless telegraphy has been to institute transmarine journalism; the effect of telephony in Kansas seems to be to supplant the newspaper. We learn from our Chicago contemporary, the *Telephone Magazine*, that some of the lines are constructed in primitive style, and are ill-fitted to withstand rough climatic and other conditions. It is probable that before long the different lines will be merged into one concern and reconstructed upon more stable principles, but in modernising the system the owners may perhaps feel constrained to retain the single-wire arrangement, lest the service be divested of its great attraction to a large section of the subscribers.

New Schemes.—We gave last week a list of applications for power to embark upon electric traction and lighting schemes, and another crop appears in the current issue. This concludes the roll of projects for which sanction is sought by provisional order, Friday last being the final day for depositing such notices, but there is further time for lodging Bills. Out of the numerous applications, a quantity are, as usual, merely for extension of time or similar purposes, but the list includes some notable schemes. The most ambitious is that presented by a concern styled the Administrative County of London and District Electric Power Company, which seeks power to distribute as well as to supply in bulk an area extending from Hounslow to Gravesend and from Walthamstow to Sutton. Another attempt is being made to pass the East London and Lower Thames Electric Power Bill, which was rejected last year from financial considerations. The Metropolitan Electric Supply Company, the North Metropolitan Electric Supply Company, the Charing Cross and Strand Corporation, the County of London Supply Company, and the City of London Electric Lighting Company, are all seeking power to extend their areas, and in some cases to distribute energy as well as to supply in bulk. In the department of traction, the Central London Railway Company are making another effort to extend their line to Liverpool-street, returning by a loop through the Strand and Hammersmith to the present terminus at Shepherd's Bush. The London County Council are having another try with their over-the-bridges' scheme, and the Croydon Corporation seek power to construct additional tramways within and without the borough, and also to supply electrical energy in bulk outside their boundaries. The Liverpool and Birmingham Corporations are applying for sanction to their big schemes of tramway extension. Promoters are evidently not deterred by the notice issued a few weeks ago in regard to new tubes, and the London Traffic Commission, as besides the Central Railway Company's scheme, the Great Northern, Piccadilly, and Brompton Railway are applying for power to construct an extension from Kingsway to Waterloo, and the Baker-street and Waterloo Railway Company ask permission to construct new and abandon existing subways. The projected line from Hammersmith to the City and thence to Palmer's Green is also being revived by the Hammersmith, City, and North-East London Railway Company. If the bulk of these schemes are proceeded with, the parliamentary committees are likely to be kept pretty busy during the next session.

Double-Carbon Arc Lamps.—A direct-current constant-potential twin arc lamp adapted to modern conditions has been patented in the United States by Mr. C. E. Harthan, of the General Electric Company, and some particulars of the invention, with a diagram showing the general arrangement of the electrodes and wiring, appeard in the *Western Electrician* of Chicago. The construction of the lamp permits the two pairs of carbons to be placed near together, preferably about 2in. apart, so as to prevent the arcs from being too near the inner surface of the globe. It is found that by bringing the carbons near each other the current traversing one pair has a steadying effect on the arc between the other pair, but this effect is lost if they are so near as to exert a blow-out action. The positive line, 1, is connected with the resistance coil, P_1, from which a

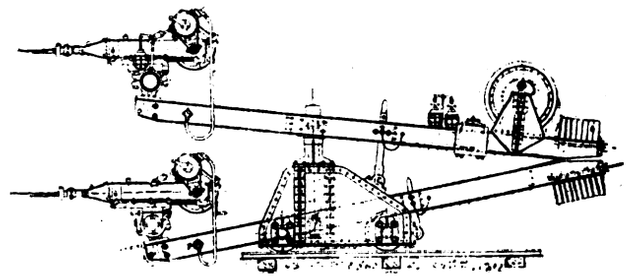
Digitized by Google

lead, 2, runs to one terminal of the magnet, R, whose other terminal is connected by lead 3 with that one of the carbon tubes whose lower carbon is supported by a leg of the lamp. The binding post at the other end of this leg is connected by lead 4 with the other carbon tube, and the circuit therefrom is by way of the other leg of the lamp, a gas-cap lead, 5, and switch, 6, to the negative side of the line 7. In order to permit the use of enclosing globes of different lengths, an improved supporting device is provided, consisting of a wired bail suspended by springs, and having at its lower end a ring to receive the lower end of the globe, and a depending loop serving as a fingerhold in pulling down the bail to release the globe. The ring may be either of sheet metal,



or integral with the bail and loop. Each spring is supported by an eyelet on the underside of the base-plate. The upper end of the enclosing globe fits in an annular groove in the gas-cap, and the hot gases escape through tortuous passages in the cap to the outer air.

An Electrically-Bored Tunnel.—Electricity is figuring extensively in the construction of the Karawanken tunnel in Austria. The tunnel has a minimum height of about 9ft. 10in. and a minimum width of about 8¾ft. Boring operations were commenced from both ends. The material excavated is removed by an electric railway, the tunnel is illuminated electrically, ventilation is provided by electrically-driven compressors, communication is maintained by telephone, and electric boring machines are in use. The *Electrical World* of New York describes the power stations, one being installed at Rothweinbaches, a distance of six miles from the south tunnel portal, and another at Rosenbach, a distance of 1¼ miles from the northern tunnel portal, the line voltage being 5,000. The water power available at Rothweinbach was equivalent to 900 h.p., with a fall of 28·4m. The power house at Rothweinbach was equipped with three turbines of 450 h.p. each, a three-phase alternator of 400 kw. capacity being directly coupled to each turbine, the speed being 750 revolutions per minute. These machines supplied three-phase currents with a frequency of 50 periods per second and a pressure of 550 volts. The entire loss on the transmission line from the station to the tunnel was found to be 10 per cent. For operating the electric locomotives, a sub-station was erected and equipped with step-down transformers and a 250-kw. rotary converter. The sub-station received current from the transmission line at 5,000 volts, and two stationary step-down transformers of 230 kw. each were provided for lowering the pressure to 350 volts, which the rotary raised to 560 volts direct current. The electric boring machines constitute an interesting feature. These are each equipped with four motors of 43 h.p. capacity, together with transformers on each machine, the boring tools each being provided with 2-h.p. motors operating the drills as indicated in the illustration. The electric boring machines consist of a car provided with a cable drum and several electric drills mounted on the adjustable frame. Both direct-current and alternating-current motors have been utilised in the operation of these machines. The 5,000-volt, three-phase current from the high-tension power transmission line is conducted through a three-conductor, iron-armoured, high-tension cable of 3×6mm.^{2} copper cross-section to a transformer of 25 kw. capacity, which is used for transforming the pressure to 250 volts. The low-pressure cables are also iron-armoured and lead-covered, with three conductors each of 35mm.^{2} cross-section. These cables connect with the boring machines, which are provided with drums holding about 200ft. of cable. The results obtained compared very favourably with those given by pneumatic boring machines in another part of the tunnel.



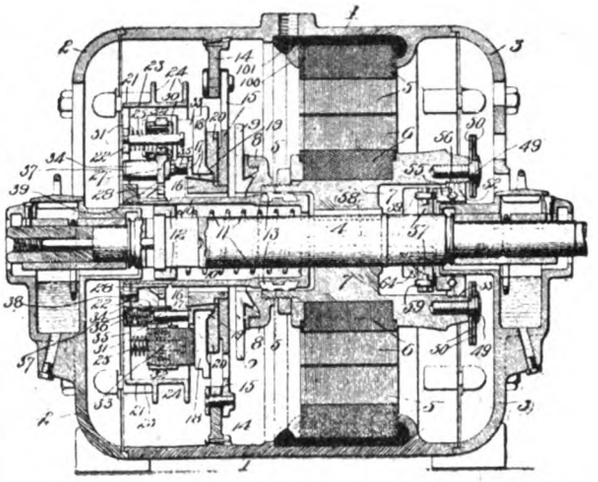
The electric boring machines constructed by the Oesterreichischen Siemens-Schuckert Werke, now in operation at the north side of the tunnel, excavated 3,300ft. during the six months from January to June last.

The St. Louis Exhibition.—One of the greatest, if not the greatest, of the features of the St. Louis Exhibition has been the electrical section. In an historical *résumé* of the whole exhibition *Dun's Review* gives a comprehensive survey of the electrical department. Of the many exhibits shown, some of the most interesting and impressive were a few that showed the amazing progress that has taken place in the practical employment of electricity during the lifetime of men still young. The display included the famous electric locomotive built at Menlo Park, N.J., in 1880, the first Edison direct steam-driven electric generator, the first three-wire installation ever made — that of the electric lighting plant at Sunbury, Pa., in 1883—the first electrolier ever made, and a collection of relics of various kinds connected with the earlier work of Edison, in whose honour the exhibit was arranged. Specimens were shown of practically every type of incandescent lamp made during the quarter-century that has elapsed since this great invention was first given to the world. In many other exhibits, not primarily intended to be historical, the historical element was a noteworthy feature—in fact, the spectator was constantly impressed with the rapidity with which epoch-making inventions in nearly every department of electricity have been evolved, perfected, and adopted for commercial use on a scale that has already caused them to seem commonplace. Since the Chicago Exposition the number of fundamental types of electric lights have been increased from two to five, to the incandescent lamp and arc light being added the Nernst light, the Bremer arc and the Cooper Hewitt mercury or vapour lamp. One of the most interesting exhibits showed a piece of dry goods under four different forms of electric light—the effects varying in a most surprising manner as the lights were changed. Several exhibits, notably in the French section, showed the progress made in the manufacture of electric light fixtures, while others indicated in a most

Digitized by Google

effective manner the part that suitable globes and reflectors play in the attainment of satisfactory lighting effects. The western end of the machinery building contained the most important portion of the exhibits illustrating the latest developments in electrical generators. These exhibits exemplified the steady increase shown in the size of steam-driven electrical units in response to the widespread demand for enormous power-houses, chiefly for electric traction work. By means of models, and some examples of the machines themselves, a fairly clear conception was given of the progress in electrical generation from water-power plants. At Buffalo, in 1901, the keynote of the exposition was electricity thus generated, yet at that time Niagara only furnished 120,000 h.p., while shortly the total in use there will be 550,000—a startling increase in three years. In California, Mexico, and in many parts of the world, electric plant driven by turbine waterwheels are being installed on a mammoth scale, while current is being transmitted successfully to distances that a decade ago would have been deemed impossible. One noteworthy exhibit at St. Louis was a motor for street cars designed to use an alternating current without the intervention of a sub-station. Motors were shown in every size and for every purpose, the smallest, of $\frac{1}{8}$ h.p., supplying just enough power to run a sewing machine. The exhibition of electrical street railway appliances included a controller so adjusted as to turn on the power gradually and automatically, obviating the annoying jerk caused by careless motormen. The Intramural Railway, owned and operated by the Exposition Company, constituted in itself a model exhibit, every feature of the equipment being of the latest type. Many electric locomotives were shown for a wide variety of uses, the more powerful types to replace steam-engines on railways, others for mines, factory yards, etc. A memorable feature of the exhibition has been not only the exhibits, but the use commercially of the De Forest wireless telegraph. Two long-distance wireless telegraph stations were erected on the grounds, one a steel tower 300ft. high, the other a wooden mast 210ft. in height at the opposite end of the exposition enclosure. Messages were sent between the two for the general public, while Press messages were sent from the steel tower to two newspaper offices in the city of St. Louis. About 5,000 words of copy were transmitted daily, consisting of world's fair items collected by regular reporters of the papers and sent at a speed of 30 to 35 words per minute. Messages were also sent successfully all summer to Springfield, 105 miles distant, and eventually to Chicago, 300 miles away. These tests were especially interesting, as heretofore most wireless experiments have been across water spaces. A telegraph transmitter for sending messages y wire on the Morse system was shown that was capable of telegraphing 1,000 words per minute. All the numerous improvements in telephonic apparatus during the past decade were to be seen. In the department of measuring instruments the exhibits testified to the great progress of recent years. The British, Italian, and German sections contained a number of interesting displays, Germany being particularly prominent in electro-chemistry.

New Single-Phase Alternating-Current Motor.—The development of the single-phase alternating-current motor has for a long time engaged the attention of Mr. E. S. Pillsbury, an American engineer, who, after introducing several improvements upon the motor originally patented by him, has recently evolved another design. The special features of his earlier type consisted of the combination of a progressively-wound armature with a slot-wound field, in such a manner that it started as a series motor. After the machine had acquired the proper speed, the brushes were moved away from the commutator, connected together, and simultaneously the winding on the armature short-circuited, after which the motor ran purely as an induction motor. These motors were also provided with a short-circuited winding on the rotor, to prevent it from going above synchronism in case the operator failed to throw the lever at the proper time. In the latest design the motor is so constructed that in starting, instead of the secondary current induced in the armature or secondary member being commutated, the current supplied to the field or primary member is commutated. This makes it possible to employ larger and heavier conductors in the



armature or secondary member in place of the fine-wire conductors heretofore employed, the armature thus being rendered more substantial, of lower resistance, and smaller self-induction, and it will carry a greater load than an armature provided with the fine-wire windings. The armature is thus less susceptible to changes in frequency, and capable of withstanding a greater overload. The *Electrical World* of New York gives the accompanying diagram illustrating the action of the motor. After it has attained the proper speed, the governor weights, 50, operate a cam, 55, which transmits motion for throwing off the brushes and short-circuiting the commutator on the armature, and at the same time making four connections in field coils diametrically opposite. The second

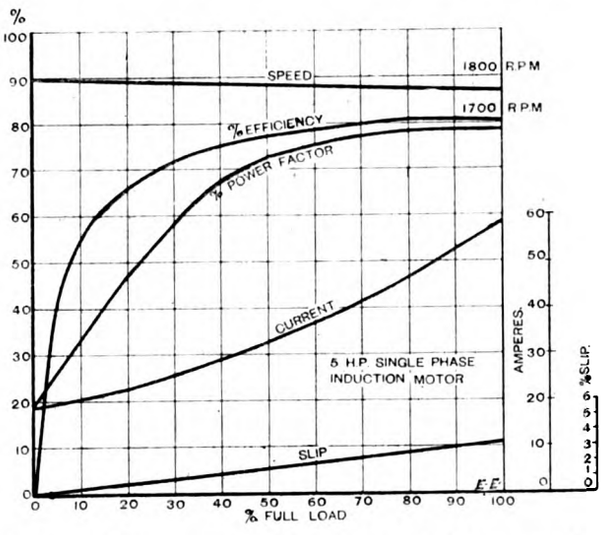


diagram gives curves plotted for a 5-h.p. machine, showing the efficiency and power factor, current consumption, speed, and slip. In developing this motor commercially, the Century Electric Company, of New York, with which the inventor is associated, has departed somewhat from the details shown in the above illustration, in order to combine simplicity with high efficiency.

THE HULL CORPORATION TELEPHONE SYSTEM.

The formal opening of the Hull Corporation telephone system took place this week, and Hull now is the fifth town working a municipal exchange. The history of the starting of the undertaking is a long one, extending over some five years, but throughout that time the Corporation have exhaustively considered every method of avoiding the duplication of the telephone equipment within the town. The object of the Hull Corporation in establishing a municipal telephone service was twofold—first, to provide a much cheaper service, and, so place telephones within the reach of a larger number of users, and second, to introduce a more efficient service. The question was first considered by the City Council in the latter part of 1899, prior to which there was considerable dissatisfaction expressed in Hull, both as to the cost and working of the existing telephone service. Upon the passing of the Telegraph Act, 1899, a petition was presented to the City Council by shipowners, merchants, and traders, bearing upwards of 800 signatures, urging the Corporation to establish a municipal service in Hull, and on Nov. 9, 1899, the Council were entered into with the existing company, with a view to the Corporation acquiring the company's system in Hull, but as the lowest price required would have precluded the Corporation giving a cheaper service, no satisfactory arrangement for purchase could be made.

Negotiations for purchase having failed, the Corporation then endeavoured to arrange with the company for a substantial reduction of their rates, on condition that the Corporation did not enter into competition, but they were unable to induce the company to agree to such rates as would have been acceptable. The negotiations above referred to extended over a considerable period, and have delayed the carrying out of the work, but the Corporation felt they would not be justified in going to the cost of laying down a duplicate system until they had exhausted every effort to avoid it by obtaining, if possible, satisfactory terms from the existing company. One important result, however, of the negotiations with the company must be mentioned—viz., that an arrangement was made by which the Corporation subscribers have free intercommunication with the subscribers of the National Telephone Company, both in Hull and in other towns. The Corporation of Hull had the advantage in these negotiations of having already

FIG. 1.—The Hull Corporation Telephone Exchange.

appointed a special committee to consider and report as to the desirability of doing so.

In order to ascertain the cost for which a municipal service could be provided, the committee consulted the well-known telephone engineer, Mr A. R. Bennett, M.I.E.E., and after a careful enquiry came to the conclusion, in November, 1900, that the establishment of such a service was desirable, and their conclusion was adopted by the Council. Before taking any steps, however, to carry the resolution into effect, a circular was issued to, and a canvass made of, likely subscribers, so as to make certain that a sufficient number of persons were prepared to avail themselves of a Corporation service at the rates offered, the result of which was in every way satisfactory. Resolutions in favour of the scheme were also passed by the Hull Chamber of Commerce, the Hull Guardian Society, the Hull Chamber of Trades, and other trading bodies. The Corporation applied to the Postmaster-General for the necessary license, which was opposed by the National Telephone Company, but, notwithstanding such opposition, the license was granted in August, 1902. The Corporation were anxious to avoid, if possible, the cost of laying down a duplicate telephone system, and accordingly negotiations given the National Telephone Company underground wayleaves under an agreement which could, we understand, be terminated. The company tried to get the House of Lords to break this agreement without success, and the matter was finally settled on the above lines—*i.e.*, there is free intercommunication between the two systems, and, at the same time, the underground wayleaves granted by the Corporation to the company are extended for the period of the telephone license.

Having decided to commence, working tenders were advertised for, and the total of the accepted tenders proved to be less than Mr. Bennett's estimate. The successful tenderers were as follows: W. T. Henley's Telegraph Works Company, cables and street work; Ericsson Bell Company, switchboard and instruments; International Electric Company, lightning and high-tension guards; Messrs. Bolton and Co, copper wire; Electrical Company, bronze wire; British Insulated and Helsby Cables, Limited, insulators; Messrs. Wade and Co., of Hull, poles; Hart Accumulator Company, accumulators; General Electric Company, primary batteries.

The exchange is situated in the building known as the Trippett Baths, which belong to the Corporation, and were

Digitized by Google

being closed through the equipment becoming obsolete. This building, with alterations, was admirably adapted for telephone work.

The alterations to the building were carried out under the supervision of the city architect, but the building (Fig. 1) has been unaltered exteriorily. The upper floor is used as the exchange switchroom, as shown in Fig. 2, while the cable terminals are in the basement. The test frames (Fig. 3), with the high-tension and lightning guards, are also placed in the basement, close to the end of the underground cables. As will be gathered from the above list of contractors, the wires in Hull are chiefly underground. The final distribution, however, is carried out with overhead wires from terminal posts at the ends of the underground mains. The street work involved 19 miles of trenching, in which have been laid 35 miles of Sykes earthenware ducts. The Henley cables used are of the dry-core paper type, lead-covered, and the largest size contains 624 wires. Air pressure is kept on these cables by means of an air-pump of the Reavell type, which is driven by gearing by a B.T.H. motor. The air forced into the cable is first passed through a number of calcium chloride dryers. These underground cables, which enter the main building from two directions, terminate in pot-heads which contain the joints between the paper-insulated wire and the vulcanised indiarubber covered wires which are carried up the frames shown in Fig. 3.

The cables from the switchboard terminate on the test jacks, and the cross-connecting is done by means of asbestos-covered wires. Situated in the testroom is also the power switchboard fitted with the switches, volt and ammeters, and other necessary apparatus for charging the accumulators by means of a motor-generator. The accumulators supplied by the Hart Accumulator Company are in duplicate, and a pair of heavy leads run from the switch on the power board to the switchroom, by means of which either set can be used for supplying current to the exchange. The pair of leads in the switchroom are then branched off to the operators' telephones, pilot lamps, calling, clearing, and other circuits, through retardation coils and lamp resistances, the operators' telephones being shunted by two microfarad condensers. Primary cells are used for the speaking, the accumulators supplying all other circuits.

The switchboard design and connections are of a new type, worked out by the consulting engineer, and a description of the same is shortly to be given before one of the engineering societies, hence we are not publishing a technical description of the same at the present time. The whole of the work has been carried out under the supervision of Mr. Thomas Holme, who was appointed manager in the middle of January. It is an evidence of the energy of all concerned, from the consulting engineer to the contractors, that while work was only commenced then, there are now over 700 subscribers actually connected and working. The switchboard has accommodation at present for 2,000 subscribers, but it is designed so that it can be extended afterwards to provide for 5,000 subscribers. This extension is likely to be needed shortly, as already no less than 1,800

names are on the Corporation books. Besides the exchange in Hull, a small exchange has been opened in Hessle, one at Cottingham will be open in a few days, and another is being organised at Beverley. The Corporation telephone

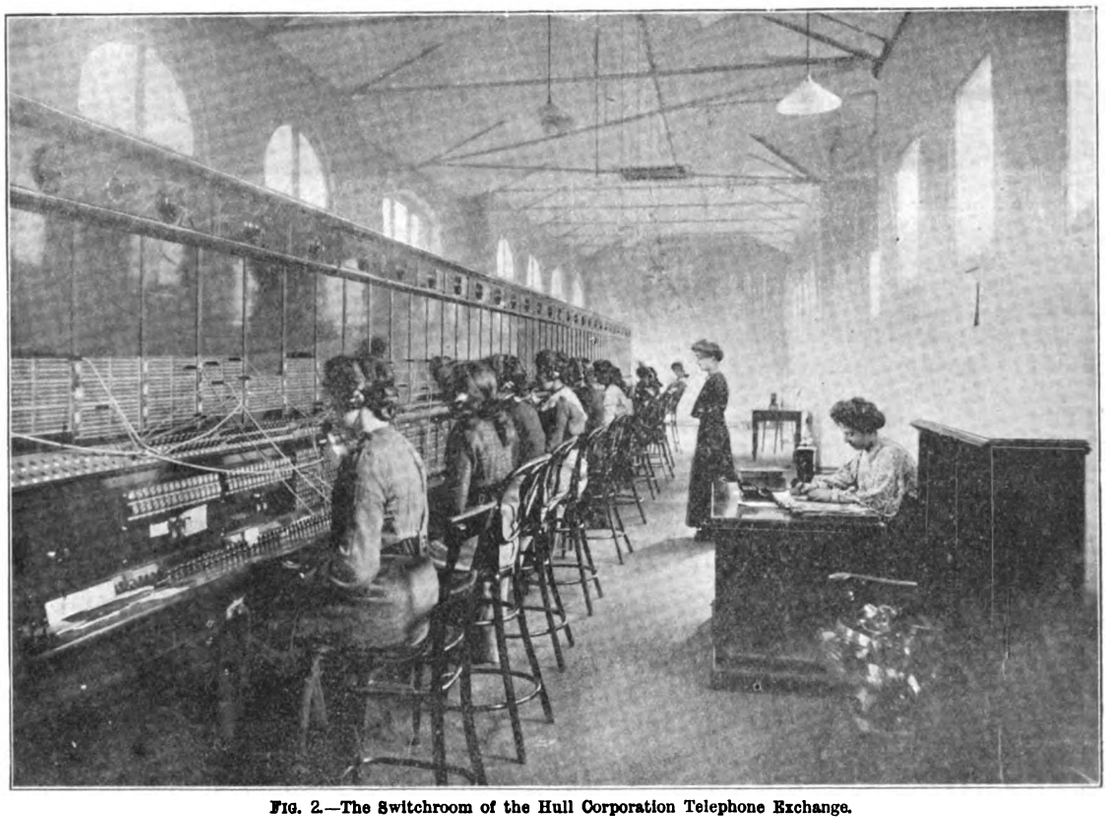

FIG. 2.—The Switchroom of the Hull Corporation Telephone Exchange.

area is a fairly large one, and is the same as that controlled by the license of the National Telephone Company.

As regards the financial side, the Corporation have the sanction of the Local Government Board to borrow £43,202 for carrying out the work. The local enquiry, after which this sanction was obtained, lasted four days, and was as remarkable for the disinterested nature of the opposition as most telephone enquiries in this country. It seems to us, however, that the Hull Corporation, with their free intercommunication with the company, are less likely to cause that wasteful competition which has been met with in other towns. There can be no need for a small subscriber to join both systems, and there is no opportunity for the practice of boycotting which unfortunately has prevailed in some other towns. The tariff adopted by the Corporation should be a remunerative one, and provide amply for capital charges and contingencies. It is as follows: Exclusive line, unlimited use for business premises, £6. 6s. per annum; second connection, £5. 15s. Special quotations for large users. Exclusive line, unlimited use £5 per annum for private houses. Exclusive line, toll-rate £3 per annum, and 1d. per outward call; all inward calls free. Extension instrument in the same building as exchange line, 20s. per annum. Desk sets, 5s. per annum extra.

The opening ceremony on Monday last was a most successful one. The guests assembled in the town hall, and then drove in cabs through some of the principal streets on their way to the exchange. There Mr. Councillor Brown, the chairman of the Telephone Committee, was presented by the Mayor with a golden key with which to open the door. Having entered the building, a similar gift was handed to the Mayoress to open the door of the switchroom. The working of the exchange was then explained by the consulting engineer to the Corporation, Mr. A. R. Bennett, and the whole of the equipment was open for inspection. Our description of this equipment is given above.

After returning to the town hall the guests were entertained by Mr. Brown, and the following toasts were proposed. The CHAIRMAN gave "The King," and then Mr. THORNTON-VARLEY proposed "Success to the Undertaking." He said he had no fear that the Hull Corporation would sustain any loss in consequence of the charge of six guineas for unlimited service. He based his views on the prices which elsewhere had proved remunerative. He did not think that competition, however severe, would be injurious to either party. In Glasgow, for instance, before the municipal system was introduced there were only 5,000 subscribers. To-day the municipal system had 12,000 subscribers, and with the National subscribers there was a total of 25,000. Then it must be remembered that in Glasgow there was no intercommunication, as there was in Hull, where anybody taking either service had the

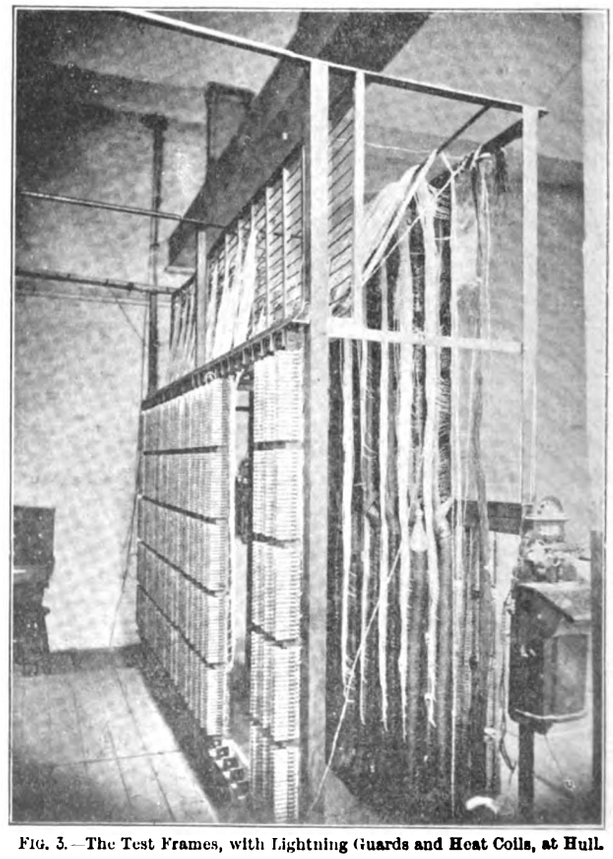

FIG. 3.—The Test Frames, with Lightning Guards and Heat Coils, at Hull.

Digitized by Google

advantage of both. In Hull, too, the municipal system was a perfectly secret system. Directly a subscriber was put into communication with his correspondent nobody else could hear the conversation.

Mr. J. BROWN, the chairman, in reply, advocated the carrying out of telephone work by corporations because it was essentially a local service. According to their returns, with 2,000 calls per day 98½ per cent. were local calls, and only 1½ per cent. were trunk calls. The Corporation had the power to charge under their license anything from £5 to £10 for unlimited service. They had, after consideration, adopted the £6. 6s. rate, which he thought would be found high. It was better to start high and reduce than to have to increase after commencing with a low charge. Mr. Brown also recalled the struggles they had had with the National Company, both to secure better terms and to purchase the exchange in Hull. The price asked, however, for this was about three times that for which they could have put down a new system, and hence his committee could not recommend the Corporation to purchase. They had laid down plant for 2,000 subscribers, and had already 1,800 on their books. Three-fourths of these agreed to pay £6. 6s., and a number of private house connections at £5 had been obtained. They had no subscribers on the party-line system. The company also now offer a £5 service to private houses, and he would remind those who took advantage of this rate that the Corporation had practically saved them £5 per year. He understood that Edinburgh, Liverpool, and other large towns were asking for this lower rate for private houses under the agreement of the National Telephone Company, which enforces them to treat all large towns equally.

The SHERIFF then proposed "The Mayor and Corporation," to which toast the MAYOR replied, upholding the action of the Council in starting telephone competition.

Alderman HOLDER proposed the toast of "The Engineer and Contractors." He said that the contractors were unlike any others he had met with, in that they had completed their work three months in front of time Messrs. Henley's had laid down the mains in the streets, for which 19 miles of excavation were required, at the rate of one mile per week. The people of Hull thus had the advantage of a working system quite three months before contracts were expected to be completed. Alderman Holder also spoke of Mr. A. R. Bennett in very appreciative terms. Although much had been written and said against Mr. Bennett personally and against his skill as a telephone engineer, they at Hull had every confidence in him as their consulting engineer from the first, and this confidence was justified by the work being carried out at considerably under estimated prices. They had also in their secret system a better telephone system than was estimated for in the first instance.

Mr. A. R. BENNETT, in reply, thanked Mr. Holden and those present for their kindness, and gave credit to the local staff under Mr. T. Holme, and to the contractors for the successful completion of the work.

Mr. MCMILLAN, of the Ericsson Bell Company, replied on behalf of the contractors.

The proceedings terminated with a vote of thanks to Councillor Brown as host.

NOTES ON MOTOR-STARTING SWITCHES.

[CONTRIBUTED.]

(Continued from page 727.)

For crane work series motors are usually installed, and as these must be reversible, a special form of switch is necessary. In order to obtain a movement in either direction the current must be reversed in either the armature or the fields, but not in both: it is usual to reverse the direction of the flow through the armature only, and insert the starting switch between the end of the field winding and the armature terminal. While a switch with metallic resistance is often used for crane work, it is more generally found that a liquid switch is used for this purpose. The reason for this appears to be on account of the majority of cranes being used in shipbuilding yards, foundries, engineering works, etc., where, owing to the rough usage which all the equipment may be subject to, the liquid switch is the one more frequently met with for every type of motor.

A very good type of liquid switch is the one now made by Messrs. Steel, Peech, and Tozer, Limited, and which is diagrammatically illustrated in Figs. 12, 13, 14. From these figures it will be noted that the main contact is made for the armature circuit between a central ring and either an inner and outer ring, the central ring being divided into

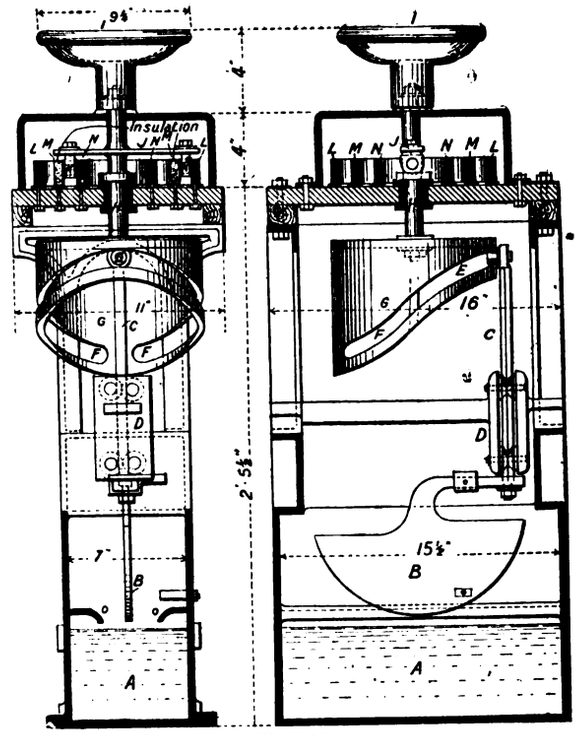

FIG. 12.

two portions so as to permit of a reverse motion being obtained. At the two points where the central ring is cut the space is filled up with an insulating material, and when the contact pieces are brought into this position the motor armature is entirely disconnected from the feeders. The motion of the contact pieces is controlled by a hand-wheel fixed to a vertical shaft; on this shaft is mounted a cylinder in which is cut a crescent-shaped groove in which works the roller fixed to the upper part of the guide rod of the resist-

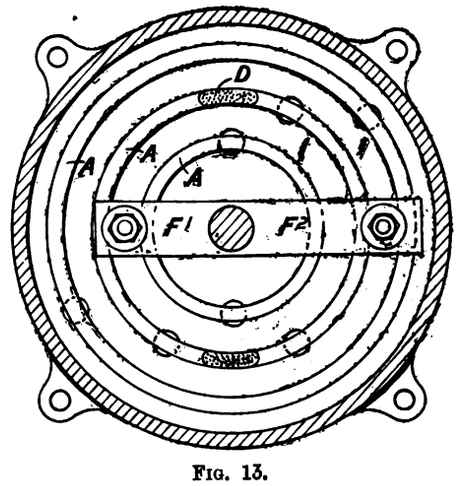

FIG. 13.

ance plate. The whole is so arranged that when the contact pieces are brought against the insulating piece of the middle ring the resistance plate is entirely out of the water, but as the contact pieces are moved in either direction the plate becomes immersed in the liquid. This arrangement is simple and effective, while at the same time it permits of a strong and well-protected switch being built suitable for withstanding the rough usage that switches too frequently receive in shipbuilding yards and engineering works generally. Up to the present this type of switch has only

Digitized by Google

been made for operating series-wound motors, but there is nothing to prevent the switch being adapted for shunt or compound wound motors.

It is difficult to arrange a suitable automatic no-volt release in connection with a liquid switch, and the omission of this is the only fault that is apparent in the details of the above switch. This defect can only be overcome by inserting a no-volt circuit breaker in the motor leads; this naturally increases the cost, but greatly improves the installation, and the money so spent is well expended.

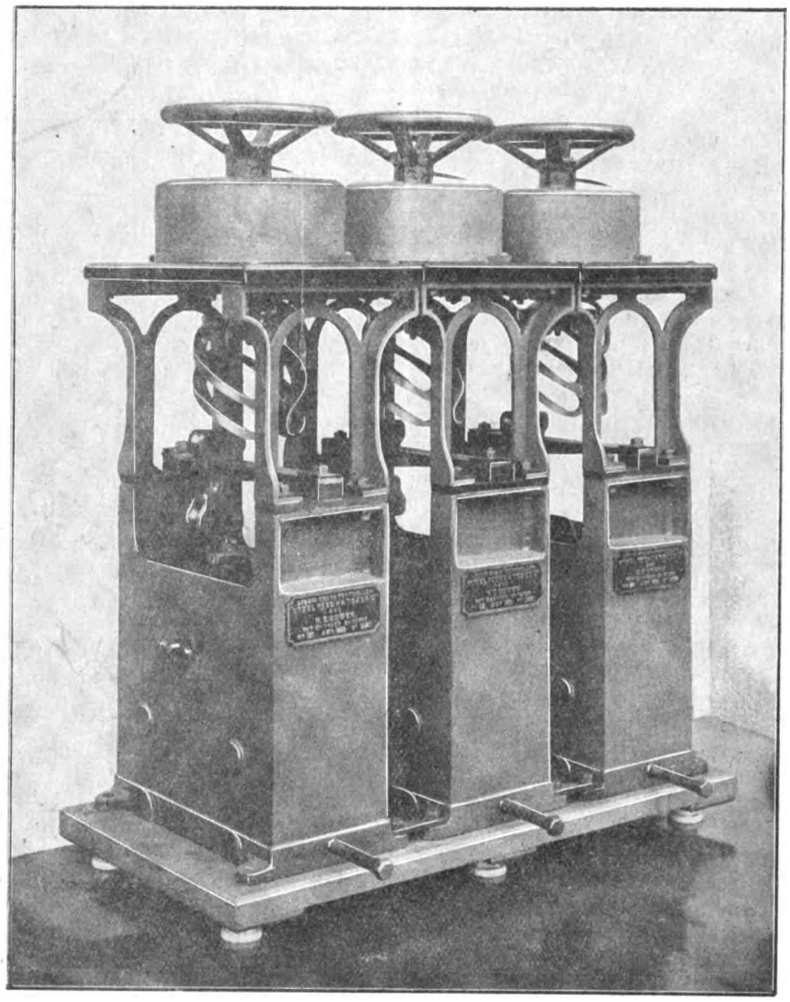

FIG. 14.

In dealing with the ordinary wire resistance starting switches, one of the points of greatest importance, whatever type of switch is used, is that of the durability of the resistance wire. If these short-circuit on themselves or to the frame, or if they burn out, continual trouble is experienced. The two points, then, that should receive the greatest attention with regard to the resistance wire are, first, the class of wire employed, and, secondly, the method of attachment. Innumerable materials, such as plain iron wire, galvanised iron, reostene, and other special alloys, have been employed by different makers, and it is difficult to say which metal has given the best results. Where the switches are to be fixed in a humid atmosphere, the iron wire rapidly rusts, and therefore in such cases it is advisable to use a metal, such as German silver, that does not oxidise rapidly; but when the switches are to be used in a dry atmosphere, the use of iron wire has been found to give very good results. It is generally considered that the object of the sand in which the wires are embedded in some makes of starting switches is to keep the resistance coils from short-circuiting either on themselves or on the frame. This is not, however, the case, and the real object

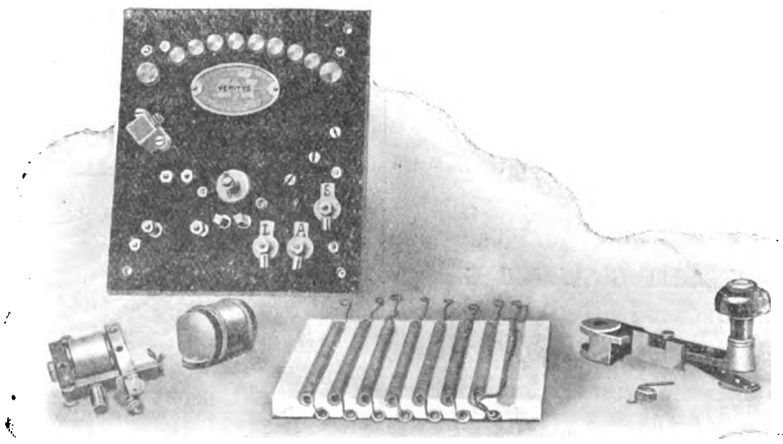

FIG. 15.

Digitized by Google

of the sand is to absorb the heat generated in the wires. As a matter of fact, the sand affords little mechanical protection, as if there is any vibration the sand will give way, and also in the case of the wires tending to sag they will push the sand on one side. In Fig. 15 is illustrated a neat arrangement devised by Messrs. Veritys, Limited, to secure freedom from short-circuiting in their newer types of starting switches. It will be noted that the various coils are carried on the two sides of an independent fireproof support. This support is channelled out so that each coil lies in a separate groove, and is firmly held in its position. The firm claim that this method of construction provides perfect immunity from any chance of short-circuiting, while at the same time should any coil from any accidental cause break down it can be easily replaced, as there is not a single soldered joint used in the construction, but the various coils are fastened together by means of special connectors. The only other point that calls for attention is the fact that all the parts are removable from the front, and so can be replaced, if necessary, without taking the switch down from its position. The method of securing the coils, however, is good, and should give satisfactory results in practice.

To be continued.)

THE MEASUREMENT OF THE POTENTIAL OF THE ELECTRODES IN STATIONARY LIQUIDS. THE DETERMINATION OF CHANGES OF CONCENTRATION AT THE CATHODE DURING ELECTROLYSIS.*

BY HENRY J. S. SAND, PH.D., M.SC.

(Concluded from page 665.)

Alcoholic Solutions of Cuprous Chloride.

The next series of determinations was carried out with the object of testing whether the method was suitable for alcoholic solutions. The solution chosen was one of cuprous chloride in a mixture of hydrochloric acid, alcohol, and water, its composition being 1 grm. Cu_2Cl_2, 25 cubic centimetres strong hydrochloric acid, 45 cubic centimetres 95 per cent. alcohol, 30 cubic centimetres water. Owing to contact with the air, part of the cuprous chloride became oxidised to cupric chloride. The curves on Fig. 6 show the degree of coincidence obtained in successive experiments, three determinations having been carried out with the current density 1·054 $\frac{\text{milamps}}{\text{cm.}^2}$, and two with the current density 1·318 $\frac{\text{milamps.}}{\text{cm.}^2}$. The curves obtained are of interest, inasmuch as they show plainly that two successive processes take place: firstly, the reduction of the cupric chloride to cuprous chloride, which begins at potentials lower than those registered in the figure, and goes on to about 45 centivolts; and, secondly, the deposition of copper from the cuprous chloride beginning at about 45 centivolts and going on until the break in the curve is completed, when the potential becomes fairly constant at about 65 to 70 centivolts, and hydrogen comes off.

Acid Solutions of Nitrobenzene.

We now come to the discussion of curves obtained when the solution of an organic substance—namely, nitrobenzene—was reduced under varying conditions. Two solutions were experimented upon with different electrodes and current densities, other conditions remaining unchanged as nearly as possible. Stock solutions of accurately known composition were mixed in known proportion, the composition of the resulting liquids working out as follows:

1 litre acid solution used for experiments of Figs. 7, 8, 9, 10, contains	5 grm. nitrobenzene. 107 grm. H_2SO_4. 425 cc. ethylalcohol. Remainder water.
1 litre alkaline solution used for experiments of Fig. 11 contains	5 grm. nitrobenzene. 82 grm. NaOH 425 cc. ethylalcohol. Remainder water.

The anode for the experiments on acid solutions was, as as rule, one of copper in contact with a solution of 30 grm. cuprous chloride in 200 cubic centimetres strong hydrochloric acid and 100 cubic centimetres 95 per cent. alcohol. For the experiments on the alkaline solution the anode was mercury in contact with a solution of 100 grm. mercurous

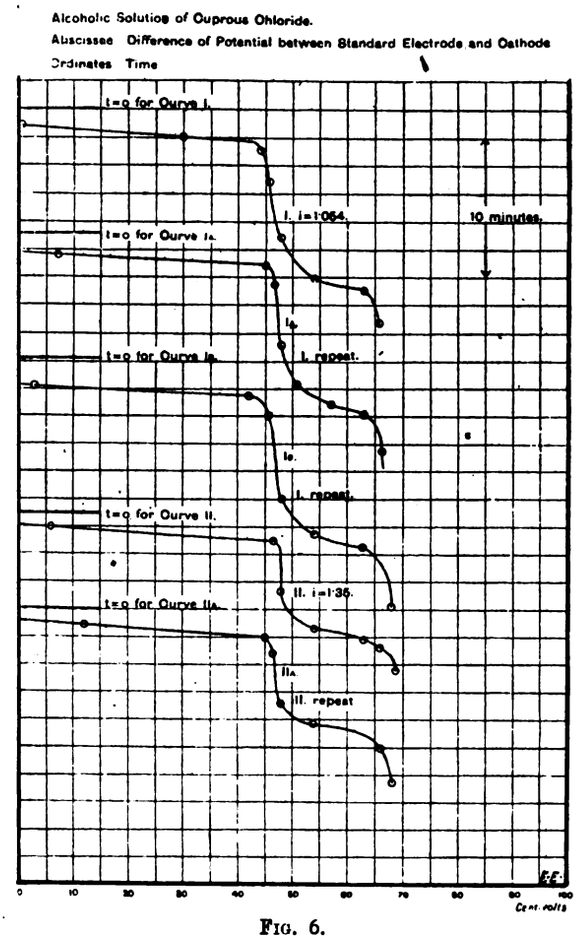

FIG. 6.

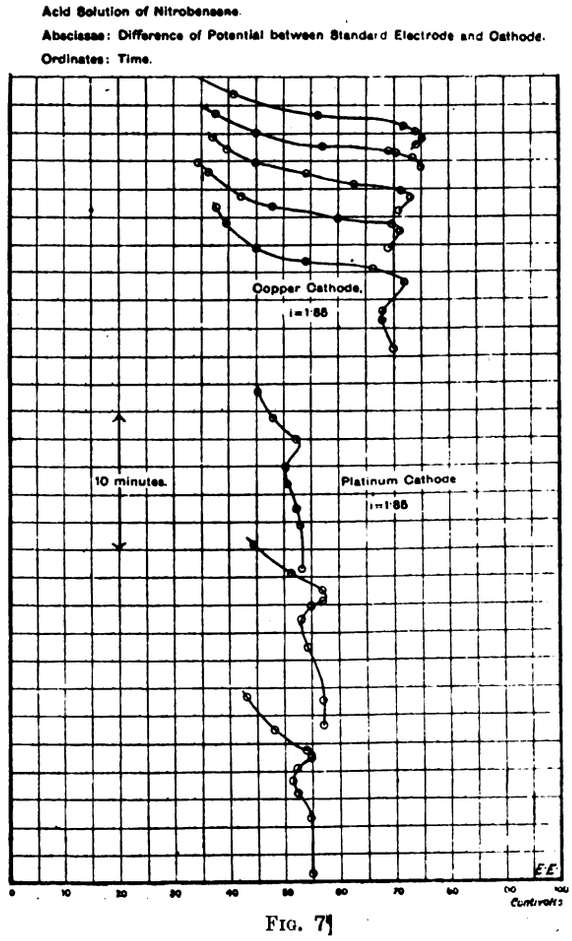

FIG. 7.

* Paper read before the Faraday Society, Oct. 25, 1904.

nitrate and 35 cubic centimetres strong nitric acid in 500 cubic centimetres water, the solution interposed con-

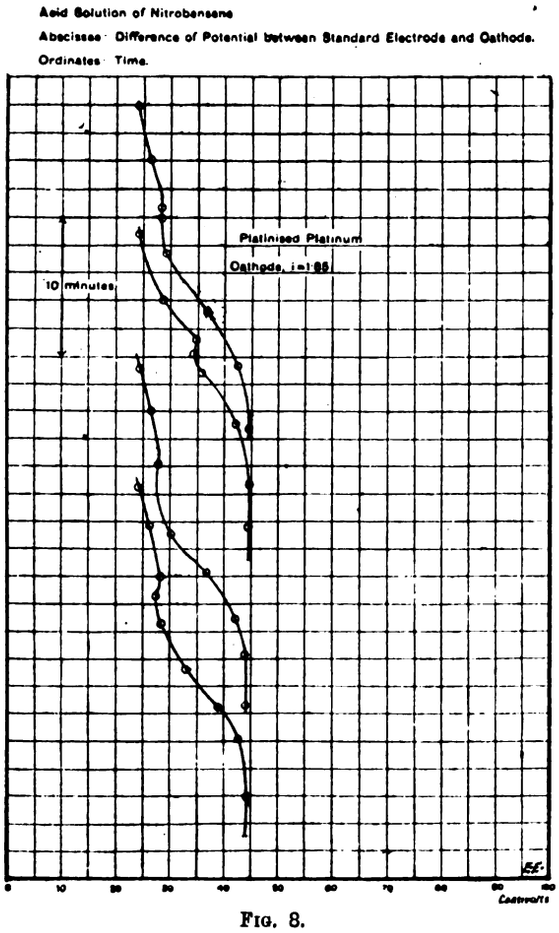

FIG. 8.

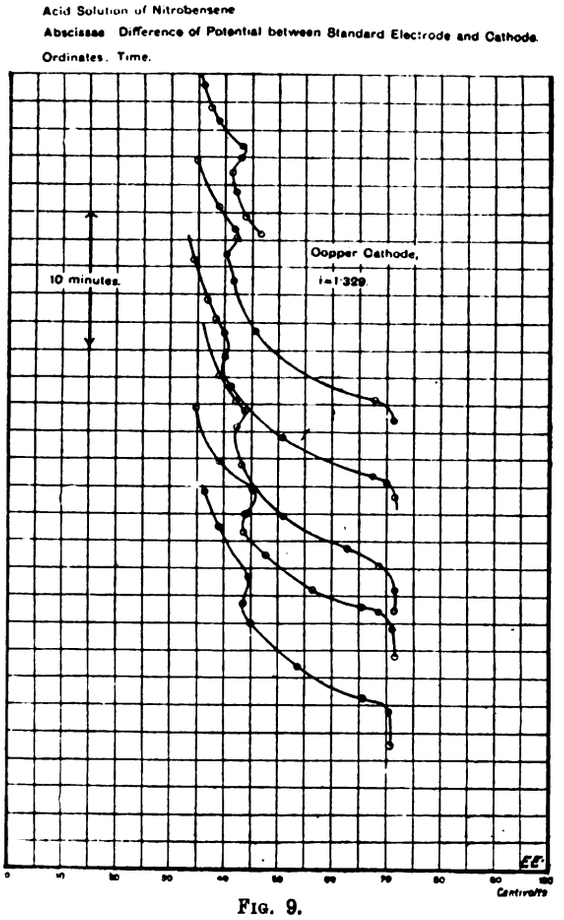

FIG. 9.

taining 125 grm. ammonium nitrate in 500 cubic centimetres.

The curves obtained show, firstly, the degree of coincidence yielded by a repetition of experiments, and, secondly, they exhibit both interesting similarities independent of the material of the electrode and characteristic differences due

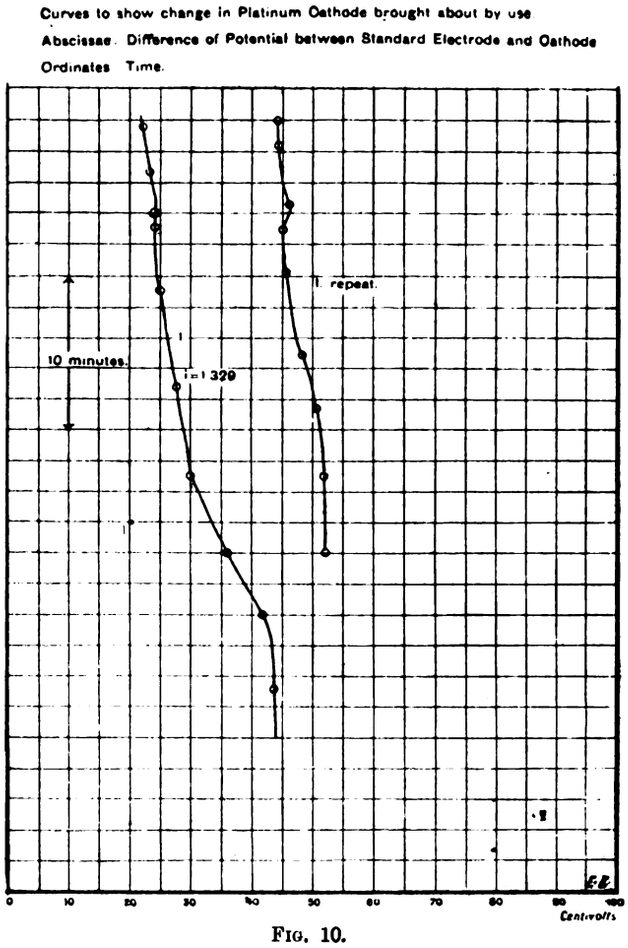

FIG. 10.

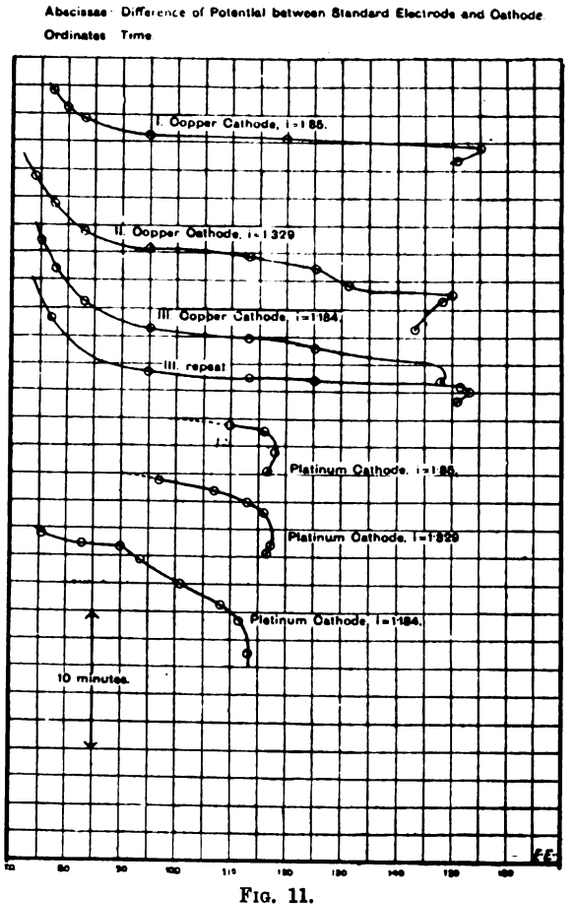

FIG. 11.

to it. The abscissæ again denote the experimentally found values of the potential of the standard electrode, the potential of the cathode being taken as zero. A small correction may be made for the difference of potential due

Digitized by Google

to the resistance overcome by the current between the cathode and the junction, T, by taking the value 3½ ohms for this resistance in the case of the acid solution, and six ohms for the alkaline solution. All the curves representing the results of experiments on acid solutions exhibit first a rise of potential. After this it recedes, or becomes almost stationary, then increases once more, and finally becomes stationary again. Bubbles of hydrogen may now be observed on the cathode. It may, perhaps, be premature to attempt to explain definitely the first retrogression of potential in the curves. The most probable cause seems to be a temporary change in the nature of the electrode, resulting from electrolysis. Such changes have been recently shown to occur frequently by Russ, Luther, and Brislee, and others. As a rule, they tend to make cathodes more efficient—*i.e*, they enable them to accomplish reduction with the expenditure of a smaller amount of energy. The electrodes are also certainly permanently changed under certain conditions in such a manner that they become less efficient. This is very notable with the cathode of smooth platinum when small current densities are employed. If an electrode is used which has been freshly cleaned with ligroïn, boiling strong nitric acid, and boiling caustic soda solution, the potential of the standard electrode shows a comparatively low value throughout the experiment, the results being similar to those obtained with a cathode of platinum coated with platinum black. On repetition the cathode is, however, found to have become less efficient, the potential being considerably higher than in the first experiment. Further repetitions yield curves almost identical with the second, the potential, however, still becoming slightly higher. When the cathode is cleaned after this, as before the first experiment, it again yields a curve similar to the first. In Fig. 10 the first curve and one of its repetitions are shown.

Fig. 7 illustrates results obtained with a copper and a platinum cathode respectively. The experiments with the copper cathode were stopped after the first retrogression of potential. It will be seen that the latter occurs approximately at the same time in the experiments with the copper as in those with the platinum electrode. The difference between the actual values of the potentials is, however, very marked, the standard electrode at the beginning of the copper experiments showing a lower value than at the beginning of the platinum experiments. This corresponds to a greater efficiency—*i.e.*, a smaller expenditure of energy in the case of the copper than in that of the platinum electrode. In accordance, however, with the greater E.M.F. required for the liberation of hydrogen on a copper cathode than on one of platinum, the copper curves attain higher values of potential than the platinum curves at the end of the experiment. Fig. 9 represents experiments with a copper cathode carried out until evolution of hydrogen takes place. In Fig. 8 results are shown obtained with an electrode of platinum thickly coated with platinum black, the current density being the same as in the experiments of Fig. 7. The low values of the potential represent the most conspicuous feature of these experiments. As the electrode is not smooth, the time values are not comparable with those of Fig. 7.

Alkaline Solutions of Nitrobenzene.

Fig. 11 represents results obtained with the alkaline solution of nitrobenzene. As the solution at the cathode becomes heavier during electrolysis in an alkaline electrolyte, owing to an accumulation of alkali, the cathode was placed horizontally at the foot of the cell in these experiments (Fig. 2). At the points of maximum voltage hydrogen begins to be evolved. The differences between the experiments with copper and platinum electrodes are similar to those observed in acid solution. The time which elapses until hydrogen is evolved by a current of given density is considerably smaller than in acid solution. This points to the conclusion that the diffusion coefficient of nitrobenzene is considerably smaller in alkaline than in acid solution, and possibly also that the reduction does not proceed quite so far before hydrogen is evolved.

Example of Application of Results.

In conclusion, we have to show how experiments carried out according to the method described may be employed in order to arrive at an estimate whether results that have been obtained in electro-chemical investigations are due simply to concentration changes at the electrode that take place so rapidly that they cannot be neutralised by stirring, or whether they are really properties of the solution originally made up by the experimenter. As an example, we shall investigate whether concentration changes can have taken place during the experiments by Haber, referred to in the introduction, with sufficient rapidity to explain his results. We may approach such questions from two points of view. Firstly, we may make an arbitrary assumption regarding the time that must elapse until artificial stirring can completely renew the layer of liquid touching the electrode. For example, we might assume that such a renewal takes place completely after the lapse of one second, or of one minute, and then calculate what is the maximum change of concentration that can have taken place. Secondly, we may assume that owing to stirring the concentration of the electrolyte is always left unaltered at some definite distance, say $\frac{1}{10}$mm., from the electrode, and then calculate the maximum change of concentration that is conceivable on this assumption. Proceeding on the first plan we have the equation

$$C = C_0 - 2F\sqrt{\frac{t}{\pi k}} \quad . \quad . \quad . \quad . \quad (1)$$

in which C_0 is the original concentration of the substance electrolysed, C its concentration after the time t, k its diffusion coefficient, and F the amount removed by electrolysis at the electrode per unit of surface and time. From this equation we find the following value for the relative change of concentration at the electrode:

$$\frac{C_0 - C}{C_0} = \frac{2F}{C_0}\sqrt{\frac{t}{\pi k}} \quad . \quad . \quad . \quad . \quad (2)$$

Proceeding according to the second plan and indicating the distance from the electrode at which no change of concentration takes place by δ, we have the following relation according to Fick's diffusion law:

$$F = k\frac{C_0 - C}{\delta},$$

from which we obtain for the relative change of concentration at the electrode the value

$$\frac{C_0 - C}{C_0} = \frac{\delta F}{k C_0} \quad . \quad . \quad . \quad . \quad . \quad (3)$$

When the current is employed solely for reduction we have

$$F = \frac{i}{96{,}540} \quad . \quad . \quad . \quad . \quad . \quad (4)$$

concentrations being expressed in g.-equivalents or mg.-equivalents per cubic centimetre, and current densities in amperes per square centimetre or milliamperes per square centimetre respectively.

In order to eliminate k from these equations, we may calculate its value from the experiments we have described in the present paper. For this purpose we must assume that nitrobenzene has been completely removed from the electrode by reduction to azoxybenzene when hydrogen is evolved. We then find k by applying equations (1) and (4) to our experiments. We thus obtain

$$k = \left(\frac{2i'}{96{,}540\, C_0}\right)^2 \frac{t'}{\pi} \quad . \quad . \quad . \quad . \quad . \quad (5)$$

quantities referring to our experiments being distinguished by dashes. The values for k derived from this equation are no doubt often vitiated by the fact that hydrogen may come off before complete reduction of the nitrobenzene has taken place, so that the values found for k are too small, and those for $\frac{C_0 - C}{C_0}$ too large. This does not matter seriously, however, as we only desire to find an upper limit for the latter quantity. Eliminating F and partly k from the equations (2), (3), (4), (5), we find the following relations:

$$\frac{C_0 - C}{C_0} = \frac{i}{i'}\frac{C_0}{C}\sqrt{\frac{t}{t'}} \quad . \quad . \quad . \quad . \quad (6)$$

Digitized by Google

and $$\frac{C_0 - C}{C_0} = \frac{i}{96{,}540} \frac{\delta}{k C_0} \quad . \quad . \quad . \quad . \quad (7)$$

As an example, by which to test whether concentration changes played an important part in Haber's results, we take numbers from the paper recently published by him in conjunction with Russ. According to Table II., p. 279, when a current of density $\frac{4{\cdot}5}{1{\cdot}5 \times 10} \frac{\text{milamps.}}{\text{cm.}^2}$ was passed through a vigorously stirred alkaline solution of nitrobenzene of the concentration 0·8 $\frac{\text{mg.-equiv.}}{\text{cc.}}$, an absolute potential of 0·0737 volt was observed; whereas when the current had a density of $\frac{36}{1{\cdot}5 \times 10} \frac{\text{milamps.}}{\text{cm.}^2}$, the potential was 0·1171 volt, the difference being 0·0434 volt. Now, according to the Table VII*a*., when a current of the density $\frac{5}{1{\cdot}5 \times 10} \frac{\text{milamps.}}{\text{cm.}^2}$ was employed in a solution of the concentration 0·8 $\frac{\text{mg.-equiv.}}{\text{cc.}}$, the potential 0·0993 volt was recorded. In order to obtain a rise of potential of 0·0434 volt by reduction of the concentration of nitrobenzene, the current strength being left unchanged, we can infer by interpolation from numbers given in the same table that the concentration must be reduced to 0·115 $\frac{\text{mg.-equiv.}}{\text{cc.}}$—*i.e.*, to 14 per cent. of its former value. If the first experiments are to be explained as a result of local reduction of concentration at the cathode, such reduction must, therefore, amount to at least 86 per cent.

Now, in order to obtain an estimate of the magnitude of depletion at the cathode that actually took place, we refer to one of our experiments represented in Fig. 11. Taking, for example, Curve 4, we have $i' = 1{\cdot}184 \frac{\text{milamps}}{\text{cm.}^2}$ $t' = 460'$, $C'_0 = \frac{5 \times 3}{123} \frac{\text{mg.-equiv.}}{\text{cc.}}$. Employing equation (6), we find that if the liquid touching the cathode is renewed completely after every second by stirring, the lowering of concentration could never go below 1·4 per cent. I have shown formerly that under more unfavourable circumstances—viz., when the cathode was mercury contained in a cup—it is possible to prevent depletion, which would require 0·4 second if the liquid were stationary. It seems improbable, therefore, that the lowering of concentration in Haber's experiment went below the above value.

By employing equations (5) and (7) we find that if the concentration of the liquid be maintained continually at its original value by stirring at $\frac{1}{10}$mm. distance from the cathode, the utmost lowering that could take place would amount to 5¼ per cent. Brunner calculates the distance from the electrode to which he was able to keep the concentration unchanged in his experiments to have been $\frac{1}{80}$mm. to $\frac{1}{30}$mm., so that, adopting his values, we should conclude that the lowering of concentration did not amount to more than about 1½ per cent. Starting from other curves on Fig. 11, we obtain similar values. In any case the results show that we cannot assume changes of concentration amounting to 86 per cent. to have taken place in Haber's experiments, and that the variations of electrode potential with current density observed by him can therefore not be explained as the result of concentration changes at the cathode.

In carrying out the foregoing investigation the author has been assisted by grants from the Chemical and Royal Societies, for which he desires to express his indebtedness.

THE USE OF IRON IN ALTERNATE-CURRENT INSTRUMENTS.*

BY W. E. SUMPNER, D.SC., MEMBER.

It is probably no exaggeration to state that the amount of time, ingenuity, and skill devoted during the last 10 years to the improvement of alternate-current instruments has exceeded that spent in perfecting those for direct-current measurements during a period more than twice as long. Yet no one will maintain that the result is anything like so satisfactory in the former case as in the latter. It will, I hope, be interesting to spend some time this evening in considering the reasons for this, and what prospect there may be of a better result in the future.

The first idea that will no doubt occur is that alternate-current measurements are more complicated than those with steady currents, and that in consequence the tests are not likely to be so accurate. Now, I believe this view to be entirely wrong. Direct-current measurements, as the result of a development spreading over many years, are really much more numerous and varied, and are certainly quite as intricate in character as those practised in alternate-current working. It is not so much in the nature of the measurements to be made as in the character of the instruments available for the tests that the difference really lies. The result, I believe, is almost entirely due to the fact that for alternate currents there is no instrument at all comparable in sensitiveness with the galvanometers and voltmeters available for steady current work.

Now, perhaps this idea, though familiar to some, will take others by surprise. But if we proceed to consider how much all good direct-current tests depend upon sensitive galvanometers or voltmeters, we shall, I think, most of us be surprised. Take the three fundamental cases of the Wheatstone bridge, the potentiometer, and the voltameter. In each of these instances the accuracy of the test is directly dependent on the use of a delicate voltmeter to adjust to equality two voltages. In the first case the adjustment is made in order to measure a resistance in terms of a standard. In the second, by means of known resistances, a current or voltage is measured in terms of these resistances and the E.M.F. of a standard cell. In the third case, in which, say, a current balance is being standardised, although the voltameter measurement does not need a voltmeter, the adjustment of the current to a constant value is directly dependent on the use of such an instrument, and this adjustment is just as essential to accuracy as the correct measurement of the amount of chemical action. Measurements of insulation, magnetic induction, and capacity would hardly be possible without delicate galvanometers. Indeed, the sensitive voltmeter seems the one common essential to all accurate electrical testing.

It is of little practical use to speculate as to what would have been the progress of pure and applied electrical science if such instruments had not been available for direct-current testing. But it is hardly possible to overstate the important part they have had in bringing about this progress, and everyone will admit that the precision possible in the design of electrical apparatus, whether for direct or alternate currents, is almost entirely due to accurate measurements made with them. Most of the tests needed in connection with alternate-current machinery are still carried out by direct-current methods.

It is, of course, to the use of permanently magnetised steel that direct-current instruments owe their great sensitiveness. Whether of the fixed-coil or moving-coil types galvanometers may be described as single-current instruments in which the deflecting force is proportional directly to the current or voltage applied. Unfortunately, all alternate-current instruments have the characteristics of the double-current type, in which the deflecting force is proportional to the square of the current or voltage. This is obviously true of dynamometers, current balances, wattmeters, phasemeters, and electrostatic instruments. It is also true of induction instruments, whether the current induces magnetism as in moving-iron instruments, or eddy currents, as in the more recent induction meters. Hot-wire instruments have the same characteristic, since the heating effect varies as the product of volts and amperes. Instruments in which the deflecting force varies as the square of the applied voltage cannot be made sensitive for minute voltages owing to the rapid diminution of the force as the voltage decreases, and this constitutes the main reason why alternate-current instruments cannot be made to indicate low voltages.

Hot-wire instruments are as yet the most suitable for

* Inaugural address of the Chairman, delivered before the Birmingham Local Section of the Institution of Electrical Engineers.

Digitized by Google

measuring small alternating voltages. Commercial instruments can be obtained reading from one volt down to about one-tenth of a volt. Prof. Threlfall has described an instrument before this Institution capable of measuring one-hundredth of a volt, and Prof. Fleming has shown a somewhat similar instrument to the Physical Society of London. Mr. Duddell has recently made an instrument which may be described as a combination of a hot-wire voltmeter with the radiomicrometer of Prof. Boys, the heat from the wire causing a thermo-electric current in a delicately suspended electric circuit placed in the field of a strong permanent magnet. With such an instrument, using as pointer a reflected ray of light, with the scale at 1m. distance, it is possible to get a deflection of more than 1cm. per *microwatt* spent in the hot wire. But such instruments, and especially the last, are more fitted for laboratory and research purposes than for ordinary testing.

An instrument may be made sensitive either by weakening the control or by increasing the forces causing the deflection. The strength of the control is a fair measure of the suitability of the meter for ordinary commercial work, since the weaker the control the more tenderly must the instrument be used, and the more liable are its indications to be affected by extraneous influences. The true measure of the sensitiveness (except for research purposes) is, therefore, the turning moment exerted per unit of current or voltage applied. Now, it is generally stated that a galvanometer of the fixed-coil or Thomson type is more sensitive than the moving-coil form of instrument; but this is merely due to the fact that the control used can be made, and is made, much weaker in the former than in the latter case. With equally strong control the permanent magnet form of instrument is much the more sensitive of the two, owing to the strength of the field applied to the coil conveying the current to be measured. In order to make alternate-current instruments as sensitive as the corresponding direct-current ones, strong magnetic fields must be produced. The permanent magnet is useless for alternate-current work unless satisfactory instruments of the vibration type can be devised, but the electromagnet, the most powerful form of magnet, still remains a possibility. Electromagnets are not used in galvanometers because existing instruments are sufficiently responsive, and thus only when extreme sensitiveness is needed—as, for instance, in the oscillograph—is anyone willing to put up with the inconvenience of supplying a subsidiary magnetising current and maintaining it of constant strength. The problem of producing sensitive alternate-current instruments resolves itself, therefore, into an enquiry into the conditions under which iron-cored electromagnets may be introduced into such instruments without involving errors due to differences of phase, frequency, wave-form, and other disturbing factors.

As an example of the need for more sensitive alternate-current instruments, I may instance the important problem of directly measuring an alternate current, or voltage, in terms of direct-current standards, such as a known resistance, and the E.M.F. of a standard cell. As yet the only standards available for alternate-current work are of a secondary character, and consist of expensively constructed instruments which have been standardised by direct-current measurements. Some years ago I tried to find a means of using the Crompton potentiometer for the direct measurement of an alternate-current voltage in terms of a standard cell. I soon saw how this could theoretically be done, but I have not succeeded in making or in finding an instrument sensitive enough to satisfactorily carry out the test. It may, however, be interesting, in connection with our subject to-night, to state the method. The problem consists in accurately balancing two voltages each of the order of a volt, the one produced by a steady current and the other by an alternating one. The current or voltage to be measured, whether direct or alternating, can be easily made to produce such voltages with the aid of shunts, or subdivided resistances, in the way commonly used with potentiometers. The direct voltage, D, is produced by the potentiometer, is adjustable by means of the sliding contact, and is accurately known. The alternating voltage should consist of two portions, A_1 and A_2, in series. The ratios of A_1 and A_2 to each other, and to the current or voltage to be tested, are supposed to be accurately known from the shunts or resistances employed. If now one of the terminals of the voltage D be connected to the junction of A_1 and A_2; if a voltmeter of the dynamometer type have its terminals connected to the extremities of the voltages A_1 and A_2; and if the free extremity of D be connected with the junction between the fixed and moving coils of the dynamometer, it will be seen that the voltages on the dynamometer coils are respectively $D + A$ and $D - A_2$.

Thus in Fig. 1 O is the middle terminal, and P Q the extreme terminals of the alternating voltage, $A_1 + A_2$. The direct voltage, D, is connected with the points O and R. The dynamometer coils, *c c*, are joined through suitable non-inductive resistances to the points P R and Q R. Under these circumstances the turning moment exerted on the moving coil is proportional to the product $(D + A_1)(D - A_2)$. This is true for any instant, and thus must be true for the mean. Since D is constant, A_1 and A_2 are alternating quantities, and $A_2 = k A_1$, where k is some known constant, it will be seen that the mean product is $D^2 - k A^2$, where A^2 is the mean value of A_1^2. The instrument, if sufficiently sensitive, will only give zero deflection when $D^2 = k A^2$, or, supposing $k = 1$, when $A = D$. This means that the alternating voltage, A, is measured directly

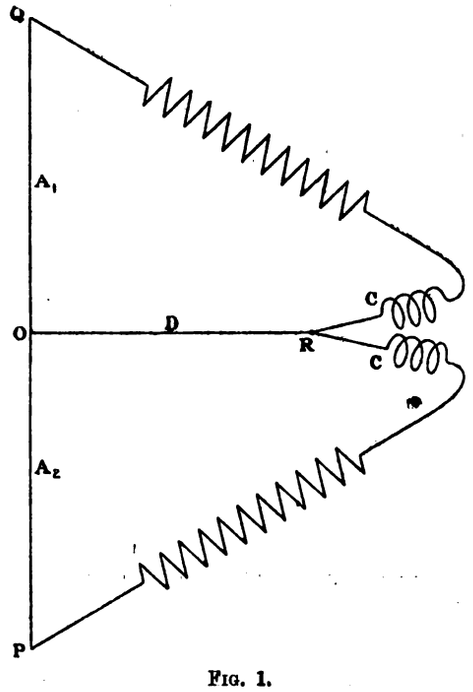

FIG. 1.

in terms of the standard cell, in a manner quite independent of frequency or wave-form. But the method, though perfect in theory, is impracticable, as is also the analogous method represented by interchanging the letters A and D in Fig. 1, in which case the direct-current voltage, D, is sub-divided instead of the alternating one. An instrument of sufficient sensitiveness could only be made by weakening the control to an extent rendering it unsuitable for common use, and the method only appears to be applicable by establishing a subsidiary voltage D, much greater than a volt, balancing it against the unknown alternating voltage, and measuring it immediately afterwards by the potentiometer in the ordinary way. Nevertheless, the mere invention of a sensitive dynamometer voltmeter would at once render the Crompton potentiometer, as now made, as suitable for the measurement of alternating currents and voltages as of the corresponding direct-current quantities for which it is so useful.

Now, before discussing how to use iron in alternating-current instruments, it must first be stated that this is already done in many cases, as in moving-iron indicators and in instruments of the eddy-current type. The latter now form an important class, and are either of the shielded pole type, the outcome of some pioneer experiments of Elihu Thomson, or of the rotary field type due originally to Ferraris. The rotating field instruments are particularly useful. They have the great advantage that the geometrical

Digitized by Google

relations of the fixed and moving parts are not changed as the disc or cylinder turns, so that the indicating instruments possess regularly divided scales, and a range of deflection extending to nearly 360deg. Such instruments have many undoubted merits, but their calibration varies with frequency, and to a slight extent with wave-form. The wattmeters of this class are, indeed, not much more than good indicators. They are not the less useful on that account. They fulfil all the requirements of central-station use, but for accurate measurement something more is needed.

The first instrument to which I wish to direct your attention is the phasemeter, or power-factor indicator. These instruments may be made for either single or multiphase circuits. In the former case the calibration depends somewhat on the frequency, but only very slightly so in the latter. All such instruments consist of a fixed and moving set of coils, having a common diameter about which the moving system turns. The moving system is quite free to revolve. There is no control except that due to the interaction of the currents. Each system may comprise more than one coil, but as a rule the fixed system consists of a single coil through which the current passes, while the movable system consists of two coils inclined at some fixed angle to each other, and traversed by currents in different phases, obtained usually by tapping the multiphase mains, but, in the case of single-phase circuits, by providing two paths of different inductive properties for the pressure currents needed for the coils.

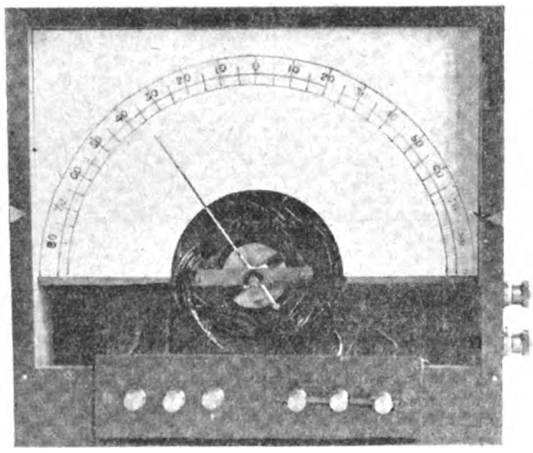

FIG. 2.—Phasemeter, or Power-Factor Indicator.

Now, in the theory of these instruments as hitherto given, the action of the current in the fixed coil on that of each of the moving coils is separately considered. Two moments are exerted, one on each moving coil, and the position of balance indicated by the pointer is such that these moments are equal and opposite. This position is independent of the amperes, or volts, since alteration in either of these equally affects the two moments, so that if these moments are balanced for, say, 20 amperes, they are equally balanced for 30 amperes. The position of balance can, therefore, only depend upon the phase differences between volts and amperes, and hence the deflection of the pointer can be calibrated to indicate phase.

But there is another way of looking at the action which is useful to consider, and which I think has not been previously noticed. The two-coil system traversed by currents in different phase produces a rotating field, and the interaction between this and the alternating (or rotating) field due to the current (or currents) in the other system of coils must be such that there is only one stable position of the moving system of coils for which the torque vanishes, and this position can only depend upon the phase differences involved in the two systems of currents. This is illustrated in rotary synchronisers such as that of Everett Edgcumbe, the rotor and stator of which are each wound so as to produce a rotating field by splitting a single-phase current into an inductive and a non-inductive branch. If two generators are joined up, one to the rotor and the other to the stator, the rotor revolves rapidly if the frequencies are different, but as these approach equality the rotation is slow, clockwise if one machine leads, counter clockwise if it lags; the position of the pointer indicates at each moment the phase difference of the two currents. If the two machines are coupled together so as to generate voltages in fixed phase relation, the pointer attached to the synchroniser takes up a fixed position in correspondence with this phase. The instrument thus becomes a phasemeter, and can be calibrated as such, but in its present form it is not suitable as a power-factor indicator.

Now, imagine a coil traversed by an alternating current placed in a rotating magnetic field of the same frequency, and free to turn about the axis of rotation of this field. The position taken up by the coil depends merely upon the phase of the current through the coil. If we assume uniformly revolving fields, and currents varying according to the sine law, the position will be such that at the instant the rotating field is parallel to the coil, the current in the latter is passing through its zero value. The angular deflection of the pointer from some fixed point on the scale measured in degrees, will be an exact measure of the phase of the current. If the currents are of irregular wave-form, and the rotating field is not uniform, this will not be precisely the case (see appendix), but there will in all cases be a fixed position of the coil for each phase, independent of the magnitudes of the currents in the different coils, and quite independent of the frequency, since this will affect currents and fields alike. The most efficient way of producing strong rotating fields is, of course, well known. It is exemplified in every induction motor. But it does not appear to have been noticed hitherto that phasemeters really act by means of rotating fields, and hence the means

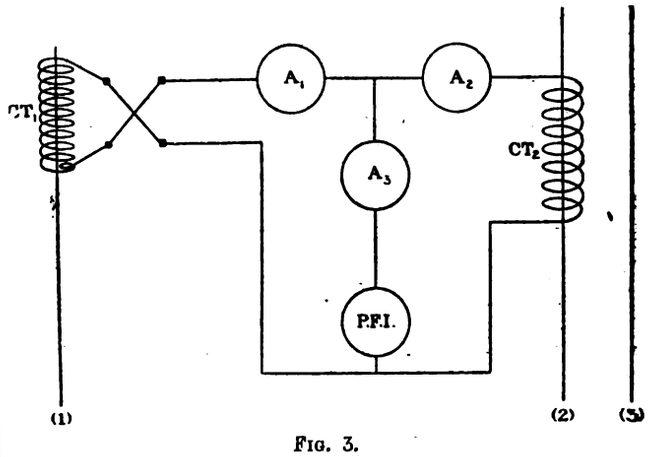

FIG. 3.

adopted in practice for producing such fields in commercial instruments are anything but the best available.

To illustrate this and other points I have had some instruments constructed in the technical school workshops, all designed for strong alternating magnetic fields. The first is the phasemeter illustrated in Fig. 2. The fixed coils are wound through circular ring stampings, just as in the stator of a three-phase motor. There are three coils, each of eight turns, wound with wire suitable for five or six amperes, with each coil brought to a separate pair of terminals. The portion corresponding with the rotor consists of a cylindrical block of circular stampings held in a fixed central position, and unwound. In the air-gap between the two is placed a pivoted coil similar to those used on moving-coil galvanometers, or voltmeters, but without control. It is capable of free motion about the axis of the instrument, and its position is indicated on the scale by an attached pointer. I have arranged some experiments which I think will convince you that this instrument is a very satisfactory indicator of phase or power factor. The position taken up by the pointer is quite definite under any given circumstances, and if the coil is moved out of its equilibrium position the forces tending to make it return are considerable, in spite of the fact that a very large non-inductive resistance is used in series with the pressure coil. This is only what is to be expected, since the strength of the field due to the fixed coils is about equal to that usual in permanent magnet direct-current instruments. Here, at all events, is one alternating-current instrument in which strong fields are employed without any of the disadvantages and errors supposed to be associated with the use of

Digitized by Google

iron under such circumstances. Of course it would be possible to wind the fixed coils for pressure instead of current, either for direct connection to the mains or, if necessary, for the secondary of a step-down transformer. In many cases the moving coil would be put in series with the secondary of a current transformer. It is usual now with high-tension mains to have two current transformers, each primary being placed in one of the mains, and each secondary circuit, after passing through an ammeter, returning through a path common to both secondary circuits, and in which an ammeter and power-factor indicator are placed. The connections are shown diagrammatically in Fig. 3, in which A_1, A_2 A_3 represent the ammeters, (1), (2), and (3) indicate the mains, in the first two of which the primaries of the current transformers, C T_1 and C T_2, are placed, and the power-factor indicator is represented by P F I. Owing to the vector properties of alternating currents, if the current transformers are alike, the current measured by the ammeter A_3 will indicate the current in the third main, as shown by the vector diagram in Fig. 4. With such an arrangement it would be advantageous to use a reversing switch (short-circuiting during reversal) on the secondary of one of the transformers, say C T_1, as indicated in Fig. 3. By reversing this switch A_2 is unaltered, A_1 becomes A^1, equal but opposite in phase to A_1, and A_3 becomes A_3', about 70 per cent. greater than A_3 in magnitude, and strictly in quadrature with it, whatever the wave-form may be, provided only A_1 and A_2 are equal in magnitude. These relations are shown in the vector diagram (Fig. 4), in which, owing

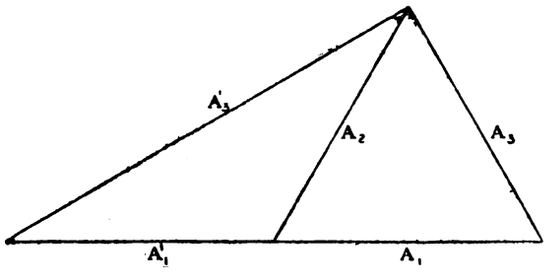

FIG. 4.

to the properties of a right-angled triangle A'_3 is perpendicular to A_3 if A_1, A_1', and A_2 are equal to each other, whatever may be the phase difference between A_1 and A_2 The advantage of this device arises from the fact that the power-factor indicator can be made to read on circuits of low power factor as well as on those of high power factor. As a rule, these instruments are calibrated between power factors 0·5 and 1·0, and are not available for low power-factor circuits. By using the reversing switch, the phase of the current passing through the instrument can be altered by 90 electrical degrees, so that the position corresponding with unity power factor is made to denote zero power factor, and by means of an additional calibration of the scale low power factors can be measured. If satisfactory power-factor indicators can be constructed, they will prove more serviceable than wattmeters on highly inductive circuits, since the latter instruments under such conditions are liable to large percentage errors, and their indications are low down on the scale.

(To be continued.)

PARLIAMENTARY POWERS.

The following additional applications for electric lighting provisional orders, tramway Bills, and other parliamentary powers are now being advertised in the *London Gazette* and elsewhere.

TRAMWAY AND LIGHT RAILWAY POWERS.

East Sussex Light Railway Company (extension of time); Bath Electric Tramways, Limited (light railways extension); Portmadoc, Beddgelert, and South Snowdon Railway Company (reconstruction and maintenance of light railways); Pudsey Corporation Tramways (construction of tramways); Bideford, Clovelly, and Hartland Light Railways (to incorporate a company); Colchester Corporation; Southampton Corporation; Tyneside Tramways and Tramroads Company; Leeds Corporation Tramways; Swansea Tramways Company; Hastings Tramways Company; Metropolitan Electric Tramways (Limited) Company (electrical powers); London Southern Tramways Company; Keighley Corporation Tramways; Tarporley and Mouldsworth Light Railways Company (construction of railway); Buenos Ayres Grand National Tramways Company, Limited (provisions as to amalgamation of company); Mexborough and Swinton Tramways Company (extension of time); Knutsford and Warrington Light Railway Company (construction and maintenance of light railways); Tanat Valley Light Railway Company (additional capital); Maidstone Corporation Light Railways (extensions); Coventry Electric Tramways Company (extension of time).

ELECTRIC LIGHTING ORDERS AND OTHER SUPPLY POWERS.

Central Electric Supply Company, Limited (supply to adjoining districts, etc., and erection of a generating station); Dover Corporation (electric lighting extension); Wimborne Urban District Council (electric lighting by the Metropolitan Electric Supply Company); Gravesend (electric lighting extensions to Northfleet); Shropshire and Worcestershire Electric Power Company (to extend the area of supply etc.); City of London Electric Lighting Company, Limited (extension of powers); Woolwich Borough Council (supply of electricity); Morley Corporation (further powers for supply of electricity); Marlborough (supply of electrical energy for all purposes within the borough and urban district by the Marlborough Electric Supply Company, Limited); Whitwood Urban District Council (electricity supply); Burslem Corporation (electric lighting extension); Southend-on-Sea Corporation (electricity supply extensions, etc.); Metropolitan Pneumatic Dispatch Company (construction, etc., of tubes, cables, and generation of electric power); Croydon Rural District Council (electric lighting); Ludlow Borough Council (storage and supply of electricity); Tewkesbury Borough Council (electric lighting); London County Council (supply of electrical fittings); Ware Urban District Council (electric lighting); Dorchester (electric lighting), by the Dorchester and District Electric Supply Company, Limited; Administrative County of London and District Electric Power Company (further powers); St. Albans Rural District Council (electric lighting); Whitworth Urban District Council (electric lighting); Durham (supply of electrical energy within the Rural District Council), by the Durham Electrical Power Distribution Company, Limited; North Metropolitan Electric Power Supply Company (powers to lay mains); East London and Lower Thames Electric Power Company (for the purpose of establishing electric works and supplying electric energy); Hemsworth Rural District Council (electric lighting); Portland Rural District Council (electricity supply); Brockenhurst and Milton (supply of electrical energy).

FORTHCOMING EVENTS.

FRIDAY, DEC. 2.

Junior Institution of Engineers.—At 8 p.m., "Some Points of Interest in the Construction of Torpedo-Boats," by Mr. H. E. Yarrow.

Institution of Civil Engineers (Students' Section).—At 8 p.m., "Midland Railway, West Riding Lines: The Construction of Contract No. 1," by Mr. R. T. McCallum.

SATURDAY, DEC. 3.

Institution of Junior Engineers.—Visit to the London Coliseum to inspect its features of engineering interest.

Institution of Electrical Engineers (Manchester Students' Section).—Visit to the Corporation sub-stations.

MONDAY, DEC. 5.

Society of Engineers.—"Condensing Plant," by Mr. W. E. Storey.

TUESDAY, DEC. 6.

Institution of Civil Engineers.—At 8 p.m., further discussion on Mr. J. F. C. Snell's paper, "Distribution of Electrical Energy"; "On the Construction of a Concrete Railway Viaduct," by Mr. A. Wood-Hill and Mr. E. D. Pain.

WEDNESDAY, DEC. 7.

Society of Arts.—At 8 p.m., "The International Exhibition at St. Louis, U.S.A.," by Mr. W. F. Reid

Institution of Electrical Engineers (Students' Section).—At 7.30 p.m., "The Gordon Electric Light Installation at Paddington, 1884-1904," by Mr. M. G. Tweedie.

THURSDAY, DEC. 8.

Society of Arts.—At 4.30 p.m., "Burma," by Sir Frederic W. R. Fryer, late Lieutenant-Governor of Burma.

Institution of Electrical Engineers.—At 8 p.m., "Hydrodynamical and Electromagnetic Investigations regarding the Magnetic-Flux Distribution in Toothed-Core Armatures," by Prof. H. S. Hele-Shaw, A. Hay, and P. H. Powell (conclusion of discussion); "Studies in Magnetic Testing," by Mr. G. F. C. Searle.

Institution of Electrical Engineers (Students' Section).—At 2 p.m., visit to the Robertson Electric Lamp Works, Brook Green, Hammersmith, W.

FRIDAY, DEC. 9.

Electro-Harmonic Society.—At 8 p.m., smoking concert.

SATURDAY, DEC. 10.

Junior Institution of Engineers.—At 3 p.m., visit to the International Gas Exhibition at Earl's Court.

Corps of Electrical Engineers (R.V.)—At 7.30 p.m., annual mess dinner at Anderton's Hotel.

Glasgow Technical College.—At 7.30 p.m., "Electro-Metallurgy—Some Notes on its Present Position," by Mr. J. D. Mackenzie.

THE METRIC FALLACY.

Quite recently we directed attention to the work of the British Weights and Measures Association, whose object is "the defence, standardising, and simplifying of British weights and measures." Within the past few days we have received from America a volume of some two hundred and thirty pages discussing the metric fallacy. The battle is joined. The mantle of the late Sir Frederick Bramwell has not been placed upon the shoulders of a successor. He laughed to scorn the attempts made to foist the metric system compulsorily upon this country, and he maintained that on the whole the existing system of British weights and measures was superior to the much-belauded metric system; but he understood that any innovation was likely to succeed, because innovators are talkative, energetic, and hang together, while defenders are inclined to pooh-pooh the dangers of the situation. We confess to cynicism, and the glamour of the arguments of a hundred and one professors and students do not outweigh the experience of a score of successful practical men. The aim of the professor is simplification of calculation of set hypothetical questions, the aim of the practical man is simplification of work, and getting of business. Text-book questions and examination questions are one thing, practical questions are quite different. Enthusiastic supporters of the metric system have tabulated the countries on the earth's surface that accept that system, and have left those who read or heard their words to infer that in these countries than the metric system there was none other. As a matter of fact, there is *no* country upon the face of the earth that has adopted the metric system for all, and probably not for the majority of purposes, where a system is required—not even France, the birthplace of the suggestion. The author of the "Metric Fallacy" has these very pertinent or impertinent remarks, according as the reader thinks for himself or follows his leader, on the subject. He says: "Should the reader be surprised at the facts regarding the limited use of the metric system herein given, he should remember that *no proof of anything to the contrary has ever been offered* (the italics are his). Whenever the metric advocates have learned that a government has passed a law favourable to the system, they have straightway conveniently assumed that it has become the common system in trade and commerce. They have not enquired into the working of these laws, nor into their scope or nature. Their logic has been: 'Such a country has passed a metric system law, therefore the people of the country have dropped their old units and taken up the new. Their stories of the imposing numbers of hundreds of millions of people who use the system have no other basis than this They have simply added the figures for the population of those countries which have passed some kind of a metric law, including those in which the laws are simply permissive and those in which the system has been adopted for government purposes alone. If the facts which are given in these pages turn the case to ridicule, they have nothing to thank but their own credulous willingness to believe anything favourable to their system, and to their free use of their own imagination without regard to facts." In this country we have been deafened with the cry, "We lose trade because we don't compulsorily accept the metric system." By trade is meant external trade. Surely America is competing for this same external trade, and this is what the American author says: "I shall show that our foreign customers do not care one picayune whether we adopt it or not, and I shall prove it by a flood of evidence." And by all that is true he does show it. He proves up to the hilt, to all unbiassed people, that the

Digitized by Google

statements usually made in regard to the metric system "have no foundation in fact, and no foundation of any kind except simple assumption combined with credulous willingness to believe anything whatever favourable to the system." He goes on to say, "With their system of weights and measures as a foundation, the English-speaking peoples have built up the greatest commercial and industrial structure the world has known. This system they are asked to abandon for the benefit of others at a cost that is beyond estimate, and for compensating advantages that to themselves are wholly trivial and imaginary." If these views of the American author—supported as they are by the new association at home we have referred to—are approximately correct, why is there an outcry for change? We believe it is really a psychological question. Once more the Latin races against the Anglo-Saxon; once more lightness, alertness, flexibility as against solidity and phlegmatism. The native Argentine or Chilian no more cared how his engine or railway gauge was measured than he cared for the man in the moon; but the metric supporter was there, and the system was adopted as any other system would have been adopted if put forward with the same *verve* and pertinacity. Where the Latin races have prevailed politically or otherwise we get the system, but of the forty-three countries which have in name accepted the system, none really uses it to the exclusion of all else—in fact, wherever you really examine a large part, if not the major part, of business is conducted on other systems, and the use of the metric system is largely confined to text-book literature and the hectoring lectures of the pure enthusiast. When a practical man adopts it, you may be sure that there are other underlying reasons for his course than general utility.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

HACKNEY AND THE ELECTRIC LIGHT.—MAXIMUM DEMAND SYSTEM OF CHARGING.

SIR,—A large number of ratepayers seem to experience some difficulty in finding out for themselves the average price which they will have to pay for electrical energy under the maximum demand system. The charges are as follows:

For Lighting.—For any quantity of electrical energy used each quarter not exceeding the equivalent of one hour's supply per day at the maximum demand, 7d. per unit; for any quantity used each quarter beyond, 1d. per unit.

For Power, Heating, and Cooking.—For any quantity of electrical energy used each quarter not exceeding the equivalent of one hour's supply per day at the maximum demand, 3d. per unit; for any quantity used each quarter beyond, 1d. per unit.

Under this scale the average rates for the different periods of use will be as follows:

TABLE OF AVERAGE PRICES.

Hours of use of maximum demand per day.	Average price per unit — For lighting.	For power.
1 hour	7·00d.	3·00d.
2 hours	4·00d.	2·00d.
3 ,,	3·00d.	1·67d.
4 ,,	2·50d.	1·50d.
5 ,,	2·20d.	1·40d.
6 ,,	2·00d.	1·33d.
7 ,,	1·85d.	1·29d.
8 ,,	1·75d.	1·25d.
9 ,,	1·67d.	1·22d.
10 ,,	1·60d.	1·20d.
24 ,,	1·25d.	1·08d.

The following is a simple method by which intending consumers or present consumers of electrical energy can ascertain for themselves what is likely to be the average price per unit which they will have to pay for their supply.

For Intending Consumers.—If you are using gas, light up the greatest number of burners you ever have in use at one time, and by the meter ascertain carefully how many cubic feet of gas are consumed per hour. Divide the year's consumption expressed in cubic feet by this figure and by 365. The result will be the average number of hours of use of the maximum demand per day throughout the year. Then refer to the foregoing table of average prices, and opposite the number of hours in the first column you will find in the second column the average rate per unit for electricity for lighting, and the average rate for power, etc., in the third column. For example: Suppose that (1) the consumption of gas with the greatest number of lamps ordinarily used, all alight is 50 cubic feet in one hour; (2) the year's consumption of gas is 54,750 cubic feet. Then, 54,750 cubic feet divided by 50 = 1,095 hours of use of maximum demand during the year. Dividing this figure by 365 days, that being the average daily use of the maximum demand = three hours. And for three hours, the table of prices shows that the average price for electricity for lighting is 3d. per unit, and for power, etc., 1·67d. per unit.

For Present Consumers.—Switch on the greatest number of lamps you require to use at any one time and by the meter ascertain carefully how many units are used in one hour. Divide the year's consumption in units by this figure and by 365. The result is the average number of hours' use of the maximum demand per day. Then refer to the table of average prices, and opposite the number of hours in the first column you will find in the second column the average rate per unit for electricity for lighting and the average rate for power in the third column. Expressed arithematically, the average number of hours' use per day of the maximum demand equals the consumption in units per annum, divided by the combined factors of the number of units used per hour when maximum number of lamps are in use and the number of days in the year. For example: Suppose that the (1) number of lamps switched on = 30 of 16 c.p.; (2) units used in one hour = two units; (3) year's consumption of electricity = 2,920 units; then 2,920 divided by 2 = 1,460, which divided by 365 = four hours, that being the average daily use of the maximum demand; and, for four hours, the table of prices shows that the average price of electricity is 2½d. per unit for lighting and 1½d. per unit for power. If the maximum number of lamps in use varies from quarter to quarter, treat each quarter separately, using in the equations figures of consumption per quarter and 91 in place of 365.—Yours, etc.,

L. L. ROBINSON, Borough Electrical Engineer, Hackney.

THE PATRIOTISM OF BRER FOX.

"De beastesses down yonder," said Uncle Remus, "was wantin' a lot er perwishuns, en dey asked Brer Tarrypin ter buy fer dem, fer ter see dat dey wasn't cheated. W'en Brer Tarrypin come fer ter look into de matter, he find dat de perwishuns bought befo' fum Brer Rabbit was better den de perwishuns bought fum Brer Wolf. So Brer Tarrypin he advertise in de papers fer perwishuns sold by Brer Rabbit, en den he sot down en waited fer de replies.

"Bimeby Brer Fox come smellin' 'roun' Brer Rabbit's chimbley-corner.

"'Who dar?' sez Brer Rabbit, sezee.

"'Fren',' sez Brer Fox.

"'How you find yo'se'f deze days, Brer Fox?' sez Brer Rabbit, sezee.

"'Lounjun 'roun' en suffer'n,' sez Brer Fox, sezee.

"'W'at ail you, Brer Fox?' sez Brer Rabbit, sezee.

"'Lor'! Brer Rabbit, you dunner w'at trouble is,' sez Brer Fox, sezee. 'I wanter put in fer de perwishuns, en Brer Tarrypin sez I've got ter buy fum you,' sez Brer Fox, sezee.

"Now Brer Rabbit knew dat Brer Fox was mighty familious wid Brer Wolf en always bought fum him, so he lit a seegar and sez: 'I'm oblije' ter you, Brer Fox, fer de compliment, en I sympafise wid you. You look berry bad,' sez Brer Rabbit, sezee, 'en I should advise you fer ter go home en take ter yo' bed.'

Digitized by Google

"'It aint so bad as dat,' say Brer Fox, sezee, 'but I s'pose I must buy yo' stuff.'

"'You needn't 'less you wanter,' sez Brer Rabbit, sezee.

"'I'll tell you w'at, Brer Rabbit,' sez Brer Fox, sezee. 'I know dat yo' perwishuns come fum Germany, but if yo'll gib me pref'renshul terms I'll buy fum you. But if you ain't gwineter, I'll go ter Brer Wolf.'

"Den Brer Rabbit up en tell Brer Fox how 'twuz, en he 'low'd, Brer Rabbit did, dat Brer Fox was de lowdownest w'atsizname w'at he ever run up wid. En Brer Rabbit tol' Brer Fox ter go ter his fren' Brer Wolf, en den he showed Brer Fox outer de front-po'ch.

"W'en Brer Fox got some way off he holler out: 'Brer Rabbit, yer'll hear er diz bizness befo' you've done, en I'll tell all de udder animils.'

"But Brer Rabbit he lay low. Den Brer Fox he went ter Brer Wolf en he sez, sezee: 'Brer Wolf, yer perwishuns ain't unlike Brer Rabbit's, en fer ol' fren'ship's sake I'll buy fum you dis once if yo'll gib me de ushul pref'renshul terms.'

"Brer Wolf 'low'd he do anythin' fer ter settle Brer Rabbit's hash, en Brer Fox think ter hisse'f dis looks mighty nice game. So den he lope off home, en he rubbed his han's thinkin' er how Brer Rabbit ud feel sick

"En Brer Rabbit he lay low. W'en de beastesses en Brer Tarrypin examine de offers, dey gave de order fer Mr. Tukkey Buzzard 'cose he'd give dem w'at dey ask for; en Brer Fox he done got nuffin 'cose he give dem w'at dey didn't want.

"W'en Brer Fox heerd er dat he kick up a monstus racket, en he fa'rly to' up de groun', he did, en he jump so high en so quick dat he mighty nigh snatch his own tail off. Den he tied a wet han'kerchief roun' his head, en thought fer two days. En bimeby he wrote ter de papers, en he sez, sezee: 'De action er de beastesses is impatriotic,' sezee. 'Dey give de order ter Mr. Tukkey Buzzard fer German perwishuns, en here am I tryin' fer ter improve de trade er de country,' sezee, 'en sacrificin' part er me profit. I call der doin's monstus bad, w'en me en de udder animils is payin' rates,' sezee, 'fer ter keep sech pesterin' people es Brer Rabbit outer de country. I sign mese'f "Patriotic Fox," sez Brer Fox, sezee.'

"Is that all?" asked the little boy.

"Well, no," replied Uncle Remus, "de udder animils thought Brer Fox was patriotic en mighty badly treated, but yo' see, sonny, dat his patriotism was jest worth de pref'renshul terms he got fum Brer Wolf."

[This correspondence seems to have gone far enough. Everyone has had his say, and except that the muddle of (1) architect specifying, (2) admitting that alternative tenders should not be out of court, (3) guardians accepting without examination of tenders by architect, be cleared up, the whole transaction remains in the category of peculiar methods of local dealing with professional men and tenders. ED., *E. E.*]

APPOINTMENTS VACANT.

Pupil in company's light and power station. See advertisement in last issue.

Senior Operator, Glasgow Telephone Department. Applications by Dec. 5. See advertisement iu last issue.

Engineering Apprentice, Gilbert Little and Sons, Limited, Smethwick. See advertisement in last issue.

Draughtsman, Electrical Department of the Admiralty. Applications by Dec. 5. See advertisement in last issue.

Switchboard Electrician, Glasgow Telephone Department. Applications by Dec. 5. See advertisement in last issue.

Tramways Manager, Newcastle Corporation. Proposed salary to commence at £700 per annum, and to be raised by £50 the following year, ultimately to reach £800.

Draughtsman (temporary), Swindon Corporation. Wages, 30s. per week. See advertisement.

Tramway Extension.—To-morrow (Saturday) the Metropolitan Electric Tramways, Limited, will open for public traffic another extension of their electric tramways. The new line, which is about five miles long and has double track throughout, runs from Cricklewood to Edgware. The electricity for working this line will be supplied from the large generating station of the North Metropolitan Electric Power Supply Company at Willesden.

THE CABLE ESTIMATING CLERK'S COMPLAINT.

A DIRGE IN ONE SPASM BUT MANY METRES.

Prologue.

Our lot is not a happy one;
Few are the days of bliss—
But nights of woe, till tenders go
We hardly ever miss.
When after full eight hours of work,
At half-past five or so,
Thinking of home and cheerful tome,
We slowly rise to go—
Alas! the evening's post brings in
A letter, short and clear;
From someone who, by all that's blue,
Has signed himself, with cheerful vim,
"Consulting Engineer."

Heaven bless the man, whose letter ran:
"Please work me out at once,
Five lighting schemes, in detail priced,
From the enclosèd plan.
The first for mains run overhead
On wooden poles stuck up in holes.
The second scheme aloft as well,
But poles of steel like Spencer's sell.
The third for cable armoured laid in earth.
The fourth a solid system: this I've heard
Is very good with troughs of wood,
For which I'd take your word.
The fifth for cables, covered o'er with lead
Drawn into conduits on a concrete bed.
And p'rhaps you also wouldn't mind
Quoting for various insulations,
Paper, rubber—any other kind
Used with electric lighting stations.
And if you wish for business with your firm,
Be sure your offers reach me by return."

And that is all from this dear man:
So after making a few choice remarks
And ordering in our tea and bed,
We ope the plan, and this we scan
To get some sort of information.
This plan, in size, I should surmise,
Is rather larger than a postage stamp—
No name of town, which you will own
Is rather vague; it may be Hague
Or Cairo, Chowbent or Boulogne;
Fez, Philippi, or Featherstone:
No streets are named, no scale is given:
It may be earth, it may be heaven;
The scale may be sixteen to seven,
Or ten to fifteen bar eleven:
One inch to mile, one mile to inch,
Perchance we'd guess it at a pinch.

We hate to be beaten by trifles like these,
We try every way up till our brain 'gins to freeze—
We *might* even guess the maximum load—
Or the streets where the "leets"
Will be wanted—or even the road
Where the station will stand;
Perhaps *there* near the river, or on this waste land,
Or anywhere, nowhere—O! let it be d——d.

So, being but mortal, we trot home to bed,
And next day to this man who is thick in the head
We write a nice letter of thanks for his plan,
And if he'll send on a few details omitted
We'll send in our tenders as quick as we can,
And do all his work with the greatest of pleasure;
In fact, it's a privilege and joy beyond measure.
And so on, and so on, etcetera, *ad lib.*—
(Let us hope we shall be forgiven the fib.)

* * * * *

HYDRODYNAMICAL AND ELECTROMAGNETIC INVESTIGATIONS REGARDING THE MAGNETIC-FLUX DISTRIBUTION IN TOOTHED-CORE ARMATURES.*

BY PROF. H. S. HELE-SHAW, F.R.S., LL.D., ALFRED HAY, D.SC., AND P. H. POWELL, M.SC., M ENG

(*Concluded from page 792.*)

RESULTS OF BALLISTIC EXPERIMENTS.

The magnetic flux through the top, the middle, and the bottom of the tooth was determined for five different values

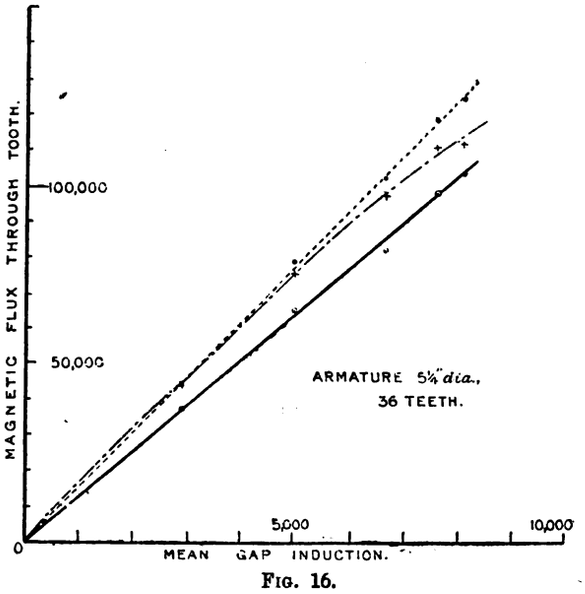

FIG. 16.

of the mean gap induction, ranging from about 3,000 to about 9,000 C.G.S. lines per square centimetre, for each of the five armature cores experimented upon. The results obtained are given in Table III., and are graphically exhibited in Figs. 16-20, the curves there shown having the mean gap induction for abscissæ and the magnetic fluxes through the various cross-sections of the tooth for ordinates. The full-line curve in each case refers to the total flux through the top of the tooth, the dotted curve to the flux

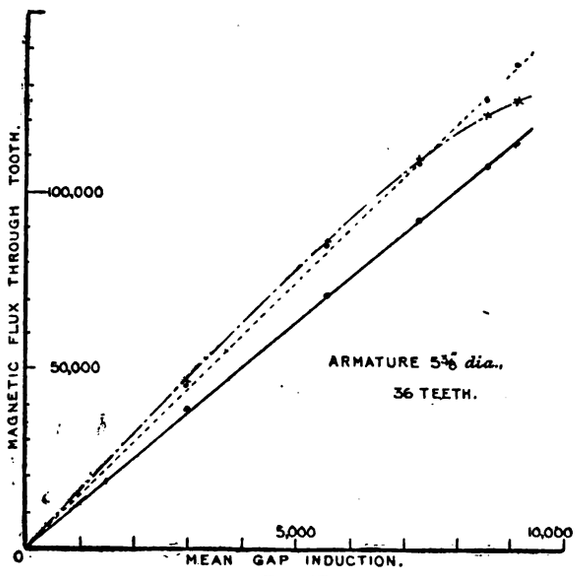

FIG. 17.

through the middle of the tooth, and the chain-dotted curve to the flux through the base of the tooth. The three readings marked with an asterisk in Table III. are open to some doubt, and are almost certainly too low; unfortunately, the core had been dismantled before the discrepancy was noticed, and the readings could not be repeated. A glance at the stream-line diagrams shows that the total flux through a cross-section of the tooth some distance below the surface of the armature is considerably greater than the flux through the top of the tooth. This is fully borne out by the ballistic measurements, which show clearly the steady increase in the magnetic flux as we proceed down

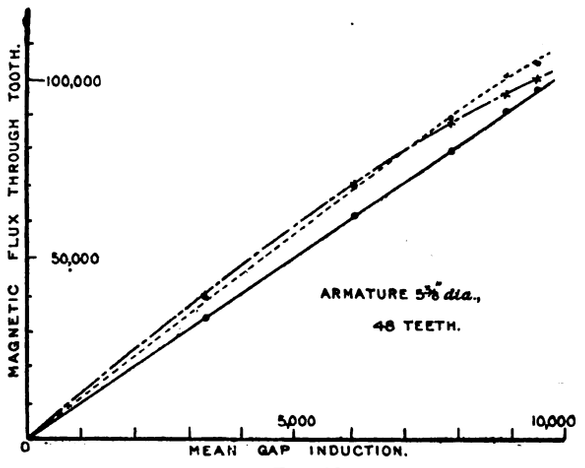

FIG. 18.

the tooth—so long, at any rate, as the induction at the base of the tooth does not exceed about 20,000. When the induction is pushed beyond this limit, another effect, not indicated by the stream-line diagrams (in which the permeability is constant), comes into play. The flux, after reaching a maximum value at a certain depth, begins to decrease, lines of induction leaving the flank of the tooth and crowding into the slot. This effect is very strongly

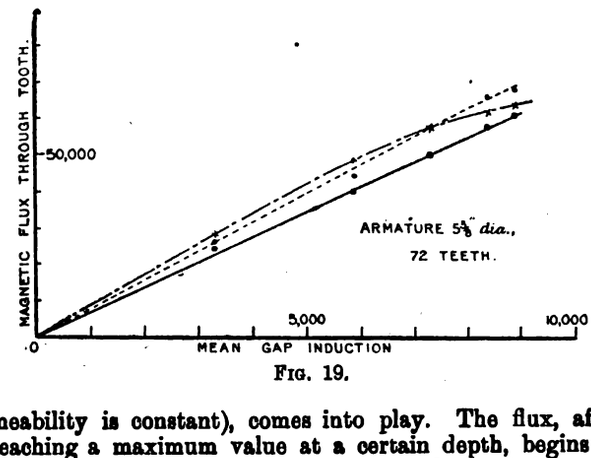

FIG. 19.

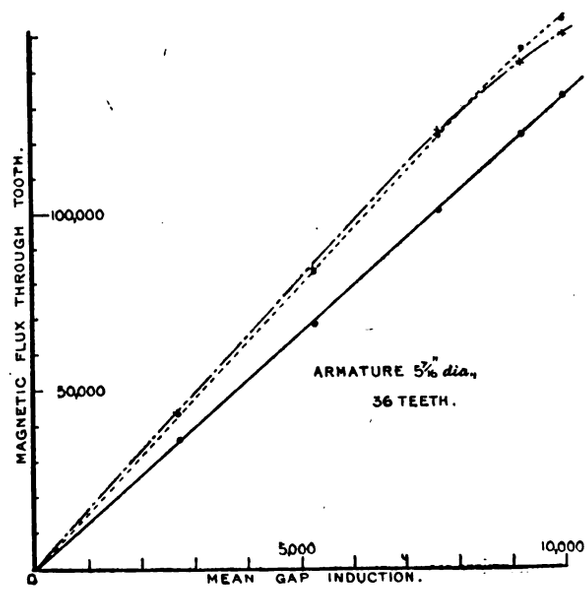

FIG. 20.

marked for all the higher values of the gap induction, and is indicated by the crossing of the curves in Figs. 16-20.

So long as the air-gap remains of constant length, and the ratio of width of slot to width of tooth is not materially altered, no appreciable change in the flux distribution along

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

a tooth is produced by varying the number of teeth—*i.e.*, the width of tooth. If, however, the air-gap is steadily increased, then, as an examination of Figs. 16-20 shows, the depth at which, for a given gap induction, the flux reaches a maximum value increases with increase of air-gap.

TABLE III.

—	Mean gap induction	Total magnetic flux. Top of tooth.	Middle of tooth.	Base of tooth	Magnetic induction Top of tooth	Middle of tooth	Base of tooth
Armature 5½in. in diameter, 36 teeth.	2,890	37 000	44,400	*43,800	4,790	7,040	8 570

	8,880	91,000	101,900	96,200	14,700	19 400	21,100
	9,440	97,500	105,400	101,000	15,700	20,000	22,140
Armature 5⅝in. in diameter, 72 teeth.	3,280	24,300	26,800	28 600	6,070	8 130	10,560
	5 810	40,300	44,900	46,000	10,080	13 600	17,000
	7,270	50,900	57,800	57,300	12,700	17,500	21,160
	8,380	58,400	66,200	62,300	14,600	20 100	23,000
	8,870	61,300	68,900	64,400	15,300	20,900	23,800
Armature 5⅞in. in diameter, 36 teeth.	2,680	36 100	43,400	43,500	4,280	6,020	7,450
	5,260	68,400	83,100	83,700	8,100	11,540	14,350
	7,630	100,700	122,000	122,700	11,900	16 950	21,000
	9 200	122,400	145,800	142,200	14 500	20,200	24,400
	10,000	133,300	154,100	150,200	15,800	21,400	25,700

For the range of gap induction used, the curves connecting the total flux through the top and middle cross-sections of the tooth with the mean air-gap induction are almost indistinguishable from straight lines, which necessarily pass through the origin. Such, however, is no longer the case for the curves relating to the base of the tooth, the initial portion only of which is straight. It is, of course, obvious that if it had been possible to push the induction far enough, the curves for the top and middle of the tooth would have commenced bending towards the horizontal axis in a manner similar to that of the curve for the base of the tooth—in fact, this tendency is clearly marked in the case of the dotted curves of Figs. 18 and 20.

CONCLUSION.

The experiments described in the present paper occupied the greater part of two years, and the expense of constructing the apparatus and photographing the stream-line slides was defrayed out of a research grant made by the Royal Society. We are indebted to Prof. E. W. Marchant, D.Sc., and several of his students for valuable assistance in connection with the somewhat laborious experiments which form the subject of our paper.

FROM AMSTERDAM TO ZANDVOORT BY LIGHT RAILWAY.

We have great pleasure in recording the successful completion by Messrs. J. G. White and Co., Limited, of a system of light railways between Amsterdam and Haarlem. Apart from the engineering difficulties which have attended the construction of this line, due to the treacherous nature of Holland's sandy soil, in conjunction with the Government's requirements as to the level of the track, the undertaking presents some interesting features. Altogether unusual facilities have, for instance, been provided by the Amsterdam municipality to enable the light railway company's cars to run right into the centre of the town. It was not a question of through running in the ordinary sense, because the gauge of the Corporation tramways differs from that adopted by the company, thus making a simple physical junction between the two systems impossible. The obvious way out of the difficulty was to lay a third rail over a section of the tramway track in Amsterdam, and this work was undertaken by the Corporation contemporaneously with the conversion of their whole system for electric traction. Outside Amsterdam the company's lines leave the public highway and proceed across sparsely-populated country to Haarlem, where a junction is made with the single-track light railway to Zandvoort, belonging to an associated company. Thus the residents of Amsterdam are placed within direct reach of a charming health resort on the open coast, about 17 miles distant. The success of the enterprise depends almost entirely upon the development of a large summer traffic. Assuming the average Dutchman to be as fond of a glimpse of the open sea as the average Englishman, there can be little doubt about this development. Even if a Dutchman's instinct does not turn him seaward, the reputed objectionable state of the Amsterdam canals during hot weather should certainly drive him. Perhaps a little judicious stirring of these canals might serve to stimulate a desire for fresh air when receipts are unsatisfactory. But apart from an estimate of returns on this basis, the undertaking has many points in its favour. First and foremost, it is a light railway in the fullest sense of the term—that is to say, it enjoys for the most part an exclusive right of way, thus making the maintenance of a high average speed not only legal but possible. Moreover, the track possesses very few curves, and is absolutely level throughout. We are indebted to Messrs. J. G. White and Co., Limited, for an opportunity to inspect the undertaking last week, when every facility was given us to see exactly how the work has been carried out. Here, it may be mentioned that the firm in question have been connected with the scheme as contractors and engineers for the whole. In regard to the generating plant installed, the best features of English practice have been introduced, notably in the case of the main engines, which are of the high-speed type by Belliss and Morcom. At the same time, the general design does not suggest an English scheme transferred to Holland. On the contrary, there is evidence of extreme care having been taken to adapt the scheme to local conditions, especially in regard to the track work and rolling-stock. We do not remember having ever travelled with greater comfort than on this railway, which fact speaks well for the capability of an English firm to do good work when given a free hand in a foreign country, especially as in this case the difficulties involved were exceptional.

Bearing in mind experience nearer home, our readers will not be surprised to learn that this promising undertaking is due to American enterprise, Messrs. J. G. White having acted as agents for an American syndicate in selecting the field for the venture. In addition to the land required for the permanent way, the company have acquired large tracts of adjoining country with a view to leasing the same in plots for building purposes as Amsterdam extends. So far as the capital invested is concerned, only the debenture stock is held in Holland.

In a subsequent issue we hope to give a full illustrated description of the undertaking, together with our impressions of some of the more interesting engineering features.

We may add here that, apart from its main object, our recent visit to Amsterdam will long remain to us as a pleasant episode—thanks chiefly to Mr. A. N. Connett and Mr. Murphy, of Messrs. J. G. White and Co., whose care for our creature comforts was unflagging. To these gentlemen we are greatly indebted for an instructive and, at the same time, extremely pleasant trip.

PERSONAL.

Mr. H. A Fleet has been appointed station superintendent to the Yorkshire Electric Power Company, and has resigned the corresponding position held by him at the power station of the Mersey Railway Company.

We understand that Mr. Harris, assistant engineer to the Edinburgh and District Tramways Company, Limited, has succeeded Mr. Colam as principal engineer.

Mr. J. R. W. Grainge, shift engineer at Battersea, has resigned.

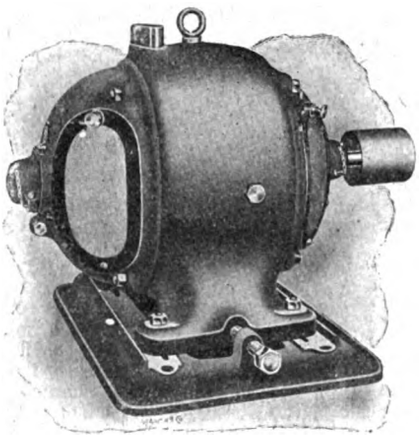
TRADE NOTICES AND NOVELTIES.

R. E. Type Motors.

The Rhodes Electrical Manufacturing Company, Limited, of 70 and 71, Bishopsgate-street Within, London, E.C., and Bradford, have just issued a new list of their R. E. type continuous-current motors, giving particulars of the output of the machines at different speeds, together with prices and approximate shipping measurements in a form convenient for reference.



These motors are made in standard sizes, ranging from ½ h.p. to 60 h.p., each size being listed for two voltages—namely, 230 volts and 460 volts. The accompanying illustration shows the general design of an R. E. type motor, fitted with new pattern end shields and perforated enclosing covers.

"Ediswan" Novelties.

The accompanying illustration (Fig. 1) shows a high-voltage switch plug, specially designed and introduced by the Edison and Swan United Electric Light Company, Limited, Queen-street, London, E.C., to meet the demand for a switch-controlled wall socket involving only one operation. This switch

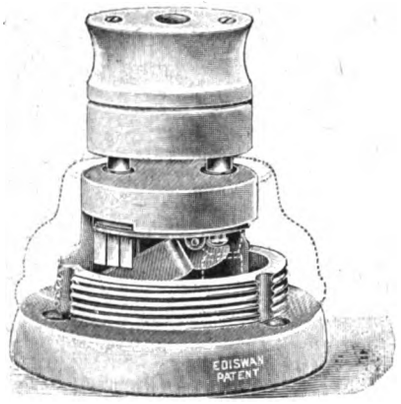


FIG. 1.—"Ediswan" H.V. Switch Plug.

plug consists essentially of a quick-break, double-contact switch, which is closed by the insertion of and opened by the withdrawal of the plug. The latter is made with a special shaped prong, which pushes over a cam on the switch spindle when

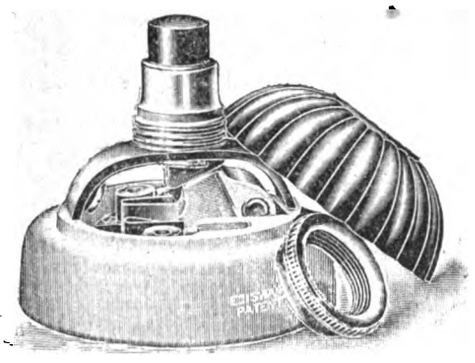

FIG. 2. "Ediswan" Button Switch.

making the circuit, and engages a detent on this cam when breaking the circuit, the action being entirely automatic. The circuit is only made when the plug is right home, hence there can be no live contacts on the socket.

Fig. 2 illustrates the "Ediswan" "button" switch, which marks a new departure in point switches. Hitherto the only switches working on this principle have required two separate pushes, one for closing and the other for opening the circuit. With the "button" switch, however, the cycle of operations is effected by means of a single push. Besides having all the good features of the well-known "wedge" tumbler switch, the movement of which it retains, the "button" switch, it is claimed, possesses the following among other additional advantages: independent break, freedom from liability to arc, better insulation of the operator from shock, and neater appearance, especially in regard to the patterns supplied for flush work.

Nernst Lamps.

The latest pamphlet issued by the Electrical Company, Limited, 121-125, Charing Cross-road, W.C., contains some interesting views of Nernst lamps installed by them in the Edinburgh Museum, Houses of Parliament, restaurants, railway stations, etc. In one very large establishment, we understand, no less than 10,000 of these lamps are in use. The latter portion of the pamphlet deals more particularly with the use of the lamps for street-lighting, views of the installations in Barnes, Maidstone, and Gravesend being given; while the last two pages are devoted to the Express and Multiple types, both of which have been illustrated in these columns.

Catalogues, etc., Received.

THE ELECTRICAL COMPANY, LIMITED, 121-125, Charing Cross-road, W.C.—Leaflet No. 99: cut-outs for high voltage, illustrated. Leaflet No. 100: casing and capping, illustrated. Leaflet No. 109: lampholders for Nernst lamps, illustrated.

POPLAR ELECTRICITY ACCOUNTS.

From the accounts of the Poplar electricity department for the year ended March 31, 1904, it appears that the total expenditure on capital account to that date amounted to £194,300, of which £2,493 had been repaid. We give herewith abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Generation of electricity	8,119	17	8
Distribution of electricity	980	6	11
Attending and repairs to public lamps	2,079	17	7

PHYSICAL SOCIETY.

At the meeting of the above society on Nov. 11, Dr. R. T. Glazebrooke, F.R.S., president, in the chair,

A paper on the "**Investigation of the Variations of Magnetic Hysteresis with Frequency,**" by **Prof. T. R. Lyle**, was read by Prof. Trouton. The experiments were made on two rings of laminated annealed iron, in one of which the radial breadth of the iron was considerable relative to its mean radius. These rings were magnetised by alternating currents of different strengths and periods. Both the magnetising-current wave and the magnetic-flux wave were quantitatively determined by a wave-tracer (described by the author in the *Phil. Mag.*, November, 1903), and the wave-forms so obtained subjected to harmonic analysis. The experiments were divided into series, in which the period and wave-form of the magnetising current were kept as nearly constant as possible throughout any one series, while its strength was varied. The analytic expressions for the associated current and flux waves for a few series are given in tabular form. From the analytic expressions for each pair of associated waves it was found that when the magnetising current was approximately sinusoidal, the total iron loss (I) was, within certain limits of the induction, given by a formula $I=(a+bn)B^{1\cdot67}$, where n is the number of periods per second, B the "effective induction," and a and b are constants. When from the total iron loss per cubic centimetre per cycle the sum of the statical hysteresis and the value that theory assigns to eddy-current loss was subtracted, a considerable quantity remained, which increased both when the frequency and the flux density increased. This quantity, called by Fleming the kinetic hysteresis, has been obtained for each experiment. An interesting case of transformation, and what is called refluxion of energy, is drawn attention to and discussed. If the E.M.F. impressed on the magnetising circuit on the iron ring be sinusoidal, the flux wave produced contains third, fifth, etc., harmonics. These higher flux harmonics induce currents in the magnetising circuit which are dissipated as heat in it. Thus we have a transformation of electrical energy due to alternating currents of frequency n to energy of currents whose frequencies are $3n$, $5n$, etc., which is reflected back into the magnetising circuit. This the author believes is a hitherto unnoticed source of transformer loss.

Dr. J. A. Fleming said the paper appeared to contain many points of interest. The result given by the author that the total iron losses varied as the 1·57 power of the induction density, agreed with practice. There was, however, no hard-and-fast law for the calculation of the iron losses, but the number 1·6 was useful as a guide. In many cases the loss varied according to an exponent considerably less than 1·6. He pointed out that this exponent was practically the same for all magnetic metals, and said it would be interesting to know if the law would be true in the case of a Ewing model of a magnet. The paper clearly showed that transformer losses should be determined by measuring the watts. The experimental determination of the statical hysteresis was not of practical importance; what was wanted was the real loss which varied with the frequency. We should be able to calculate the loss at any induction and frequency from the known loss at any particular induction and frequency.

Mr. A. Campbell drew attention to the work of an earlier investigator on the same subject. Max Wien, in a paper on "Magnetisation by Alternating Currents" (*Wied. Ann.* (13), August, 1898), gives results of an investigation on the change in flux density and hysteresis loss due to variation in frequency of the magnetising alternating current. His chief method of measurement was based on Maxwell's method of comparing two self-inductances. One of the inductive coils so compared was the winding of the iron ring under test, the source of voltage being alternating (128 to 520 ⁓ per second), and the indicating instrument a tuned optical telephone or vibration galvanometer. The bridge measurements (starting with direct current) gave the "effective" resistance and self-inductance of the ring winding, and from these (with the dimensions, etc.) were deduced the values of B and the hysteresis loss due to the fundamental component of the alternating flux, allowance for eddy currents having been made. A number of conclusions are drawn from the results; amongst others, that increase of frequency decreases B for a given value of H, and increases the hysteresis loss for a given value of B. This appears to indicate that with quickly alternating fields B lags behind H. It is interesting to notice that for one of the rings tested the "kinetic hysteresis" found for $n = 128$ is of somewhat the same order of magnitude as that given by the rings of Prof. Lyle at lower frequencies.

Dr. D. K. Morris, in a letter to the secretary, said that much experimental work on the subject of the paper had been recently carried out, chiefly by Mr. R. P. Hulse, in the University of Birmingham; and it always appeared that with good transformer iron, the increase of hysteresis with frequency was *less* than that found by Prof. Lyle. These experiments were made with ring magnets built up of stampings, properly insulated from one another, and having a small difference only between internal and external radius. Another method of experimenting was the following: If the no-load loss of a transformer be measured at different frequencies, the voltage being so adjusted as to give constant flux density, then by dividing each measurement by the frequency and plotting the quotients against the frequency, a straight line is obtained from whose inclination the eddy-current constant can be obtained, on the assumption that hysteresis does not vary with the frequency. The author quotes $\frac{\pi^2}{6}=1\cdot645$ as this constant (that figure, namely, which when multiplied by the [thickness of stamping]^2, by the [induction density]^2 and the [frequency]^2, and divided by the specific resistance of the stampings, will give the eddy-current loss). Different methods of arriving at it as previously given, show that it certainly lies between 1·2 and 2·0. Measurements on transformers by the above method give figures between 4 and 5 as far as Dr. Morris's experience goes. It would be interesting to know if any other Fellow had made similar measurements. This means that that portion of the loss which does not simply increase proportionally with the frequency is more than double that which is ordinarily explained by eddy currents. Such measurements have been made for a maximum flux density from B = 2,600 to B = 5,000 lines per square centimetre, and the results are in close agreement with those of Prof. Lyle. Dr. Morris has usually attributed the excess eddy-current loss to current flowing from plate to plate. Such currents certainly did not occur in the author's experiments. Sometimes the discrepancy between observed and calculated eddy currents is due in part to the existence of higher harmonics in the flux wave for which the relatively large allowance has not been made. But if it is not due to either of these causes, it certainly would seem to indicate "kinetic hysteresis." Prof. Lyle asserts that "if the E.M.F. wave impressed on the magnetising winding is sinusoidal, the flux wave will contain third harmonics," etc. It is quite true that the magnetising *current* contains such harmonics, but unless the resistance of the magnetising winding is very high, these harmonics will not appear appreciably either in the back voltage or the corresponding flux. The practical significance of the "reflected energy" referred to is, therefore, very slight.

Mr. T. H. Blakesley said that 10 or 12 years ago he read a paper before the society describing experiments which pointed to the existence of kinetic hysteresis. The present paper substantiated what he said then.

A paper "**On the Practical Determination of the Mean Spherical Candle-Power of Incandescent and Arc Lamps,**" by **Mr. G. B. Dyke**, was read by the author. Mr. Dyke points out the need of an improved method of expressing the efficiency of incandescent lamps, and adopts the suggestion of Dr. Fleming of expressing the whole flux of light in lumens per watt. The expression of the efficiency in this manner involves the determination of the mean spherical candle-power (M.S.C.P.), and the paper describes a method of doing this. The objects of the paper are (1) to obtain curves showing the variations of candle-power of incandescent lamps in a horizontal plane; (2) to obtain reduction factors by which the mean horizontal candle-power (M.H.C.P.) may be calculated from the maximum horizontal candle-power (C.P.); and (3) to obtain reduction factors for deducing the M.S.C.P. from the M.H.C.P. and from the C.P. A self-contained motor-driven lampholder is described which rotates the lamp about a vertical axis at from 230 to 300 revolutions per minute. The M.H.C.P. was determined by spinning the lamps, and by taking C.P.S in different azimuths by a step-to-step method. The results agreed within the limits of experimental error, thus showing that the filaments were not sensibly distorted during rotation. An integrating photometer was used to determine the ratio (M.S.C.P.)/(M.H.C.P.). The instrument is of the type suggested by Mr. C. P. Matthews, and consists of several pairs of mirrors placed around the circumference of a semicircle, and so arranged that light emitted from a source placed at the centre of the system is incident upon the photometer screen, also situate at the centre, at the same angle with the vertical as it made on emission from the centre. It is shown how the ratio (M.S.C.P.)/(M.H C.P.) can be determined by observing one distance after obtaining a photometric balance. The effects of any departure from Lambert's cosine law, and of varying reflection coefficients of the mirrors, were investigated and allowed for. It was also found impossible to reduce the size of the apparatus by interposing ground-glass screens because of the varying absorption of ground glass for light of different colours. Nine types of incandescent lamp were experimented upon, and the high peaks and depressions on the curves of horizontal intensity were ascribed respectively to a mirror action of the bulb and to portions of the filaments obstructing the light from other portions. Values of the ratios (M.H.C.P.)/(C.P.), (M.S.C.P.)/(C.P.), and (M.S.C.P.)/(M.H.C.P.) have been obtained, and for lamps of the same type of filament it is found that the ratio (M.S.C.P.)/(M.H.C.P.) is remarkably constant. The author therefore suggests the determination of the M.H.C.P. by means of a rotator, and then, with the aid of a reduction factor, determined once and for all for a particular type of filament by an integrating photometer, the deduction of the M.S.C.P. Preliminary experiments upon arc lamps seem to show that a similar method may be adopted for the determination of their M.S.C.P.

Dr. J. A. Fleming congratulated the author, and referred to the peculiar difficulties under which the research had been conducted at University College. Two features of the integrating photometer used were the possibility of compensating departures from the cosine law by the setting of the mirrors and the determination of the M.S.C.P. from one reading. It was now as easy to obtain a value for the M.S.C.P. as to obtain a useless measure of the horizontal intensity in any particular direction. The variation in the reflecting powers of the mirrors due to dust and dirt could also be eliminated.

Mr. Patterson gave an account of similar experiments which were being carried out at the National Physical Laboratory. Referring to the fact that the author had taken for his zero position in determining the ordinary C.P. of a lamp that in which the mean plane of the filament was at right angles to the axis of the photometric bench, he pointed out that this position was unsatisfactory because of the prevalence of streaks and shadows on the screen. The M.H.C.P., and not the C.P. in any particular direction, was the only unit now in use. The results of the author were in close agreement with those obtained at the National Physical Laboratory.

Mr. W. Duddell pointed out that if the peaks in the curves of horizontal intensity were due to reflection from the bulb, one would expect that their position would vary with the distance between the lamp and screen. He asked the author if he had noticed any such variation. The integrating photometer described in the paper was very cumbersome, and he would like to know in what respects it was superior to Blondel's lumenmeter.

Dr. C. Chree remarked that it would be interesting mathematically to express the illumination in a series of spherical harmonics.

Digitized by Google

The **Chairman** expressed his interest in the fact that some of the results of the author had been confirmed by Mr. Patterson at the National Physical Laboratory. He had recently been in America, and found that the integrating photometer was in use for measurements upon arc lamps, but that incandescent lamps were measured with a rotator, no particular regard being paid to the M.S.C.P. With regard to the observations of Dr. Chree, he said that Mr. Patterson could give him sufficient data to carry out the calculations.

The **Author**, in reply to Mr. Duddell, said that although he had not varied the distance between the lamp and the screen, he had taken photographs of the "blaze" of the lamp at different distances, and found that it was always the same.

Exhibition of Apparatus by **Mr. R. W. Paul.**—The construction of highly sensitive pivoted electrical instruments has been rendered difficult by the fact that delicate pivots will not admit of transporting without injury. A number of galvanometers were shown in which the design was based upon the use of a moving coil, supported on one pivot in a powerful and uniform magnetic field, and controlled by a spring. The adoption of one, in place of the usual two pivots, renders it feasible to raise the coil when the instrument is out of use, and thus secure the pivot from risk of injury. By taking advantage of this, and the incidental reduction of pivot friction, a practical instrument has been made approaching in sensibility to that of a reflecting galvanometer. Some of the instruments exhibited gave a full scale reading of 100 divisions for two millivolts or for 60 microamperes. Combined with shunts and resistances other forms gave direct reading insulation measurements to 2,500 megohms, pressures to 500 volts, and currents to 25 milliamperes in the one apparatus. Demonstrations were given of the suitability of the galvanometers for pyrometer use. The galvanometers are so designed that accurate levelling is unnecessary. A simple, non-reflecting, suspended-coil galvanometer for the student's use, with a sensibility of one division per microampere, was also exhibited. A new design of lantern, adapted for science lectures, and for use with three Nernst filaments arranged closely together, was shown in action. It is capable of being instantly changed from horizontal to vertical projection, can be fitted with a reversing prism, and has a wide adjustment for focussing. Another exhibit was an Ayrton-Mather reflecting electrostatic voltmeter with a magnetic damping device. The instrument shown had a sensibility of 500mm. at 1m. for 30 volts, but similar instruments are made to give this deflection with pressures as low as eight volts.

At the meeting on Nov. 25, Dr. R. T. Glazebrooke, F.R.S., president, in the chair,

A paper on **"The Measurement of Small Differences of Phase"** was read by **Dr. W. E. Sumpner.** Hitherto, in order to measure the differences of phase between alternating-current quantities, it has been necessary to use some method involving the simultaneous reading of three deflectional instruments, such as the wattmeter method, or the three-voltmeter method either in its original or in some modified form. These methods cannot be successfully applied when the phase differences to be determined are small. The author describes new voltmeter methods which may be used for the purpose, and gives the results of a number of measurements on alternating-current plant. Difficulties arising in the measurement of very small alternating-current voltages are overcome by rectifying the voltages so as to utilise sensitive direct-current instruments. The paper gives the result of some tests on two transformers of 3 kw. capacity intended to work between voltages of 100 and 1,000, and with currents of 100 cycles per second. One transformer was used to step up the volts from V_1 to V_2 the other to step down from V_2 to V_3. It was found that the phase difference between V_1 and V_3 for a non-inductive load increases regularly with the current. For an inductive load there is a sharply defined minimum at low power factor. The author suggested that points on one side of the minimum corresponded to a lag, and points on the other side to a lead of the current on the voltage in the primary circuit.

Dr. A. Hay congratulated the author, and said that the determination of power factors was a matter of importance. He had found that alternators tested with water resistances gave better results than when tested with lamps. The phase differences between the volts and the amperes in the water resistances were generally greater than those indicated by Dr. Sumpner. He asked the author what current density he used, and pointed out that the result would depend upon the current density at the electrodes. A minimum phase difference could be obtained by loading up the secondary of an ordinary transformer, and was due to an increase in the power factor up to a certain point and then a decrease. We were dealing with lag in both cases.

Mr. A. Campbell said that some years ago (Institution of Electrical Engineers, April, 1901) he published a description of the method of measuring a phase difference, close to 180deg., between two independent voltages by the first method mentioned by Dr. Sumpner—viz., by shunting the larger by a high resistance, picking off from it a part as nearly as possible equal to the other, and measuring the difference resultant. A test on a small transformer gave a phase difference of about (180°−0°·15). Dr. Sumpner, however, has considerably improved the method; he ensures the sufficient equality of the components by adjusting until the resultant is a minimum—a simple and beautiful device. In his discussion of the three-voltmeter method, Dr. Sumpner assumes that three instruments are necessary. Mr. Campbell has found that in many cases a single instrument with a quick change-over switch is quite sufficient, provided a number of readings are taken in rotation and averages obtained. With respect to Dr. Sumpner's method of measuring small alternating voltages by rectifying them, although it might give good results when the wave form was known, he thought that in the very cases where such measurements were wanted the wave form was not known. Small differences of "power" phase may be as much due to small difference in wave form as to small displacements of similar waves; thus the "difference" resultant is probably nearly always of very uncertain wave form.

Mr. T. H. Blakesley expressed his interest in the paper, and said that many years ago he had made use of commutation in order to work with direct-current instruments. He had used a high-resistance galvanometer, and found that not only the self-induction but also the capacity of the coils had to be eliminated.

Mr. W. Duddell supported Mr. Campbell in his contention that small differences of "power" phase might be due to small differences in wave form. He had used water resistances in testing large alternators, but had never found any phase difference between the voltage and the current. He had usually worked with high voltages, so that condenser effects due to polarisation (of the order of one volt) would have little effect.

Dr. C. V. Drysdale said he had given a good deal of attention to the measurement of small phase differences, and had found it advantageous to measure the sine of the phase difference instead of the cosine. This could be accomplished by putting a condenser in series with the pressure circuit of a wattmeter so as to produce a phase displacement of nearly 90deg. In these circumstance he had previously shown that with ordinary conditions the watts were equal to the wattmeter reading plus a constant multiplied by the sine of the angle of phase difference. When, as was usually the case, sin θ was nearly equal to unity, it was only necessary to add a constant to the wattmeter reading.

Dr. W. E. Sumpner, in reply to Prof. Hay, said he had worked with low current densities, and was unable to say what would happen if the current density was increased. With regard to rectification, he was aware of the effect of the shape of the wave. He had made experiments with currents of very different wave forms, and in his opinion only about 20 per cent. of the observed results could be due to any alteration in the form of the wave. His methods were suggested as a means of getting an *approximate* value of very small phase differences, which could not be determined in other ways. The difficulties referred to by Mr. Blakesley were not encountered, as he had worked with a moving-coil galvanometer of small capacity and self-induction. He was afraid that the observations of Dr. Drysdale raised questions which it would take too long to discuss at the present meeting.

LEGAL INTELLIGENCE.

PROPOSED FLOTATION OF AN ELECTRICAL INVENTION.

The case of Edwards and Brown *v.* Anderson and Hammond came before Mr. Justice Kekewich on Tuesday, the plaintiffs claiming £93, balance of account for services rendered under an agreement which plaintiffs alleged was made by the defendants.

Mr. McCall, K.C., said the plaintiffs had discovered an improved method of making conduits for electrical wires. In order to develop and work the patent and, if possible, form a company to work the invention, the plaintiffs were introduced to the defendant Hammond, who was secretary to several companies. Mr. Hammond suggested to the plaintiffs, who were quite unacquainted with the process of forming companies, that they should leave with him particulars of their invention, and that he would find someone who would go into the matter with him and form a company to work it. Plaintiffs were subsequently introduced to the defendant Anderson by Hammond, and were told that that gentleman would assist in finding the capital and promoting a company. Plaintiffs were induced to leave their employment, on the promise of the defendants that they would pay them their wages until the syndicate or the company came into existence, and it was on that contract that the plaintiffs claimed. From time to time the plaintiffs received some money from the defendant Hammond.

Evidence was given by the principals on both sides.

His Lordship, in giving judgment, held that the plaintiffs had not proved their case sufficiently, although he believed them to be truthful witnesses. He did not believe a word of the defendant Hammond's evidence. If, therefore, the evidence of the two plaintiffs had been up to the mark, he would have had no hesitation in giving judgment in their favour. As, however, the plaintiffs' case was not sufficiently verified, the case must be dismissed.

ACETYLENE GAS PATENT.

In the House of Lords on Tuesday, the Lord Chancellor and Lords Davey and Robertson had before them the matter of the Acetylene Illuminating Company, Limited, and the Willson Laboratory Company (appellants) *v.* United Alkali Company, Limited (respondent). This was an appeal by the Acetylene Illuminating Company, Limited, of 3, Victoria-street, S.W., and the Willson Laboratory Company (incorporated under the laws of the State of West Virginia, trading at 3, Beekman-street, New York, U.S.A.), against a judgment entered for the United Alkali Company when the action was tried before Mr. Justice Buckley and affirmed on appeal. In the action the Acetylene and the Willson Companies sought a declaration to restrain infringement by the United Alkali Company of letters patent No. 16,705 of 1894 granted to Thomas Leopold Willson. The patent related to an alleged invention of a new process for the manufacture of crystalline carbide of calcium, a chemical combination used chiefly for producing acetylene gas, which is obtained by the action of water upon calcium carbide. Mr. Justice Buckley held that the United Alkali Company had not infringed, on the ground that, in his judgment, the patentee had restricted himself to an arc furnace, whereas the United Alkali Company had used an incandescent furnace. In the Court of Appeal their lordships held that the patent was invalid for want of subject-

Digitized by Google

matter and on the ground of anticipation. The question, therefore, of whether there had been infringement was immaterial, and they did not decide it. Hence the appeal to the House of Lords.

In giving judgment, the **Lord Chancellor** said the appellants had failed to show that the invention was proper subject-matter for a patent. He had no hesitation in coming to the conclusion that the patent was invalid, because that was the view, and the only view, that had been taken of it by the judges in the courts below. Mr. Moulton had made a gallant struggle to establish that the utility and commercial value of the invention was such that although it only applied a known process of obtaining calcium carbide, it for the first time rendered that knowledge of commercial value, and, therefore, the invention ought to be protected. If that learned counsel had established what he so strenuously attempted to prove, he would have been entitled as the law stood to their judgment on that point. But he had not succeeded in his attempt.

Lords Davey and Robertson entirely concurring, the appeal was dismissed.

ELECTRIC TRAMCAR ACCIDENT.

At the Manchester Assizes, before Mr. Justice Phillimore and a common jury, the case of Edwards *v.* the Corporation of Manchester came on for hearing, in which the plaintiff claimed damages for an accident which happened to her whilst travelling in one of the Corporation's cars.

It was stated on the part of the plaintiff that at the time of the accident she was an inside passenger on a car which was proceeding in the Ardwick direction, and, as was her usual practice, intended to get down at Tipping-street. She told the guard this, she said, when she paid her fare. But when the car reached Tipping-street the guard was taking fares from the outside passengers. The car, nevertheless, stopped, and one or two gentlemen got out. The plaintiff got down to the bottom step, and, according to her account, had one foot on the roadway when the car made a sudden movement forward, and she fell. At first she felt no injury beyond the effects of a severe shake, but in a few days internal pain developed, and her medical attendant found that she was suffering from hernia, which, as she was about 65 years of age, he said, was likely to be chronic.

The question for the jury was whether there had been negligence on the part of the conductor, and, if so, whether this conduced to the plaintiff's injury. For the Corporation negligence was denied, and it was pleaded that the plaintiff had been guilty of contributory negligence in leaving the car whilst it was in motion. The conductor denied that he gave the signal for the car to start, and it was suggested that a passenger who left it immediately before the plaintiff got out did so improperly, or without noticing that she also was preparing to leave at the Tipping-street stopping place.

In the end the jury found for the plaintiff, damages £200; and his Lordship gave judgment for that amount.

CAPTIVE FLYING MACHINES.

Mr. H. Terrell, K.C., applied to the Chancery Division for an order for the compulsory winding-up of Sir Hiram Maxim's Electrical Engineering Company, Limited.

Counsel said the company, which was incorporated in 1899, contracted with the petitioner (Mr. C. Remmer) to erect at Southport certain parts of one of Sir Hiram Maxim's captive flying machines. He did the work and became entitled to payment of £1,576. He was given a cheque for £100 and bills for £964. The first bill became due in October of last year and was dishonoured. Mr. Hardy, managing director was appointed receiver on behalf of the debenture holders, and was afterwards made liquidator in a voluntary liquidation. Counsel asked, however, that a compulsory order might be made.

Mr. Eve, K.C., for the company, described the petition as idle and flimsy.

Mr. Justice Warrington thought the voluntary liquidation should be superseded by a compulsory order, and granted the application.

ALLEGED ELECTRIC SHOCK.

At the Manchester Assizes last week, before Mr. Justice Walton, Mr. W. S. Boor sought to recover damages from the Salford Corporation for personal injuries alleged to be due to an electric shock caused by the negligent management of the defendants' tramcars.

Mr. Shee, K.C., stated that the plaintiff boarded one of the defendants' cars while other passengers were getting in and out. With his left hand he grasped the canopy pole. Then the conductor touched the electric button as a signal to the motorman, and, turning to the plaintiff, he said something which the plaintiff took to be an intimation to take his seat. At that moment—the plaintiff having his hand still on the pole—the car began to move, and he received a violent electric shock. His body was "pulled up" or twisted, and he was unable either to release his hand or to move his left foot, which rested upon the step. The pain in his left leg was terrible. The guard and a gentleman who was seated inside the car went to his assistance, and he proceeded as far as the cattle market, but had to return home almost immediately in a cab. When seen by a medical gentleman (Dr. Dabbs) his left knee was swollen, and the conclusion arrived at was that there had been a rupture of the ligament. This was confirmed by an application of the X-rays. The shock had been sufficiently violent to produce this injury. The plaintiff remained under treatment, unable to leave his bed, for many weeks, and it was not until April 24 that he could proceed to Southport for change of air. There was every reason to think he would go on improving, but he was still an invalid. Amongst the out-of-pocket expenses which went to make up the claim were: doctors' bills, £40; physicians' fees, six guineas; X-rays and surgical appliances, £3; cost of nursing, £18. 15s.; five weeks' stay at Southport, £40; and loss of business for 21 weeks, £220. The total amount of these expenses came to over £900. Counsel added that he understood the defendants were going to say that the plaintiff was not injured by an electric shock at all, but by knocking himself against the rail or against the step when getting into the car. There could be no dispute, however, that electric shocks could be sustained through insufficient insulation, resulting in the leakage of electricity. This would be more likely to happen on a wet day, such as was the case when the accident occurred.

After evidence had been taken as to fact, a number of electrical and medical witnesses were called for the plaintiff.

Mr. Sanderson then opened the case for the Corporation, and said the latter did not insure passengers against all risks, nor did they warrant their cars to be free from all defects and absolutely safe. Their only liability in a case like this was that they should take reasonable care, having regard to all the circumstances. If the jury found that reasonable care had been taken, the defendants were not liable. The trams were run for the public benefit, and it would be a very serious thing if, when a corporation had used every possible precaution to ensure the safety of their passengers, they were to be penalised for accidents like this. The car in question was made in 1902, and was electrically equipped by the British Westinghouse Company, all the Board of Trade requirements being complied with. Before being brought into use it underwent the fullest and most complete tests. As to the plaintiff's injury, the defendant's explanation was that in trying to reach the platform of the car he slipped, and whether the injury was the result of a direct blow or in trying to recover himself was immaterial. It was while he was in the act of getting upon the platform that he cried out—that was to say, before the car moved. Counsel thought that after hearing witnesses the jury would say that it was practically impossible for the plaintiff to have got a shock in the way he had described. The car, as soon as the accident reached the cars of the Corporation, was exhaustively tested, and no leakage whatever could be detected about it. It was working to-day in the same condition as at the time of the accident.

Several well-known technical experts gave evidence on behalf of the defendants.

His Lordship, in summing up, said that the question was whether there had been negligence on the part of the defendants.

The jury, after a brief consultation, decided in the negative, and the action was therefore dismissed.

EMPLOYERS' LIABILITY ACT.

At the Brompton County Court Albert Fisher, a fitter's labourer, brought an action, under the Employers' Liability Act, against the Underground Electric Railways Company of London, Limited, Lot's-road, Chelsea, S.W., claiming damages in respect of personal injuries said to have been sustained owing to negligence on the part of the defendants or their servants.

Plaintiff's Counsel said that his client, who was in the employ of the defendants at their works at Lot's-road, was assisting in raising a heavy iron pipe from the ground on to a large staging. This staging consisted of iron columns, across which were scaffold poles, and across these were planks upon which the men stood. When the pipe was raised a little higher than the platform, a man in charge of the job called the plaintiff from the ground on to the platform. Suddenly the rope or sling by which the pipe was raised broke or gave way. The pipe fell on the staging, which collapsed. The men, including the plaintiff, fell some 30ft. or 40ft., the plaintiff sustaining serious injuries. Counsel contended that the staging was deficient, and particularly that the rope was defective. The defence filed by the other side was that the plaintiff had "exercised his option" by receiving half wages under the Workmen's Compensation Act. The plaintiff, however, had, while in hospital, signed a document agreeing to accept compensation under the Workmen's Compensation Act under the impression that he was merely signing a receipt for a temporary allowance.

The plaintiff supported his counsel's statements, and corroborative evidence was given.

For the defence evidence was called to prove that the plaintiff distinctly understood he was being compensated under the Workmen's Compensation Act.

The jury returned a verdict in favour of the plaintiff, assessing the damages at £81. 16s.

SHEFFIELD ELECTRICITY WORKS.

At the Sheffield County Court last week Joseph Bolton, herbalist, sued the Corporation of Sheffield for £2. 10s. on account of damages sustained by him owing to their allowing an emission of fine dust from the chimney of their electric power station in such quantities as to be nuisance in law, such fine dust falling upon the plaintiff's goods and damaging them.

Mr. Muir Wilson, in opening the plaintiff's case, said that the injury complained of was particular and beyond that suffered by the general public. On June 14 plaintiff had his stall in the Sheaf Market, on which his goods were exposed to view. From two o'clock until five there was a continuous emission of very fine grit from the chimney of the electric power station. Whether it arose from improper fuel or not, he could not say. It spoiled him six varieties of herbs and some pills. It was impossible to cover these articles up, as that would have spoilt the sale. He drew the attention of the market collector to the matter. On Aug. 9 there was a repetition of the emissions.

For the defence it was stated that every precautionary measure known to science had been taken.

Evidence was given on both sides as to question of fact, and the defendants called witnesses upon technical points.

Digitized by Google

His Honour, in giving judgment, said at the close of plaintiff's case he had very grave doubts whether the plaintiff had made out a case, but he was glad he had not interfered, because the case had now been gone into very thoroughly, and they had had a large body of evidence upon it. The argument addressed to him on behalf of the plaintiff was entirely based on the assumption that the grit complained of had come from the chimneys at the power station. That was an assumption which had not been borne out by a single witness. The statement of the young man who, in giving evidence on behalf of the plaintiff, spoke of "showers of grit" was an exaggeration, to say the least of it. The plaintiff's case was entirely disproved, and instead of nonsuiting, as he should have been inclined to do on the previous day, he found that the defendants had made out their case completely to his satisfaction, and there would be judgment for the defendants. As to costs, he would point out that there were 25 other chimneys in the neighbourhood, every one of which, according to the evidence, did, and probably must, eject grit, and that it was quite possible that plaintiff might reasonably have thought that it was coming from the Corporation's chimneys.

In the circumstances, **Mr. Ellison**, for the defendants, said he would not press for costs, and judgment was therefore given for defendants without costs.

OBSTRUCTING A TRAMCAR.

At the Leicester Police Court last week, B. Peacock, greengrocer, was summoned for driving his horse and cart in such a manner as to obstruct the Corporation tramways.

The town clerk, Mr. E. V. Hiley, prosecuted, and defendant pleaded not guilty.

The Tram-driver said he was driving a car in the East Park-road route down the Humberstone-road on the afternoon of the day in question. When near the railway bridge he saw a horse and cart proceeding along the track in front of him, of which the defendant was the driver. Witness rang his bell several times, but he took no notice whatever. Witness drove behind him, sounding the gong all the time, as far as the Forest-road, over 200 yards. Defendant turned round twice and laughed.

Corroborative evidence was given by a passenger.

Defendant was fined 40s. or a month.

OLD TRAMWAY TICKETS.

At the Nottingham Summons Court, William Payne was summoned for attempting to avoid payment of a tram fare. Defendant pleaded guilty.

Mr. H. W. Day, of the town clerk's office, said that defendant got in at Great Alfred-street, and after the car had proceeded for some distance the conductor went round in the usual way to collect the fares. He went to the defendant, who said he had paid and held out a ticket. The conductor passed on, but feeling doubtful went again to defendant, who repeated what he had said before. Later an inspector boarded the car, and examined the tickets. Defendant showed him the same ticket, which had been issued at Trent Bridge on the same journey, and had exhausted itself at the Market-place. It was clear that defendant had picked up the ticket; in fact, he afterwards admitted to the inspector that he had done so.

A fine of 2s. 6d. was imposed.

THEFT OF TELEGRAPH WIRE.

At Brentford Police Court on Saturday, Thomas Newman and Arthur Ballard were charged on remand with unlawful possession of a quantity of telegraph wire belonging to the Postmaster-General.

The prisoners elected to be dealt with summarily, and, on account of previous good character, they were bound over under the First Offenders' Act to come up for judgment if called upon.

COMPANIES' MEETINGS AND REPORTS.

BRITISH WESTINGHOUSE.

The report of the British Westinghouse Electric and Manufacturing Company, Limited, for the year ended July 31, 1904, shows a profit of £50,550. After providing for debenture and loan interest and for the further items set out in the profit and loss account, a balance of £2,809 remains, which the directors propose to carry forward. A considerable sum for the maintenance of the large machine tools has been charged to revenue during the year, and latterly patterns, drawings, etc., have been charged to revenue. The directors, therefore, are of the opinion that the sum of £10,500 provided for depreciation is sufficient to meet requirements. The buildings have been well maintained, and, in the opinion of the directors, no special provision for depreciation thereon is at present necessary. The Board have not deemed it necessary to write off any depreciation on patents, in view of new ones that have been taken out. At the general meeting in February last the capital of the Company was increased by the creation of a further 100,000 6 per cent. preference shares of £5 each. These have been taken up and paid for in full at par by the American Westinghouse Company. In addition to this, but since the closing of these accounts, the American Westinghouse Company has taken up and paid for at 95 per cent. £400,000 4 per cent. mortgage debenture stock. Since Aug. 1 last the temporary loans have been repaid, and the amount due to sundry creditors has been considerably reduced. The result obtained at the close of this the first complete year of manufacturing has shown that the general expense and outlay incident to the development required in connection with the Company's plant at Trafford Park has been much greater than the management anticipated. The varied, and to a large degree novel, character of the work undertaken more than a year ago required additions in equipment of many kinds, and the expense met with in forming the organisation required to execute such work has involved considerable outlay. These expenditures have, however, placed the factory in an advantageous position to execute orders in the future for large generating units. A larger amount of work is now being turned out for a smaller amount of labour than formerly, and a matter of equal importance is that the proportion of contracts executed in the works, as compared with finished material purchased from other manufacturers to fill such contracts, is increasing, while at the same time the margin of profit on work executed in the factory is moving upwards. While it is not possible to declare a dividend upon the preference shares, the outlook is one which encourages the directors to look forward to an improvement during the current year. Orders received during the year ended July 31, 1904, totalled £927,336, as against £1,657,114 in the preceding year. The Company has taken orders during the first three months of the current year aggregating £311,000, as compared with a total of £210,000 for the corresponding period of last year.

WEST INDIA AND PANAMA TELEGRAPH.

The report of the West India and Panama Telegraph Company, Limited, for the half-year ended June 30 last, to be submitted to the meeting on the 30th inst., states that the amount at credit of revenue account is £34,581, a decrease of £322. Expenses have been £23,437, an increase of £386, leaving a balance of £11,144, to which is added £1,825 (interest on investments) and £711 (brought from last account), making a total of £13,679. It is proposed to pay a dividend of 7s. per share on account of arrears to June 30, 1904, on the first preference shares, carrying forward £1,582. This will leave the following dividends in arrear: on the first preference shares £1,728, and on the second preference shares £11,205. Expenses of repairing cables during the half-year amounted to £8,539, being £1,211 less than those for the corresponding period. This is, however, exclusive of a further expenditure of £3,468, which has been charged to reserve, in respect of 40 knots of new cable used in February last in the repair and partial renewal of the St. Lucia-St. Vincent section, which, it will be remembered, was interrupted by volcanic disturbances in September, 1902. The Company's repairing steamer "Henry Holmes" was chartered to the Cuba Submarine Telegraph Company in September last to repair one of their cables, but the charter has since expired and the ship has resumed her ordinary work on the Company's system. The Danish colonies of St. Thomas and St. Croix have renewed their subsidies for a further term of five years. West India commercial prospects are reported to be favourable consequent upon the abolition of the sugar bounties. The improvement to be expected therefrom has, however, not had time to make itself felt in the traffic receipts of the Company.

MAY-OATWAY FIRE APPLIANCES.

The third annual report shows a profit, after providing for depreciation of stock and plant, of £2,033. 13s. 3d., equal to a dividend of about 6 per cent. upon the issued capital of the Company. The directors are now able to make good the deficiency of £1,765. 3s. 2d. which accrued during the earlier years of the Company, when it experienced serious difficulties, which have now, happily, been overcome. Since the last general meeting the Company have put in some of the largest installations of automatic alarms in existence, and the directors believe that that supplied to Messrs. J. and P. Coats, Limited, constitutes a world's record, while the preference shown for the Company's appliances by the great railways and manufacturers having expert engineering departments, and the orders received for repeat installations or extensions from the Corporation of the city of Glasgow, Messrs. Harrods, Limited, J. and B. Stevenson, and others must also be regarded as highly gratifying. The favourable fire loss experience has been maintained, and in no case where an outbreak has originated in any building protected by the Company's system has damage exceeded nominal figures. Application has recently been made to the London County Council for permission to transmit to the metropolitan fire brigade stations calls received from the Company's various City installations, and terms have been received which are now under consideration. Several additional fire brigade stations have been fitted with the Company's apparatus, and protected buildings have been placed in connection therewith. The stations so fitted include the Edinburgh, Belfast, and Aberdeen central stations and the Glasgow eastern, western, northern, and southern district stations; and outfits are being prepared for equipping the district stations in Edinburgh to which protected buildings are waiting to be connected. Meanwhile, shareholders will be glad to know that the experience of the fire departments with which the Company have numerous properties connected has been favourable, and that their goodwill and recommendation continue—a high tribute to the essential merits of the system. The directors consider that the time has now come to apply to the influential associated fire offices for reductions of premiums, and they purpose lodging within the next few days an influentially signed petition asking the tariff companies to authorise in the United Kingdom the rebate already given by them to users of the May Oatway system in New Zealand, the country of its origin. Already concessions are granted to users of the Company's system by non-tariff offices, but the industry will only assume its rightful proportion and status when the tariff companies recognise the benefit of the safeguards provided by lowering the charges for the risks. Agency arrangements have been entered into with the Société

Digitized by Google

Industrielle des Telephones, Paris, to develop the French patent rights. The directors have extended their agency arrangements in various parts of the United Kingdom, and have opened branch establishments in Glasgow, Liverpool, and Manchester. Every endeavour is being made to develop the business of the Company, and with the advantages of a growing *clientèle*, well-assorted stocks, an invention commercially and scientifically proven, and no arrears of capital to make good, the Company should be dividend-paying at an early date.

NEW COMPANIES REGISTERED.

H. F. Hill, Limited.—Registered Nov. 19. Object: to acquire certain patents from Mr. H. F. Hill, and to carry on the business of electricians, mechanical engineers, suppliers of electricity for light, heat, motive power, or otherwise, manufacturers of and dealers in electrical apparatus, contractors for tramway, electric railway, and other works, etc.

Fletcher Bros. (A-u-L), Limited.—Capital, £35,000. Object: to acquire and carry on the business at Ashton-under-Lyne of Fletcher Bros., as brassfounders, brass engineers, valve makers, manufacturers of boiler mountings and fittings, gas and oil engine manufacturers, electrical and gasworks plant manufacturers, mechanical, electrical and hydraulic engineers. Registered office: Blandford-street, Ashton-under-Lyne.

Mercedes Motor Works, Limited.—Capital, £2,000. Object: to acquire a license from the Mercédès Company, Limited, for the manufacture in Great Britain of Mercédès engines for motorcars, motor boats, and other purposes, and to carry on the business of manufacturers and sellers of and dealers (as principals or agents) in oil, gas, spirit, and electrical motors and machines, electricians, engineers, mechanicians, rubber manufacturers and merchants, etc.

Lindsey Light Railways Syndicate, Limited.—Capital, £1,000. Object: to apply for and obtain orders for a light railway, under the provisions of the Light Railways Act, or other statute, between Blyton and Frodingham, Lincolnshire, and to carry on the same.

Moorwoods (Manchester), Limited.—Capital, £3,000. Object: to carry on the business of builders' merchants, mechanical and electrical engineers, etc.

Cheshire Light Railways, Limited.—Capital, £1,500. Objects: to obtain from the Light Railway Commissioners or other authority any orders authorising the construction of light railways in Cheshire or elsewhere in the United Kingdom or abroad, to adopt an agreement with R. H. Scotter, and to carry on the business of light railway proprietors, manufacturers of and dealers in railway and tramway carriages, motorcars, omnibuses, locomotives, and engines, etc.

Chameleon Signs, Limited.—Capital, £2,700. Object: to adopt an agreement with M. J. Pearce and W. R. F. Avery, and to carry on the business of manufacturers of and dealers in signs and advertising devices made in accordance with an invention mentioned in the said agreement, manufacturers of and dealers in general electrical, mechanical, automatic, and optical devices, etc. Registered office: 318, Dashwood House, E.C.

Lanchester Motor Company, Limited. — Capital, £50,000. Object: to acquire the undertaking of the Lanchester Engine Company, Limited, and to carry on the business of manufacturers of and dealers in motors and engines of every description, whether worked by oil, electricity, or other power, builders of carriages, wagons, tramcars, etc.

Liens Registered.

Kensington and Knightsbridge Electric Lighting Company, Limited.—A trust deed, dated Nov. 2, 1904, issued jointly with the Notting Hill Electric Lighting Company, Limited (supplemental to a trust deed dated July 12, 1900, covering £100,000, and a further trust deed dated Nov. 18, 1902, covering £50,000, both issued jointly by this company and the Notting Hill Electric Lighting Company, Limited), to secure a further £50,000 debenture stock, ranking *pari passu* with the two former joint issues, has been registered. Trustees—R. B. Martin, M.P., 68, Lombard-street, E.C., and G. H. Hopkinson, 93, Pimlico-road, S.W. Property charged—Freehold generating station belonging jointly to this company and the Notting Hill Electric Lighting Company, Limited.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Madrid.—The General Telegraph Office require tenders for installation and working telephones in the town of Talavera. Tenders to above by Dec. 7.

Guirgia (Roumania)—Tenders are required for the electric lighting of the town. Particulars from the town's secretary. Tenders by Jan. 28, 1905.

Kilmarnock.—The Corporation are prepared to receive tenders for the sole right of advertising on their tramcars. Tenders by Dec. 6. See advertisement.

Salamanca.—The Municipality require tenders for public electric lighting of the town. Tenders by Dec. 12 to above or to Direccion-General de Administracion, Madrid.

Edinburgh.—The Corporation invite tenders for the electric lighting installation at the branch free library, Morningside-road, Edinburgh. Tenders by Dec. 14. See advertisement.

Erith.—The Urban District Council invite tenders for motorcars, trucks, motors, and equipments, track sweeping and watering car. Tenders by Dec. 19. See advertisement.

Swindon.—The Corporation invite tenders for the supply and erection of one 300-kw. steam dynamo, or, alternatively, one 400-kw. steam dynamo. Tenders by Dec. 20. See advertisement.

Madrid.—The Public Works Branch of the Department for Agriculture require tenders for construction and working of an electric tramway between Azeritia and Zumaya. Tenders by Dec 10.

Bradford.—The Corporation invite tenders for the supply of miscellaneous stores required by the tramways department during the year ending Dec. 31, 1905. Tenders by Dec. 17. See advertisement.

Caen (France).—The Prefect requires tenders for concession of a tramway from Ryes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1, 1905.

Llandilo (Wales).—The Urban District Council invite tenders for testing and calibrating the electricity meters installed in the town (70 in number). Tenders to Mr. R. Shipley Lewis, clerk, Llandilo, before Dec. 6.

St. Marylebone.—The Council invite tenders for the purchase of 1,000 house transformers, of from 1 to 5 kw. capacity, together with a quantity of scrap cable and old cut-outs. Tenders by Dec. 5. See advertisement.

Madrid.—The call for tenders for the service of the electric lighting of Almendralejo was without result. The conditions of contract have, therefore, been modified in certain respects, and tenders are to be called for to be opened on Dec. 22.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

London, S.E.—Tenders are invited for the erection of an electrical traveller to lift 12 tons over a span of 40ft. Persons desirous of tendering should send their names on or before Dec. 10 to B. E. Nightingale, Albert Works, Albert-embankment, Lambeth, S.E.

Fulham.—The Council require tenders for the supply and erection of a 3,000-volt steam alternator of 1,000 kw. capacity, coupled to a Belliss engine, at their generating station, Townmead-road. Tenders to Town Clerk not later than 12 noon on Dec. 20. See advertisement.

Johannesburg.—The Municipal Council invite tenders for two 35-ton electric overhead travelling cranes and transformer pillars and switchgear. Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W., and received by them not later than Dec. 27.

Glasgow.—The Corporation invite tenders for electric light installation, etc., for Dennistoun district library. Specifications and forms of tender may be obtained on application to Mr. James R. Rhind, 67, Hope-street, Glasgow, and sealed tenders must be lodged with Mr. James G. Monro, town clerk, City Chambers, Glasgow, by 10 a.m. on Dec. 5.

Stockport.—The Guardians invite tenders for providing and fixing electric light (wiring only), telephones, and bells required at the new infirmary, Stepping Hill. Plans and specification may be seen and all other information obtained from Mr. W. H. Ward, architect, Paradise-street, Birmingham. Tenders to Mr. Charles F. Johnson, clerk, and to be delivered by 10 a.m. on Dec. 12.

Valladolid.—Tenders are required for the public lighting by means of electricity of the city of Valladolid. Fifteen hundred incandescent lamps of 17 c.p. will be required. The concession will terminate on Dec. 31, 1911. The annual payment to the concessionnaire will be about £965. A deposit of £48 is required to qualify any tender. The adjudication will take place at 11 a.m. on Dec. 26, at the Casa Consistorial, Valladolid.

Perth (Australia).—Tenders are invited by the Duputy-Postmaster-General for the supply of the following telephone material; 19½ miles 26-pair lead-covered cable, dry core, to standard specification No. 7; 5,000 paper sleeves, 3in. long by $\frac{3}{8}$in. diameter; 350 yards paper strips, 2in. wide. Conditions, etc., may be obtained at the General Post Offices at Perth, Adelaide, Melbourne, Sydney, Brisbane, and Hobart. Tenders by Dec. 28.

Shanghai.—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

Bromsgrove (Worcs.).—The Visiting Committee invite tenders for the supply and erection at their new lunatic asylum of the following plant: (Section A) engines, dynamos, booster, and steam services; (B) storage battery and accessories; (C) main switchboard, ring main, feeders, distribution boards, wiring, lamps, and accessories. Specification, etc., may be obtained from Mr. Robert J. Oliver, clerk of the Visiting Committee, Shirehall, Worcester, on payment of £5 for each section of the work as above, which will be returned on receipt of a bona fide tender.

Madrid.—Tenders are invited for the public lighting by means of electricity of the town of Villanueva y Geltru for a term of 10 years. Twenty-four arc lamps of 500 c.p. and 239 incandescent lamps of 20 c.p. will be required. The concessionnaire will be allowed to supply private individuals without payment of a municipal tax subject to his supplying, free of charge, the Casa Consistorial with 75 kw. per month. He will be required to maintain a duplicate set of machinery in order to avoid the possibility of the town being left in darkness through a breakdown. The annual payment (upset price) to the concessionnaire will be 23 145 pesetas (about £678). The adjudication will take place on Dec. 24. A deposit of £68 is required to qualify any tender.

Digitized by Google

Madrid.—The *Gaceta de Madrid* of Nov. 9 publishes a notice inviting tenders for the construction and working, for 60 years of an electric tramway between Azcoitia and Zumaya (Province of Guipúzcoa), in accordance with certain conditions set out in the *Gaceta*. An application for this concession has already been received from Don Dionisio Sorseta Garcia, who, at the same rates, will enjoy certain preferential rights over other tenderers. The competition will turn, in the first place, on the reduction of the tariff fixed for the conveyance of passengers, etc.; in the event of equal terms being offered, it will turn on a reduction of the period of concession. Adjudication of tenders will take place before the Director-General of Public Works, Madrid, on Jan. 10. A deposit of 16,297 pesetas (about £475) is required to qualify any tender

Brisbane.—Tenders are invited by the Deputy Postmaster-General for the supply and delivery at the Telegragh Office Yard, Thursday Island, of 100 tubular wrought-iron telegraph poles to Specification No. 11 and Schedule No. 51, and also for the supply and delivery at the cable tanks, Thursday Island, of three nauts of submarine cable to Commonwealth Specification No. 8 (Queensland, No. 22) and Schedule No. 50. Tenders by Dec. 12. They must state the time required for delivery; this time will be counted from the date of the notification of the acceptance of the tender. Specifications and forms of tender can be obtained at the General Post Offices, Sydney, Melbourne, Brisbane, and Adelaide. Neither the lowest nor any tender will necessarily be accepted. Tenderers are required to note that Customs' duties must be included in all charges, as per clause 2 of the general conditions. All tenders sent by post must be registered.

RESULTS OF TENDERS.

Torquay.—We understand that the Council have accepted the tender of the Alphons Custodis Chimney Construction Company, at £3,719, for the erection of the chimney stack at the new generating station.

Dundee.—The Town Council have accepted the tender of the British Insulated and Helsby Cables, Limited, at £2,749. 17s., for the relaying of the present copper strip feeder main throughout the town with insulated cables.

Middlesex.—The County Council have accepted the tender of the Hart Accumulator Company, Limited, Marshgate-lane, Stratford, E., for the supply of storage battery of 115-1,050 ampere-hour standard lighting type cells for Napsbury Asylum.

Belfast.—The Tramways Committee have recommended for acceptance the following tenders: J. G. White and Co., London, permanent way, road bed, paving, and bonding £280,643. 12s. 4d., overhead electrical equipment £38,809. 15s. 5d., underground feeders, telephone and test wires, and spare conduits £65,263. 16s. 8d. (in consideration of getting these three contracts, the firm agree to deduct £1,000 from the total amount of their tenders); British Westinghouse Company, steam dynamos, switchboard, three-phase plant, condensing plant, overhead traveller, and station lighting, £40,933. 5s.; Fairbairn, Lawson, Combe, and Barbour, boilers, superheaters, mechanical stokers, economisers, coal and ash conveying plant, steam, exhaust, and feed pipes, and pumps, £19,740 (subject to the special condition that any work done in the firm's own foundries under this contract shall be done in Belfast); Brush Electrical Company, double-deck electric tramcars, £93,642.

BUSINESS NOTES.

TRACTION.

South Shields.—The Council are considering the question of starting the construction of the tramways at an early date.

Wicklow.—An order in Council has been granted for the construction of tramways, with which Lord Fitzwilliam is closely associated.

Ayr.—The tramway manager is to report upon the advisability of now proceeding with the extension of loop at Chapel Park and loops in Carrick-road.

Middlesex County Council.—At a meeting of the Council the other day it was stated that the Edgware-road and Finchley lines were practically completed.

Croydon.—The Camberwell Borough Council favour the proposed tramway extension to the Crystal Palace, of which we gave particulars in our issue of the 11th ult.

Glasgow.—It has been decided to proceed at once with the construction of the extension from Pollokshaws East to Giffnock. The work will be done direct by the department.

Bath.—The tramway company propose to apply to the Board of Trade for powers to extend their line to Newton St. Loe. The local authorities are understood to be favourably disposed.

Western Telegraph Co.—The directors have declared an interim dividend, payable on Dec. 21, of 3s. per share, or at the rate of 6 per cent. per annum, free of tax, for the quarter ended Sept. 30.

Sunderland.—The Tramways Committee have decided to recommend the Council to have an additional loop made at the east end of the town at a cost of £391. This will enable a 10 minutes' service to be run.

West Ham.—The Works Committee of the West Ham Corporation have commenced the relaying of the tramway lines in the Romford-road preparatory to the length between Stratford and Forest Gate being electrified.

Jarrow.—The British Electric Traction Company's tardiness in proceeding with the tramway scheme is resented by the Town Council, who have decided to vigorously oppose the company's applica ion for an extension of time.

Proposed New Tramway.—It is reported that a tramway has been virtually decided upon from Westbourne to Swanage, near Bournemouth. Private enterprise is responsible for the scheme, which is estimated to cost £68,000.

Hastings.—It is reported that the tramway company intend to seek powers to use the overhead in lieu of the conduit system, both on financial and engineering grounds. The proposed change appears to have excited considerable disfavour locally.

Cardiff.—The question of completing the connection of the Penarth-road tramways with Mill-lane has been referred back to committee. The committee have prepared a new scheme of fares embodying considerable increases. The matter has to come before the Council for their decision.

Maidstone.—The Town Council have decided to promote a provisional order for the following extensions: a line from the top of High-street, up Week-street and Boxley-road, to Penenden Heath and Holland-road; and from the top of High-street, down Gabriel's-hill and Stone-street, to the Loose-road.

Darlington.—It has been decided to issue books of tickets at a reduction of 10 per cent., and a sub-committee has recommended experiments with ½d. fares. A member of the Council proposes that a line should be run right into the station and also along Crown-street, enabling the trams to carry the mails.

West Cumberland Electric Tramways.—It is reported that application is to be made for an extension of time to construct this line. The scheme has been dormant of late, but it is stated that a commencement will be made early in the spring, the financial and other arrangements having been proceeded with.

Devonport.—An enquiry has been held into an application by the Devonport and District Tramways Company for power to extend their tramway at Pennycomequick to the borough boundary at Devonport, and from that point to construct a light railway or tramway through Saltash-road and Cobourg-street to Pound-street, Plymouth.

Halifax.—The borough accountant's report on the Corporation's trading undertakings has been presented to the Finance Committee. For the six months ending Sept. 30 the tramways show a profit of £4,706, representing a substantial increase over the corresponding period of last year. Most of the other enterprises showed losses.

Rochdale.—The Healey section has been approved by the Board of Trade and opened to the public. In connection with the system lately owned by the company, it has been agreed between the authorities concerned that the Littleborough section, which since the transfer has been worked jointly, shall now be worked by the Rochdale Corporation on its own account.

Swansea.—It is stated that the Swansea Gas Company has a bill for nearly £2,000 against the Corporation as the cost of relaying their mains in certain streets, consequent on the tramways extension work. Arbitration proceedings in connection with the property owned by Mr. Graham Vivian, which the Corporation are to acquire for tramway extensions, have been held.

Electric Tramways for Spain.—Notices are published in the *Gaceta de Madrid* of applications for concessions to lay electric tramways in Vigo by Don Alvaro L. Mora, from the Calle de Esparteros to the Puerta del Sol (Madrid), by the Compañia Eléctrica de Tracion, and in La Malvarrosa (Valencia) by the Sociedad Colonia Sanatoria de la Playa de la Malvarrosa.

Newport.—Stoppage of the tram service for 1½ hours occurred at Newport the other day. It was due to an obstruction of the flow of water for working the engines at the power station in Corporation-road. The deputy electrical engineer and tramways manager was soon on the spot conducting investigations, with the result that the cars resumed running with as little delay as possible.

Belfast.—It is stated that the arbitrator, Mr. L. L. Macassey, M.I.C.E., has arranged for the arbitration proceedings in connection with the transference of the tramways to the Corporation to take place in London. The sittings will be held in January next. At a special meeting the Tramways Committee made their recommendations in regard to the acceptance of tenders, of which particulars appear in another column. The contracts, six in number, represent a total of £538,000.

Halesowen.—The District Council have decided to apply to the Board of Trade for an extension of the orders secured in 1901 and 1902, under which they have the power to commence and complete the construction of tramways in the district for a period of 12 months from Dec. 18. The Council have leased their powers for the construction of light railways and the supply of electricity to the Empire Electric Lighting Company, but considerable dissatisfaction exists in the district owing to the fact that the period specified in the agreement expired about two months ago, and no definite action has been taken by the company.

Erith.—The Tramways Committee paid a visit to Bexley the other day and inspected the tramway system of the district, including the car-sheds, cars, permanent way, and generating station. The officials of the Bexley Council furnished all the particulars and information desired. The consulting engineers have reported to the Council that at Bexley-road about half a mile of line has been laid down and a good start made with the paving, and at Abbey Wood a considerable length of road has been opened, and platelaying and concrete are well in hand. Steady progress is being made with the system generally. The deputation appointed to visit several provincial tramways have presented their report.

Leith.—The Tramways Committee had under consideration on Wednesday estimates and specifications for the rails to be used in the reconstruction of the tramway system. Members of the committee

Digitized by Google

seem to be of opinion that the streets should not be disturbed until after the New Year holidays, but it is reported that a start will be made early in January. It is proposed that the section along Pilrig-street and Newhaven-road to Bonnington be dealt with first in two parts, so that either horse or electric cars can be run on this section while the work on the other portions is in hand. When the Pilrig-Bonnington lines are completed, the Ferry-road, Junction-road, and Leith-walk route will be proceeded with. It is hoped that the reconstruction will be practically completed in July or August of next year.

Handsworth.—Sir Colin Scott Moncrieff is proceeding with the arbitration which is to settle the price the District Council shall pay for the portion of the undertaking of the City of Birmingham Tramways, Limited, running from the Aston borough boundary to the terminus at Perry Bar, and what rolling-stock the Council shall purchase. Evidence has been given by Mr. G. Conaty (manager) and Mr. A. H. Dickinson (consulting engineer), of the tramway company, and Mr. Robert Green (civil engineer) as to the initial cost and depreciation of the rails, concrete bedding and granite pavement, and rolling-stock. Mr. Conaty said there was a special demand for old tramrails for colliery purposes, and he had sold them as high as £4 per ton. The bedding might have given way in one or two places, but the concrete was as sound as ever. After beginning the evidence of Mr. J. Waugh, engineer, of Bradford, on behalf of the Council, the proceedings were adjourned until the 22nd inst.

Ashton and Stalybridge.—Another conference has been held in reference to the deadlock between these authorities. The negotiations again proved abortive, owing, it is reported, to the attitude of the Stalybridge, etc., Joint Board. The chief obstacle was the Scotland-street route, concerning which Ashton made the following alternative propositions: (1) Ashton Corporation to construct and maintain the Scotland-street tramway route, pay all loan charges, sinking fund, and any other expenses excepting rates and taxes, the Joint Board paying to the Ashton authorities the sum of £450 per annum, plus an agreed price for current taken, and all rates and taxes; or (2) the Ashton Corporation will construct this length of line, the Joint Board to pay all loan and other charges thereon, including rates and taxes, a fixed sum for current taken, and an annual sum to the Ashton Corporation of £250, the Ashton authorities undertaking to maintain and keep the line in good working order. Nothing was arranged, however, and the matter remains in abeyance.

Crystal Palace.—At the meeting of the Crystal Palace Company the other day, the chairman had a good deal to say upon the subject of traffic facilities, of which there are signs of considerable development in the neighbourhood. The London County Council have decided to meet the request of the Croydon Corporation by completing the intended line to the Palace from South Norwood. Then there is a probability, the chairman stated, of the County Council undertaking at no distant date the extension of its South London system to the Palace. Moreover, the Croydon and Beckenham extension to the Penge entrance, already authorised, may be commenced shortly and be in operation by next May. Ultimately, the chairman believed, they would obtain a large network of feeder lines, which was essential to the substantial success of the Palace. There is, in fact, a prospect of extensive traffic in this locality, which will probably have the effect, among other results, of bringing to the famous Sydenham resort the success anticipated by the chairman.

Ipswich.—The receipts from the Corporation trams have fallen a good deal lately. The first big drop in the receipts took place in the week ending Sept. 17, the income falling to £552, as compared with the previous week's £605. The following week there was a drop to £508, or £97 down in a fortnight. Then came drops of £24, £40, and £27 in quick succession, making a reduction in takings between Sept. 10 and Oct. 15 of £191. Then came a modification of the service, presumably to save expense, and the receipts for three weeks were steady, followed by a drop of £43 in the week ending Nov. 5. The following week came a slight rise, and on Nov. 14 the final alterations for the winter service took effect. There was a further drop of £48 on the next week's takings, and for the week ending the 19th ult. there was another drop of £37. Comparing the last-mentioned week with the last week of September there was a fall of £218. The weather has, of course, been less favourable for travelling lately as compared with the summer months, but the difference in receipts is very considerable. There appears to be a good deal of friction with the motormen and conductors.

New Electric Railways.—Amongst the new schemes parliamentary notices have just been issued regarding powers to be sought in the next session to construct two new electrical railways. The first is to be known as the North-East London Railway, and aims at linking up the city with Essex and Hertford, taking in *en route* some of the more populous centres. It is to start from the corner of Eastcheap, and run on to Bishopsgate-street Within and to Shoreditch, then to Hackney, proceeding thence to Southgate and Waltham Cross. The generating stations are to be situated at Hackney and Leyton, close to the recreation ground at the latter place. The second line is drawn on a larger scale. It is entitled the Hammersmith, City, and North-East London Railway. The starting point will be at the junction of King-street West with the Broadway, and the line will go thence to Westminster, with a station in Piccadilly. Gracechurch-street is the next point, and then High-street, Stoke Newington, and Southgate. At Stoke Newington it is intended to branch off to Walthamstow. The gauge suggested is 4ft. 8½in., and it is proposed to erect generating stations at Hammersmith and Kingsland-road, Shoreditch.

Snowdon-Bettws-y-Coed.—The Board of Trade have now finally sanctioned the order for the proposed electric railway from Bettws-y-Coed to the junction with the new Beddgelert and Portmadoc line, the construction of which is being rapidly proceeded with. The promoters of the first-named railway have arrived at a settlement with the Bettws-y-Coed Council with respect to the tunnelling at the Swallow Falls and the level crossing in the village of Bettws-y-Coed. It is understood that the work on this line will be begun in the course of a few months, but in the meantime all energy is being concentrated upon the section of railway down to Portmadoc, which, should the winter be reasonably mild, will probably be finished and opened for traffic at the beginning of next summer, as well as the extension of two to three miles in length as far as the Snowdon station at Rhyd Ddu, the terminus of the old narrow-gauge line, past Llyn Cwellyn to Dinas, on the London and North-Western Railway near Carnarvon. Meanwhile the works of the North Wales Power Company, who are to supply the power, are going ahead with great activity, and it is anticipated that energy will be available by the time the first section of railway is ready. It is intended in due course to electrify the narrow-gauge railway down to Dinas, and to extend the line from Dinas to the Carnarvon Quay. Powers have also been obtained for another light railway from Bettws-y-Coed to Corwen, on the Great Western line, which is also to be operated with current from the Snowdonian power station. The power company intend to construct an embankment at Llydaw for the purpose of increasing the storage capacity of the lake, but this work will not be begun until the line of pipes down to the generating station has been used to lower the level of the lake, and so drain off the water which now saturates the ground on which the embankment will be raised.

Exeter.—The Mayor, accompanied by members and officials of the Corporation, laid the corner stone of the car-shed and offices for the electric tramways on Saturday. His Worship congratulated Messrs. Dick, Kerr, and Co., the contractors, on the able manner in which they were undertaking the work of construction. He hoped that arrangements would be able to be made at a round table conference with the authorities of the growing suburb of Heavitree, which would result in the tramways being continued to Heavitree Park as scheduled in the Act. The length of permanent way under construction is 5½ miles of single track. The amount of the contract for the tramways is £29,227; that for the electrical equipment, including the overhead system, £5,471; the 12 cars, which were being constructed, at a cost of £6,933; and the foundations for the car shed and the superstructure will cost £5,395—totalling about £47,000. The car-shed will have accommodation for 22 cars. For 22 years, remarked his Worship, Exeter had been obliged to put up with a very inefficient and very inadequate service of tramways. Two years ago people were surprised at the statements which he made from Board of Trade returns, that for the year ending June 30, 1902, the present horse tramways carried 407,000 passengers, and the 'buses 42,000, whilst the takings of the tramways amounted to £1,690; but during the nine months that the Corporation had worked the tramways they had carried 414,645 passengers, and the takings amounted to £1,730, so that if in 12 months they could carry close on half a million people with such an inefficient and inadequate service, handicapped as it had been during the past three or four months by the work of reconstruction, he thought they might justly assume that electric tramways extending from Heavitree to St. David's on the one side, and from the cemetery to Dunsford Gate on the other, would amply repay the citizens for the capital the city was expending upon them.

Trafford Park.—The following interesting paragraph is extracted from the *Manchester Guardian* of the 30th ult.: "It is announced that the American Car and Foundry Company have acquired a site in Trafford Park for the purpose of erecting large works for the manufacture of railway wagons and carriages. This company already possess 15 large works in the United States, and their daily 'output' is more than 300 wagons and carriages. They have just undertaken a contract for the supply of the railway carriages for the Baker-street and Waterloo Underground Railway in London. All these carriages will be built and finished at the new establishment in Trafford Park. The only portion of the work which will be imported will be the steelwork, which will be received in a finished state. The remainder of the work will be done in England, and will necessitate the employment of local labour to the extent of £15,000 to £20,000. Although the land at Trafford Park was only acquired yesterday from the Trafford Park Estates, Limited, the company expect to have the workshops erected and the necessary equipment installed and to commence delivering the finished carriages early in March. We believe that the company were pressed to establish their works in the South of England, but that they preferred to come to Manchester. The exceptional advantages for speedy transport offered by the Ship Canal Company and the Trafford Park Estates, Limited (who have connections with all the important railways), coupled with the fact that the supply of the special kind of skilled labour which will be needed is larger in Lancashire than elsewhere, have doubtless weighed with the company in arriving at this decision. The works, which are about to be erected immediately, are only of a temporary character, but it is expected that the further railway contracts which the company are likely to obtain in this country will result in the building of extensive permanent works upon the same site in the near future."

London United Tramways Co.—In an interview the other day Mr. Clifton Robinson stated that a start will be made early next year with the extensive scheme of tramways throughout Kingston, Surbiton, the Dittons, Malden, and Wimbledon, the area embracing 15 route miles. Starting from a physical junction with the existing tramways at Hampton Wick, the route about to be built traverses Kingston Bridge, and proceeds the whole length of Clarence-street to its junction with Eden-street. At this point a line will branch off, and pass down Eden-street, St. James's-road, Penrhyn-road, Surbiton-road, and Claremont-road to Surbiton Station. Here there will be another junction, one line running *via* Victoria-terrace, Brighton-road, and Portsmouth-road to Thames Ditton, and thence on to Bridge-road, East Molesey; while the other line runs up Victoria-road past St.

Digitized by Google

Mark's Church, along Ewell-road to Tolworth, and *via* Ditton-road, Hook-road, and Southborough to the North Star at Hook. From the junction of Clarence-street and Eden-street, Kingston, one line will go the whole length of Richmond-road to the borough boundary at Ham, and a branch will run along King's-road up to Richmond Park gates. Another line will run up to the George and Dragon, Kingston-hill, and at Cambridge-road there will be a branch leading to New Malden, and thence *via* Burlington-road and a new road to be constructed to Raynes Park, and along Worple-road into Wimbledon. There is a terminus at the foot of Wimbledon Hill, but the line will cross the railway bridge, and run on through South Wimbledon to the terminus of the London County Council tramways at Tooting. It is understood that arrangements have been come to with the Surrey and Middlesex County Councils for the widening of Kingston Bridge. Mr. Robinson treated the agitation concerning the noise of the tramways humorously. Half a dozen of the authorities have declined to join the movement, but the company will endeavour to remove any reasonable cause of complaint.

London County Council.—At Tuesday's meeting the Council approved the Tramways Bill, which provides for carrying the system over the bridges and along the Embankment, and other smaller works to which we have already referred. The Highways Committee recommended that advances be made to Messrs. John Musgrave and Sons, Limited, notwithstanding the strict terms of the contract, as considerable progress has been made with the erection of the four 5,000-h.p. steam-engines at the Greenwich power station, for which the total order amounts to £96,713. They also recommended that expenditure on capital account not exceeding £2,250 be sanctioned for the provision of brick compartments for the switchgear at the same station, the contractors for this work being Messrs. H. Lovatt, Limited. For the reasons given in our issue of Oct. 28, the committee reiterated their recommendation that the proposal to supply seats for motormen and conductors be rejected. The committee are prepared, however, to arrange for shorter periods of duty. A correspondent to the *Times* states that the roadway along the Embankment is in a very unstable condition owing to the principles of Macadam having been disregarded by the use of irregular-sized stones. At last night's meeting of the City Corporation Alderman Sir John Bell presented a petition from the President and Court of Governors of Sion College against the proposal to run tramways along the Embankment. The receipts from April 1 to Nov. 19 totalled £429,634, against £337,462 last year. The Camberwell Borough Council have decided to urge the County Council to proceed with the construction of the authorised tramway lines in the district by local labour. Preparations are being made for the construction of the Dulwich tramways, the housebreakers being actively at work on Denmark-hill. The Stepney Borough Council have decided, in regard to certain lines, to oppose the Council's Bill for leave to dispense with the sanction of the local authorities to the use of the overhead system.

Pietermaritzburg.—The Corporation electric tramways were opened on the 2nd ult. in the presence of a large and representative company, which included the Mayor and Mayoress, numerous councillors, Government officials, Mr. R. W. Weightman (telegraphs engineer), the borough engineer (Mr. F. Walton Jameson), the tramways manager (Mr. P. Finlayson), the borough electrical engineer (Mr. Skidmore Ashby), and members of the power station staff. The Government engineer, Mr. Bosman, had given his approval earlier in the day. After an inspection of the power plant the party proceeded to the switchboard room, where the duty of turning on the current was performed by the daughter of Councillor C. W. B. Scott, chairman of the Tramways Committee. Satisfactory trials were then run on three cars, and the service was opened to the public. At the luncheon which followed, the chairman of the Tramways Committee referred to the efforts of the borough electrical engineer (Mr. Finlayson) and the borough engineer (Mr. Jameson), who had persevered with the scheme in the face of difficulties, such as the South African War and public apathy in the earlier history of the undertaking. Mr. Finlayson, in the course of his reply, expressed great confidence in the possibilities of the scheme, and recommended the provision of such attractions as bands at the Botanical Gardens and other places, which he thought would prove a valuable factor in enlarging the traffic. He deprecated premature reduction of fares, and quoted the opinion of Mr. John Young, late manager of the Glasgow tramways, that overlapping stages were a mistake. He also paid a tribute to the capabilities of his staff. Subsequently Sir George Sutton, the premier of Natal, pronounced his benediction on the undertaking. The system extends over some seven miles, and the total cost approximates £105,000, a large proportion of which was raised in this country. The Botanical Gardens and Scottsville sections are not quite complete, but are expected to be ready in the course of a few weeks. Extensive patronage has been accorded to the cars.

Aberdeen.—It is proposed to effect certain modifications of the tramway service during the winter, but these will not be of a very extensive character. Mr. Bell, the electrical engineer, reported to the Tramway Committee on Tuesday upon the accident which occurred on Friday last in Castle-street, when one of the live wires was broken and fell, entailing considerable danger to those who were on the street in the vicinity at the time. Mr. Bell pointed out that the accident was due to the negligence of one of the Suburban car conductors. The committee agreed to instruct Mr. Bell to send to the secretary of the Aberdeen Suburban Tramways Company a statement drawing attention to the matter, so that every care might be taken in future to prevent accidents of a similar character. Mr. Bell submitted a report as to the necessity of having a motorcar to be jointly used by the tramway, lighting, and electric departments for getting speedily to any place in the event of an accident occurring, as thereby life might be saved or danger to citizens obviated. It was remitted to the conveners of the three departments to enquire into the proposal. The committee agreed that a new system of indicating the destinations of cars, similar to that in operation at Manchester, should be adopted. Instead of having the destination painted on the cars, slipboards, with the names of the places, will be attached to the ends and sides of the cars, rendering them interchangeable. The dispute between the Corporation and the Great North of Scotland Railway Company, to which we referred in our issue of the 11th ult., came before Lord Pearson last week. The purpose of the application was to obtain interdict against the respondents making or maintaining in Union-street and Bridge-street a tramway passing place, junction, or such work, without the consent of the complainers, at a space less than 9ft. 6in. from the outside of the foot pavement opposite complainers' property of the Palace-buildings, as said pavement existed on Aug. 19 last and before proceedings by the respondents. An injunction was also sought restraining the Corporation from making alterations to Union-street or Bridge-street so as to diminish the width of the pavement opposite the complainers' property in these streets. The complainers referred to the negotiations in 1903 regarding the respondents' application for a provisional order to make and maintain certain lines of tramway in Aberdeen. After much negotiation the complainers agreed to withdraw their opposition to the order which was accordingly obtained, but upon certain terms, and a clause was inserted on the assumption of the permanency of the foot pavement of the width then existing. On May 11 the burgh surveyor wrote to the respondents' general manager with a plan showing a proposed additional junction between the tramway as authorised in Bridge-street and the existing tramways in Union-street. The nearest rail to the foot pavement at complainers' property was shown as only 9in. off, and showing a proposed rounding off and narrowing of the foot pavement at the junction to the extent of 6ft. The complainers wrote that they could not see their way to agree to this. On July 30 notice of application to the Board of Trade for consent to this junction appeared in the newspapers, and the complainers lodged representations strongly objecting to the proposals, but while this was before the Board of Trade the respondents' workmen, during the night of Aug. 19, curtailed the foot pavements, and narrowed them to the extent of about 7ft. 6in. width at the corner. The Board of Trade declined the company's application for a prohibition of the junction. The Corporation denied infringement of the company's rights, and contended that they had acted within their powers and with the consent of the Board of Trade. They do not project any further alterations to the pavement. Lord Pearson refused an interim injunction, and the case will in due course go to the Court of Session.

LIGHTING AND GENERAL.

Plean (Stirling).—The church of Plean has just been lighted by electricity.

Bethnal Green.—The Borough Council's electric lighting scheme is estimated to cost £80,000.

Islington.—Mains are to be extended, at a cost of £220, to meet recent applications for current.

Retford.—The Traders' Association has decided to memorialise the Corporation against the proposed electric lighting scheme.

Burgess Hill.—It is expected that a move will be made shortly with regard to the Council's electric lighting provisional order.

Boston.—An enquiry has been held into the application of the Town Council for sanction to borrow £20,000 for electric lighting purposes.

Sales of Plant.—Particulars of sales of various plant by the county borough of West Ham, the Western Electric Company, and others will be found in another column.

Newport (Mon.).—The electrical power service was suspended for an hour at mid-day on Tuesday owing to an obstruction in the water-meter at the Corporation-road works.

Goole.—The Board of Trade have decided to defer the consideration of the question of revoking the Urban District Council's electric lighting order for one year from Dec. 31 next.

Maidenhead.—An enquiry has been held into the Town Council's application for a loan of £7,000 for purposes of electric lighting, including extensions to Bray, Maidenhead Court, and Taplow.

Carnarvon.—The laying of the cables has now been practically completed, and the construction of the building at Balaclava is well in progress. It is hoped that the whole work will be completed by Christmas.

Haywards Heath.—The Haywards Heath Electric Supply Company have notified that they do not intend applying for a provisional order this year, but the Urban District Council will apply for an order themselves.

Stock Exchange. — The Stock Exchange Committee have ordered the Calcutta Tramways Company's further issue of 2,732 ordinary shares of £5 each, fully paid, Nos. 102,269 to 105,000, to be quoted in the official list.

Ormskirk.—The District Council have been informed by the Local Government Board that, notwithstanding the objections of the Council, the Board would issue an order authorising the Guardians to proceed with the electric lighting works at the workhouse.

Change of Address.—The registered office of the Newcastle-upon-Tyne Electric Supply Company, Limited, at Newcastle, has been removed from 50, New Bridge-street to Royal Exchange-buildings (situate at the corner of Grey-street and Hood-street).

Torquay.—To give employment to men in need of work, the Local Government Board have been asked to provisionally sanction the expenditure forthwith of £10,000 on account of the loan of £42,000 for the excavations, etc., of the new electric lighting works.

Huddersfield.—At the last meeting of the Chamber of Commerce a discussion arose on alleged defects of the local telephone service, and it

Digitized by Google

was decided to approach the National Telephone Company and also to communicate with Sir James Woodhouse and Sir Albert Rollit in the matter.

Dover.—The Electricity Committee have decided to adopt prepay ment meters, and in inviting applications state that for every 6d. placed in the slot sufficient energy will be obtained to light an 8 c.p. lamp for about 32 hours, or a 16-c.p. lamp for 16 hours. There is no charge for meter rent.

Southall-Norwood.—The Urban District Council are applying for an electric lighting provisional order because a private company is applying for powers. At the last meeting it was distinctly stated that the action of the Council was only in defence of the ratepayers, and not against the gas company.

Electrical Goods for Australia.—We are informed that Mr. O. L. Remington, general manager of Messrs. Wm. McLean and Co., of Melbourne, will be at the Hotel Cecil after Dec. 3 for the purpose of arranging for the representation in Australia of new lines of electrical goods and appliances. Mr. Remington also offers to reply to any manufacturer desiring information on the Australian electrical situation.

Gravesend.—The following committees have been appointed: Electric—The Mayor; Aldermen Russell and Wood; Councillors Sandford, Berkowitz, Rhodes, Davies, Enfield (chairman), Naylor, Archer, Prevost, Cosh, Byrne, Tolhurst, Schultz and Goldsmith. Paving, Lighting and Works, and Tramways—The Mayor; Aldermen Russell, Fletcher, and Cooper; Councillors Sandford (chairman), Berkowitz Davis, Enfield, Walter, Archer, Prevost, Cosh, Byrne, Tolhurst, Schult, and Goldsmith.

Portsmouth.—The Portsmouth municipal telephone exchange has obtained the County Council's consent to the erection of a line of telephone poles on the main road between Havant and Rowlands Castle. We understand that the Corporation are experimenting with four arc lamps of a new type. The lamps will be of between 800 c.p. and 1,000 c.p., and will cost £10 per annum apiece, as compared with the present cost of £18 per annum per lamp. The Roads and Works Committee propose to erect one of these lamps each in Portsmouth, Southsea, Landport, and Copnor.

Middlesbrough.—Messrs. Pease's Tubular Construction Syndicate, of Darlington, have been awarded the contract for the construction of a large electrical power station at Messrs. Bell Bros' steelworks at Middlesbrough, which will be entirely composed of patent steel frame plates and galvanised sheets on a foundation of concrete. The power plant, which will be one of the largest in any of the industrial establishments in the United Kingdom, will consist of three high-speed direct-coupled engines and generators, and a combined horizontal engine and dynamo, giving 1,250 i.h.p. The plant will also supply power to the works of Messrs. Dorman, Long, and Co., Limited.

Wolverhampton.—We understand that the new plant which has lately been laid down at the electrical generating station of the Corporation, is working very satisfactorily. This new machinery takes up about half the space of that which it has supplanted, but supplies much more power. The machinery which was laid down about the year 1896 consisted of horizontal rope-driven sets, which generated at a pressure of 2,000 volts. About 1899 the system of supply was changed, the low-tension, three-wire system at 500 volts being substituted. The engine-room, which formerly contained 1,000 h.p., now contains 4,500 h.p., and there is still room left for another 4,000 or 5,000, which may eventually save a large capital expenditure in building.

Mercury Vapour Lamps.—A company has now been formed to work the United Kingdom patents of the Bastian and Salisbury mercury vapour lamp, and Messrs. Rumney and Rumney, 39, Victoria-street, Westminster, have been appointed sole agents. We are informed that the delay which has occurred in putting the lamp on the market is owing to the many improvements that have been made since it was first shown, and that the lamp now designed is a self-contained one, consuming from ·25 to ·3 of an ampere at 200 to 250 volts. The candle-power is, owing to the colour, very difficult to determine accurately. It is estimated at not less than from 120 to 160. The lamp at present designed is only suitable for direct current but the inventors fully expect within a short time to have an alternating-current lamp ready.

The Recent Gale.—Although considerable damage was done to telephone and telegraph wires in some parts of the country, notably at Newcastle, it is satisfactory to know that in a very little time the Post Office authorities will be able to look with complacency on the fiercest storms that may rage. The underground system to Birmingham, which was opened more than two years ago, has worked very smoothly and well. The cables have also been completed as far as Warrington, and the system has been in working order for some time. Subsidiary cables are also working east and west of that town. From Warrington to Carlisle, a distance of 120 miles, the cables will soon be completed. The system from Warrington to Carlisle, it is hoped, will be ready for opening early in the spring, and then an extension of the system will be pushed on to Edinburgh and Glasgow, and subsequently, in all probability, further north.

London Gazette.—The partnership between Walter John Perry and Henry Arthur Aylett, carrying on business as electrical mechanical engineers at 257, Fulham-road and 44, Pelham-street, Chelsea, has been dissolved by mutual consent. The last day for receiving proofs in the estate of Charles Manners Downie, electrical engineer, 4, Bloomsbury-street, London, is Dec. 12. George Stapylton Barnes, late senior official receiver and liquidator, has been released from Nov. 21 in the matter of the Electric Railways Company, Limited. A receiving order has been made out on creditors' petition in the estate of William Watson and George Hautingdon, electricians, 83, Battersea-rise, Bond-street, London. The first meeting will be held on Dec. 9, at 2.30 p.m., at Bankruptcy-buildings, Carey-street, London. A receiving order has been made out on debtor's petition in the estate of Harry Cooke, electrical engineer, 102, Bucclench-road, Normacot, Longton.

Leigh.—An enquiry has been held into the application of the Corporation for sanction to borrow £16,115 for the purpose of extending the electricity works. The first installation at the electricity works was completed in February, 1899, and the loss on the working up to Nov. 9 of that year was £338; between Nov. 9, 1899, and March 31, 1900, the deficit was £247; and for the year ending March 31, 1901, the loss amounted to £101. Since then there have been profits made every year, that to March, 1902, being £80; to March, 1903, £263; and to March, 1904, £336. The total profits since the opening of the works, therefore, have been £681 and the total losses £687, so that the net loss has been only £6. This, said the town clerk yesterday, was a very good record considering the character of the works. There are at present 164 light and 87 power consumers, and the works are short of plant. The number of units sold has increased from 76,998 in 1899 to 460,305 this year.

Erith.—Messrs. Hawtayne and Zeden, the consulting engineers, have reported the inspection by them of the work being carried out by Messrs. Yates and Thom, Sir Hiram Maxim Electrical and Engineering Company, and the British Westinghouse Electric and Manufacturing Company, Limited, and found the same proceeding in a satisfactory manner. The Electricity Committee have further considered the application of Callender's Cable and Construction Company, Limited, for an additional supply of electric energy to their works, and have offered to enter into an agreement with the company, for the period of three years from date of acceptance of the offer, in lieu of the existing agreement, upon the following terms—viz.: to supply the whole of their demand upon a rebate system at the rate of 6d. per unit for the first hour's use per day of the maximum demand, and 1½d. per unit for all additional units, subject to the following discounts—25,000 and under 50,000 units per quarter, 9 per cent.; 100,000 units and over per quarter, 18 per cent., provided that the discounts shall only be allowed upon payment of the account within one month from the date of rendering the same. The committe recommend that the above tariff be adopted for all consumers o 100,000 units and over per annum.

Private Institutions.—Extensive additions and alterations have lately been made in the electric lighting arrangements at Culford Hall, the residence of the Right Hon. Earl Cadogan, K.G. Under the direction of Mr. R. S. Williams, M.E.I., the mansion has been extensively rewired, and at the generating station great improvements have been made. The engines have been separated from the boilers and placed in an adjoining room. A larger and more powerful boiler has been added to the plant, and a compound cylinder engine has been fitted up in the engine-room. Mr. L. A. Waterfield has also a recent installation at Dunstable. The engine, dynamo, switchboard, and accumulators have been installed in buildings some little distance from his house, current being taken thereto by lead-covered underground cables. The plant consists of a 7-h.p. Crossley gas-engine, driving by means of a long belt a Holmes Castle dynamo capable of running 140 8-c.p. lamps, or, in conjunction with the cells, 240 such lamps. There is a switchboard of three panels in black and white marble, with Nalder volt and ampere meters, an automatic charging switch, etc. The accumulators are located on the floor above, and are of E.P.S. Company's make, "K" type, and large enough to run all the lamps in the house for four or five hours. The contractors were Messrs. Garrett Bros. and Co., of Dunstable and Northampton.

Bermondsey.—At the last meeting of the Borough Council Councillor Vezey, chairman of the Electric Lighting Committee, in presenting the terms upon which it was proposed to supply electrical power and light to the Surrey Commercial Dock Company, said the tariffs were based upon the consumer's maximum demand and the number of hours per day the electricity is being used. If the electricity was used continually during the day the charge per unit is considerably reduced as compared with the charge made for a small day supply, as the standing charges of the Council's plant were the same practically whether the plant is working or at a standstill. The Dock Company were prepared to enter into an agreement for five years, with option of renewal for a second five years, at the following charges: For power, 2d. per unit up to 10,000 units per annum; 1¾d. for each unit beyond 10,000 and up to 20,000 per annum; 1½d. for each unit in excess of 20,000 per annum. If the consumption exceeds 50,000 per annum, the first 50,000 will be charged at 1½d. per unit; from 50,000 to 100,000, 1¼d. per unit; and all current in excess of 100,000 units at 1d. per unit. For lighting, 3½d per unit; any excess to be added to power consumption and charged accordingly. He moved that an agreement be entered into with the company upon these terms. The terms of the supply were fixed by the Council on Oct. 6, 1903, and those terms were adopted by the committee as the basis of a sliding scale upon which this agreement was based. After discussion the matter was again adjourned.

Electric Lighting Audit Regulations.—The following letter has been addressed by the London County Council to the Camberwell Borough Council: "The Highways Committee of the Council have given very careful consideration to the question raised in your letter of June 18, 1903, on the subject of competing electric lighting services in the borough of Camberwell, and to the points which arise in connection therewith. The committee have had the matter before them from time to time in connection with the general question of the electric lighting supply in London, and they have not, therefore, been in a position to reply before, at length, to the letter of the Borough Council. In connection, however, with the question of the audit of accounts the committee have instructed me to submit certain observations. With reference to the refusal of the Board of Trade auditor to hear the Camberwell Metropolitan Borough Council on the audit of accounts of the County of London Electric Supply Company, I am to suggest, for the consideration of the Camberwell Metropolitan Borough Council, that Section 8 of the company's order might be construed as

Digitized by Google

enabling the Board of Trade to direct the auditor to take into account the circumstances of the company and to allocate the capital expended between areas of the various local authorities in which the company is operating, and to prescribe that any party interested should be allowed to appear and be heard before the auditor. In this connection the committee would suggest that the Borough Council might consider the question of applying to the Board of Trade to make regulations to meet this point. The committee feel that the Council could not, with advantage, make representation to the Board of Trade on the question of the refusal of the Board to grant a competing order in Camberwell."

Southend.—An enquiry has been held into the application of the Town Council for sanction to borrow £56,000 for electric lighting purposes. The town clerk (Mr. W. H. Snow) and the electrical engineer (Mr. W. E. J. Heenan) gave evidence. The Town Clerk said the loan was required for extensions of the boiler-house and engine-house at the electricity generating station and for increasing the plant by the provision of four boilers, three dynamos, and an economiser, in accordance with the electrical engineer's particulars. The Council also wished to borrow money for the extension of the electric lighting mains through 53 additional streets as occasion might require. The engineer had told them that for present requirements they ought to have one additional dynamo and two boilers. The whole of the money would have to be expended within three years. The demand for electric lighting was increasing rapidly, and the application was made so that they might not keep consumers waiting. At the time of the application for the last loan for electric lighting in September last year the number of lamps connected with the mains were 27,800, and in October of the present year 42,284, giving an increase in a year of 14,484 8-c.p. lamps. The total capacity of the present generating plant was 1,125 kw., but on Sept. 24 the lighting load had reached 534 kw. and the traction load 330 kw., making a total of 864 kw. This left only a margin of 261 kw., reckoning upon the present demand, and the demand was increasing steadily. If one of the 350-kw. dynamos became disabled, they would have to shut down the works because they had not enough stand-by. For the financial year ending March 31 last the net profit was £358. 14s. 2d., but it was only since October, 1902, that they had been able to give a continuous supply. The Electrical Engineer stated that one of the items was an amount of £2,400, which would provide for 300 lamps at £8 each to be used for purposes of street-lighting.

Edmonton.—The District Council held a special meeting on Thursday night, Nov. 24, to consider the offers of the North Metropolitan Electric Power Supply Company, the Industrial Engineering Company, Foot and Milne, Limited, and the National Construction Company, Limited. Mr. Hawes (of the firm of Hammond and Son, consulting engineers) was present, and made an exhaustive report on the offers. He explained that that from the North Metropolitan Company was practically an offer to take over the Council's powers and work the undertaking on their own lines, the Council not to have the privilege of purchasing it until after the expiration of 26 years. The current would be supplied from one of the company's large power stations to a transforming station in the district, and would be distributed on the three-phase system. That might be a disadvantage to the Council when they acquired the undertaking, because the district was eminently suitable for a direct-current supply. The company limited the mains at the start to the compulsory area, whereas he did not think the Council would do so if they established the works. The rates of charges quoted by the company were quite reasonable both for lighting and power, and also for public lighting, provided that the latter included the carboning, trimming, and maintenance of public lamps. The company gave the Council the option of considering the revision of the tariff every seven years. They were willing to divide the net profits after taking 5 per cent. upon the whole of the capital involved, which he supposed would mean after also paying directors' fees. The other three offers were of a different character, being for the execution and maintenance of works. Foot and Milne, Limited, offered to maintain the undertaking for 25 years, and to give the Council certain conditions of purchase up to 15 years. After six months' notice they were prepared to transfer the undertaking to the Council upon the Council paying any loss they might sustain plus 4 per cent. interest, but less 4 per cent. on any surplus profits which they might make beyond the amount of the interest and sinking fund, which they would have to pay to the Council. They did not state the prices for current, which was a bad fault. The Industrial Engineering Company's offer was conditional upon the Council laying down gas-driven dynamos, and upon all the plant being manufactured by themselves. They further agreed to work the undertaking for only five years, and under their terms, if the Council decided to take it over within that period, they would practically have to guarantee them a gross profit of nearly 10 per cent., which would be an extraordinary yield. The offer from the National Electric Construction Company deserved the Council's consideration. They were prepared to tender for the complete works to the Council's own specification, and they required a bonus of 5 per cent. on the net price of the tender. They agreed to maintain for 25 years, and they gave the Council the option of purchase at seven, ten, or fifteen years—at seven years on the basis of the payment of a bonus of 12 per cent., at 10 years of 7½ per cent., and at 15 years of the exact amount of the capital expended. They agreed to divide all the profits beyond 3 per cent. if the option to take over at seven or ten years was not exercised. Their prices were distinctly favourable—flat rate, 5d. per unit; maximum demand rate, 7d. per unit for the first hour and 2d. afterwards. For power they quoted a sliding scale. Mr. Hawes also dealt with an offer received from the Metropolitan Company to supply in bulk. Their prices worked out at about 2·37d. per unit for maximum demand supply for 200 hours, and 2d. per unit for regular supply every day of the year for 300 hours. His firm did not see how the Council could afford to pay for a bulk supply, high-pressure tariff, at a price exceeding 1·14d. per unit. Failing an offer approaching that figure the Council should devote their attention to the tender of the North Metropolitan Company to take over the Council's powers, or to that of the National Electric Construction Company. A long discussion ensued upon a motion that the former of these two offers should be accepted. An amendment was brought forward that a contract should be entered into with the latter company. Several members reflected upon the methods of the North Metropolitan Company. The meeting was in the end adjourned under the standing orders without the amendment having been voted upon.

Stoke Newington.—At a special meeting of the Council on Tuesday the following report and recommendations of the Electric Lighting Committee were adopted: "The publication in the month of June last of the committee's report of the 16th of that month, led to the reopening of negotiations which have resulted in the modification of the scheme which the committee previously submitted to the Council, and the committee now submits that scheme so modified for the approval of, and adoption by, the Council. The main outlines of the scheme remain as at the date of the committee's report of June 16, 1904, but certain modifications are suggested as hereinafter detailed. The chief modification which the committee has sought and obtained is the introduction of a safeguard against any possible loss by the Council during the early years of the working of the undertaking, a loss which the committee in its last report estimated as possibly involving a charge on the rates of about 1d. in the £. It has now been arranged that during the first three years of the Council's undertaking, and for such additional number of years as the Council shall think fit, the company supplying the energy shall be paid for such energy the amount of the net revenue which the Council may derive from the undertaking, and that any loss which may occur shall be borne by the company. Whenever the Council thinks fit this arrangement may be determined, by not less than six months' previous notice, on March 31, 1909, or any subsequent March 31. Upon such determination the scheme outlined in the committee's report of June 16, 1904, will come into operation with the following modifications: (1) It is left open to the Council to make an arrangement with the Islington Council for the supply of energy at or near the junction of Blackstock and Seven Sisters roads to enable this Council to comply with an application recently received for the supply of such energy; and provisions are made for the continuance of any such arrangement with the Islington Council, similar to the provisions previously made respecting the Council's agreement with the Hackney Council. (2) The minimum period of 12 years mentioned in the former report as the period before the expiration of which the agreement there detailed could not be determined will now run from the determination of the system already explained as intended to apply to the early years of the undertaking. It is a part of the scheme that the Council's scale of charges shall be revised, so that instead of a uniform or flat rate of 5d. per unit for light, consumers shall pay on the maximum demand system at the rate of 7d. per unit for the first hour's daily use of the maximum demand in each quarter and 2d. per unit for all subsequent consumption; and that in place of the present 3d. per unit for power there shall be charged 5d. per unit for the first hour's daily use of the maximum demand and 1d. per unit for all subsequent consumption when the demand does not exceed 20 h.p., with the substitution of 4d. for 5d. when the demand does exceed 20 h.p. Present consumers, however, are to have the option of continuing at present rates. The charge for public lighting is to be 1·45d. per unit for lamps alight during all-night hours, and 1·85d. per unit for those alight during half-night hours. So far as regards the nine arc lamps in High-street and Stoke Newington-road, the total charge is not to exceed the £20 per lamp now payable to the Hackney Council. The scheme outlined in the committee's report of June 16, 1904, is to be proceeded with. The works are to be carried out to the reasonable satisfaction of the company, and the agreement provides for such extension as the Council and the company may agree, or as the Council may be lawfully called upon to undertake. Provision is made for the reference to arbitration of disagreements on these points. The company is to bear as part of the expenses of the undertaking the interest and sinking fund or repayment of loan upon the capital outlay involved by the scheme, including the £3,000 already raised, and if the London County Council should require a maintenance or reserve fund for repairs or renewals, that also is to be similarly borne; but if any part of the last-mentioned fund remain at the termination of the period during which the company is to take the profits and bear the losses, the amount so remaining is to be repaid to the company. When the yearly receipts for energy supplied for lighting exceed 4d. per unit for the total number of units supplied during the year, the excess is to belong to the Council, and similarly any surplus over 3d. per unit for the total number of units supplied during the year for power is to go to the Council. The agreement submitted by the committee with its report on June 16 last has been revised in accordance with the foregoing provisions, and the revised agreement is now submitted herewith. Since June 16 the company has commenced its supply of electrical energy for the purposes of the running of the trams connecting Finsbury Park with Tottenham and Wood Green, and the tramcars have been running for some time past. In lieu of the recommendations in its report of June 16, 1904, the committee recommends: (1) the adoption and sealing of the agreement with the North Metropolitan Electric Power Supply Company submitted herewith; (2) the adoption and carrying into effect of the scheme outlined in this report, including the acquisition of the necessary sites, the erection and equipment of the necessary station, and the laying of cables in Church-street, Lordship-road, Lordship-park, Manor-road, Woodberry Down, and Seven Sisters-road; (3) the reference to the General Purposes Committee of the acquisition of the sites for the meter and transforming stations; (4) the immediate appointment of the Standing Electric Lighting Committee, and the reference to it of all the foregoing works other than the acquisition of the said sites. At the next meeting of the Council it will be proposed that the agreement be sealed.

PROVISIONAL PATENTS, 1904.

Nov. 21.

25243. Improvements in or relating to the "party line" system of telephones. Harry Benwell Stocks, 5, John Dalton-street, Manchester.

25248. Improvements in or in connection with electric ignition apparatus for internal-combustion engines. William Clapham Priestley and Benjamin Holroyd, 30, Park-row, Leeds.

25249. Improvements in electric switches for the ignition circuits of multiple-cylinder explosion motors. Ernest Talbot and David Môndey, Bank-buildings, George-street, Sheffield.

25265. Improvements in or relating to the manufacture of storage battery or accumulator electrodes. Alfred Julius Boult, 111, Hatton-garden, London. (Accumulatoren und Electricitäts- werke Actien-Gesellschaft vormals W. A. Boese und Co., Germany.)

25276. Improvements in vapour electric lamps, rectifiers, and the like. The British Thomson-Houston Company, Limited, 83 Cannon-street, London. (The General Electric Company, United States.)

25282. Improved electrode for apparatus producing radiant electrical energy. Siemens und Halske Aktien-Gesellschaft, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Nov. 24 1903, being date of application in Germany.) (Complete specification.)

Nov. 22.

25329. Improvements in electrical measuring instruments. William Clark Fisher, 24, Albany-road, West Ealing, W.

25331. Improvements in treating the contents of electrolytic cells. James Hargreaves, May Villa, Farnsworth-in-Widnes, Lancs.

25370. Improvements in telephony. John Hodgson Lee and Arthur Emilio Roles Bottone, 3, Arlington-street, London.

25376. Improvements in or relating to electric batteries. Heinrich Csanyi, Eugén Klupathy, and Gabriel von Bárczay, 111, Hatton-garden, London.

25378. Improvements relating to electric air-gap condensers for use with high-frequency currents. Henry Harris Lake, 7, Southampton-buildings, Chancery-lane. London. (The Electro-Radiation Company, United States.)

25382. Improvements relating to rotary spark-gap apparatus for use with high-frequency currents. Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (The Electro-Radiation Company, United States.)

25386. Improvements in single-phase commutation motors. Thorsten von Zweigbergk, 18, Southampton-buildings, Chancery-lane, London.

25466. Improved method of amplifying variations of energy in electric circuits. Peter Cooper Hewitt, Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London.

Nov. 23.

25458. Improvement in electromagnetic circuit breakers. Veritys, Limited, and Arthur Edgar Gott, 11, Burlington-chambers, New-street, Birmingham

25463. Improvements in and connected with brush-holders for dynamo-electric machines and electric motors. Ernest Sherwood Woollard Moore and Sidney Bourne, Prince's-chambers, Wolverhampton.

25492. Trolley for electric cars. Lewis Mitchell McBride, 81, High Holborn, London.

25498. Improvements in the construction and attachment of gear wheels for electric and similar high-speed cars. Alfred Wiseman, Prudential-buildings, Corporation-street, Birmingham.

25504. Oscillating magneto sparking plug. Richard Howard Derry, 3, Shenley-road, Camberwell, London.

25519. Improvements in electric incandescent candle lamps. Frederick Charles Dafforn, 34, Sherborne-gardens, West Ealing, London. (Complete specification.)

25524. Improvements in electric lighting of railway carriages and the like. Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (John Denham, Cape Town.)

Nov. 24.

25592. Improvements in electric switches. Charles Ernest Hunter, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

25610. Improvements in or relating to wireless telegraphy. Franklin Wise Howorth, 46, Lincoln's inn-fields, London. (George Owen Squier, United States.)

25613. Improvements in trolley wheels for use on electric railways. Herbert John Haddan, 18, Buckingham-street, Strand, London. (Solomon W. Bates, United States.)

25620. Improvements in apparatus for controlling or/and supplying current for power and light on consumers' premises during certain periods. Alfred Mills Taylor, 77, Chancery-lane, London.

25625. Means for facilitating the control of accumulator cells. Henry Leitner, 4, South-street, Finsbury, London.

25630. Improvements in and relating to systems of control for electrically-operated doors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25631. Improvements in electric circuit breakers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25632. Improvements in and relating to electric meters. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25633. Improvements in reverse-current relays. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25634. Improvements in seals for vacuum tubes. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25635. Improvements in attachments for trolley poles. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25636. Improvements in and relating to electric power transmitting mechanism. The British Thomson-Houston Company, Limited, Hans Sigismund Meyer, and Bernard Hopps, 83, Cannon-street, London.

25637, 25638, 25639, 25640, 25641, 25642, 25643, 25644, 25645, 25646, and 25647. Improvements in or connected with space telegraphy. John Stone Stone, Norfolk House, Norfolk-street. Strand, London. (Dates applied for under Patents Act, 1901, Nov. 24 and 25, 1903, being dates of application in United States.) (Complete specification.)

Nov. 25.

25648. Improved electric glow lamp with combined reflector or shade. Walter Bidford Spurrier, Laurel Villa, Gibbs-road, Newport, Mon.

25682. Improvements in arc lighting lamps. Lorens Sigfrid Andersson, 65, Chancery-lane, London. (Date applied for under Patents Act, 1901, Nov. 30, 1903, being date of application in Sweden.) (Complete specification.)

25693. Improvements relating to insulated chairs for carrying electric current conducting rails. Walter Way, 27, Dalling-road, Hammersmith, London.

25708. Improvements in electric projecting lamps chiefly for enlarging and projecting lanterns. Leo Kamm, 27, Powell-street, Goswell-road, London.

25729. Improvements in and relating to dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25730. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Nov. 26.

25764. Improvements in electric motor controllers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25781. Improvements in or connected with electric ignition apparatus particularly applicable for explosion engines. Lewis Charles Ingram, Samuel Raphael Cohen, and Barnett Raphael Cohen, 33, Chancery-lane, London.

25784. Improvements in means for regulating electric circuits. Henry Leitner and Richard Norman Lucas, 4, South-street, Finsbury, London.

25786. Improved construction of appliances for producing electric light displays. Alexander Elis Dakhyl and Antonio Gallanti, 173, Fleet-street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 8, 1904.

1904.

1027. Electric light switches, electric bell pushes, and the like. Beldam.

1036. Accumulators or secondary batteries. Pescatore.

1044. Electrical contact maker for gas, oil, and all internal-combustion engines. Alltree.

2496. Apparatus for producing oscillatory electric currents. Hewitt. (Date applied for under International Convention, Feb. 9, 1903.)

4953. Apparatus for automatically interrupting an electric current. Aktiebolaget Svenska Elektriska Urfabriken. (Date applied for under International Convention, March 3, 1903.)

6972. Electrodes for arc lights. Gerard and Fiedler.

14136. Brush-holders for dynamo and other rotary electrical machines. Foot. (Date applied for under International Convention, June 24, 1903.)

17741. Alternating-current power-transmitting apparatus. Fairweather. (Arnold Magnetic Clutch Company.)

19125. Brush-holders for dynamo and other rotary electrical machines. Lamme. (Date applied for under International Convention, Sept. 16, 1903.)

20896. Manufacture of water jackets, casings, and the like by electrolytic means. Bosquet.

Digitized by Google

21463. Method for increasing the activity in electrode masses of badly-conductive metallic oxides or hydrates in accumulators with invariable electrolyte. Jungner. (Date applied for under International Convention, Oct. 31, 1903.)

21795. Dynamic-electric clutch or electromagnetic gearing. Von Lieben and Reisz.

21913. Manufacture of galvanic cells. Ziegenberg.

To be published Dec. 15.

1903.

25669. Electric conductors or cables. Brown.

25854. Suspenders for overhead electric conductors. British Thomson - Houston Company, Limited. (The General Electric Company.)

25970. Current collector for use in stud-contact systems of electric traction. Griffiths and Bedell.

26180. Electric fuses or cut-outs. Hepke, Diener, and Ascher.

28252. Electric lighting batton for theatrical and other purposes and method of preventing confusion of colours by lamps therein. Sunderland.

1904.

45. Electrically-controlled lifts. Richmond and Carey.

660. Electric alarm bells. Plato.

699. Electric stoves and heating and cooking apparatus. Bauer.

820. Electric switches and the like. British Thomson-Houston Company, Limited. (General Electric Company.)

1326. Electrical switches. Hope, Sugden, and Gardner.

1481. Alternating-current electric motors. British Thomson-Houston Company, Limited. (General Electric Company.)

1482. Alternating-current electric motors British Thomson-Houston Company, Limited. (General Electric Company.)

1483 Alternating-current motors. British Thomson-Houston Company, Limited. (General Electric Company.)

1625. Electric arc lamps. Gross.

1642 Electric switchboard. British Thomson-Houston Company, Limited, Wedmore, and Whitcher.

2676. Electric couplings for arc lamps and the like. Schaefer. (Bastians and Wehrmann.)

3328. Switches for electric lighting and heating. Lundberg and Lundberg.

3357. Rapid trembler for induction coil. Marks. (Guenet.)

6429. Elastic insulating clutches for electric dynamos and motors. Lake. (Risso.)

11168. Safety devices for protecting dynamo-electric machinery and the like against the excessive voltage occurring when they are switched in or out. Electricitäts Actien-Gesellschaft vorm. W. Lahmeyer und Co. (Date applied for under International Convention, June 27, 1903.)

15258. Electro-magnetic switch devices for telephone stations. Arnheim. (Rights under Patents, etc., Act, 1901, not granted.)

17672. Induction coils for medical and other purposes. Dymond. (Watson and Wheeler.)

18561. Live-rail protections for electric railways. Linkleter.

20000. Coils for electrical apparatus. Fortescue. (Date applied for under International Convention, Sept 30, 1903.)

20063. Process and furnace for subjecting solid materials to the action of the electric arc. Birkeland and Eyde. (Date applied for under International Convention, Sept. 19, 1903.)

20478. Telegraph systems. James. (Crehore.)

20531. Protectors or polishers for commutators, collector rings, and the like in electric machines. Boult. (Elektricitäts-Gesellschaft Zschockelt m. b. H.)

20689. Regulation or control of dynamo-electric machines and electric motors. Schneider.

22287. Electrical switches. Lundberg and Lundberg.

22536 Auxiliary appliance for the prevention of the occurrence of excess pressures on switching on and off electrical installations of high voltages, applicable also for testing purposes. Siemens Bros. and Co., Limited. (Siemens-Schuckertwerke G. m. b. H.)

23031. Fuse heads for electric blasting. Render.

NOTES.

Birmingham Electric Club.—This organisation, we are pleased to see, has so far taken root that the opening meet is to be held to-morrow night, when the president, Mr. J. J. Inniss, will deliver his inaugural address. We have received a copy of the proposal form for membership, the conditions of which seem reasonable. A member of the committee intimates that the main lines of the club are to be "the spread of electrical knowledge, and no class prejudice." Everything, the same gentleman remarks, points to a pronounced success.

McMillan Memorial Fund.—As the result of Mr. W. H. Patchell's appeal for contributions to this fund at the Institution's annual dinner last week, a total of about £160 was immediately collected, while some £16 more is promised. As the balance necessary to bring the fund up to the desired £2,000 is now only a matter of £60 or so, it has been decided to keep the appeal open for a few days longer. Seeing how nearly the fund approaches the contemplated figure, it would be particularly regrettable if it now failed to realise the complete sum.

Rapid Telegraphy.—A demonstration of the working of the Pollak-Virag apparatus for telegraphic transmission is to be held at the Carlton Hotel to-day. It is stated that 50,000 words an hour can be sent over the wires by this method. Since the conference at Paris in 1900 great progress has been made in the trials of the system, and it is now reported that all difficulties have been surmounted, and that the apparatus has been put into such simple form that any telegraphist can use it after a few days' practice. It is claimed that the invention will be of special advantage in connection with Press telegrams and private Press wires.

Northampton Institute.—As announced in our issue of the 18th ult., the prizes and certificates will be presented to-night by Lord Reay, at eight o'clock. This will be preceded by an organ recital. Afterwards a conversazione will be held, in connection with which a number of interesting features have been arranged, including a short lecture on "Electric Lighting—Past, Present, and Future," by Dr. C. V. Drysdale. The conversazione will be continued to-morrow from 6.30 to 11, when there will be two promenade concerts and an organ recital. Other attractions comprise demonstrations of various processes, exhibition of apparatus, and gymnastic displays.

New Publications.—"Fowler's Mechanical Engineer's Pocket Book for 1905" (Manchester: Scientific Publishing Company; leatherette and red edges 1s. 6d., leather and gilt edges 2s. 6d.).—"A Treatise on the Theory of Alternating Currents," by Alexander Russell (Cambridge University Press; London: C. J. Clay and Sons and H. K. Lewis).—"The A.B.C of the Differential Calculus," by W. D. Wansbrough (The Technical Publishing Company, Manchester; John Heywood, Manchester and London; and Simpkin, Marshall, and Co., London. 3s.). "The Practical Electrician's Pocket Book for 1905" (London: S. Rentell and Co., Limited).

The Royal Society of Edinburgh.—As already announced, the council of the Royal Society of Edinburgh have awarded the Gunning Victoria Jubilee prize for 1900-1904 to Sir James Dewar for his researches on the liquefaction of gases, extending over the last quarter of a century, and on the chemical and physical properties of substances at low temperature. In addition, the council have awarded the Keith prize for 1901-1903 to Sir William Turner for his memoir entitled "A Contribution to the Craniology of the People of Scotland" and for his "Contributions to the Craniology of the People of the Empire of India," Parts I., II.; the Makdougall-Brisbane prize for 1902-1904 to Mr. John Dougall, M.A., for his paper on "An Analytical Theory of the Equilibrium of an Isotropic Elastic Plate"; and the Neill prize for 1901-1904 to Prof. J. Graham Kerr, M.A., for his researches on Lepidosiren paradoxa.

Electro-Harmonic Society.—We are informed by Hon. Sec. Lane that at a meeting of the executive committee the growing practice amongst members of reserving chairs before the concerts commence, especially on "ladies' night," was discussed, and it was felt that the time had come for the introduction of some regulation on the matter. After careful consideration, the following regulation was unanimously adopted: "That chairs may only be reserved up to ten minutes to eight o'clock, after which time any vacant chairs may be occupied." The committee believe that the above rule will meet the general convenience, and they confidently rely upon the members to assist in its observance. As some few instances of smoking were observed in the hall at the last concert, the committee take this opportunity of earnestly requesting members to refrain from smoking in any part of the hall or gallery at the "ladies' night" concerts in future.

Windsor Castle.—Unlike her late Majesty, who entertained an aversion to electric lighting, King Edward greatly favours this form of illumination. It was installed at Marlborough House and at Sandringham a good many years ago, and since his accession he has had both Buckingham Palace and Windsor Castle lighted throughout by electricity, which is also utilised in various other ways. During the late reign there was a small generating plant under the north terrace at Windsor Castle, but that was removed, and the whole of the current required is now supplied by the local electric company, the lighting being regulated by an official within the Royal residence. There are many thousands of lamps fitted throughout the length and breadth of the Castle, the whole of which were in demand during the presence of the King and Queen and their Royal guests from Portugal. On the evenings of the concert and the dramatic performance the consumption of current exceeded all previous records.

The Tyranny of the Telephone.—Subscribers to the telephone in Paris are so impressed with their grievances that they have formed an association. They complain of defective staff organisation, inattention, and incivility. A meeting was held the other day at the Palais d'Orsay Hotel to claim justice in regard of their grievances, and to do justice to a banquet—it is not clear which was the paramount feature. The assembly was of a cosmopolitan order, including the Marquis de Montebello, who presided, a politician, journalists (male and female), and some actresses. One of the latter, Mdlle. Sylviac, who said some very emphatic things over the wires one day to one of the telephone girls, was introduced by the marquis as the Joan of Arc of the telephone for having raised the standard of revolt against defective organisation. The marquis pointed out that the agitation for a better telephone service had brought to the table men of clashing political opinions. He likewise cordially thanked the Press for having ventilated the grievances and backed the claims of the victims of the telephone. In every country, concluded the marquis, the telephone is a perfected invention save and except in France, and it was the duty of the subscribers to see that an amelioration in the service takes place. M. Marcel Sembat, a deputy, next spoke, expressing a hope that the telephone would be made a practical business aid, and not an instrument of irritation.

Entering the Profession.—In last week's issue of *T. P.'s Weekly* there appears an interesting article on "How to Become an Electrical Engineer," which is the sixth

Digitized by Google

article of the series entitled "Careers for Men and Women." We see no evidence, however, in the article before us that women are likely to invade in any number the profession of electrical engineering. The remarks on the making of the engineer, both as training in college or evening classes and in the workshop, are exceedingly well thought out, and the author is equally fair when he deals with the reward which an electrical engineer may expect after training. He puts the usual cost of a three years' technical college course at from £60 to £80, and the works premium at a maximum of £300 for three years. In return for this the high-class works manager or power supply engineer may receive as much as £1,500 a year. As the author naïvely puts it, however, "the average electrical man studies practical economics on £150 to £200 a year, while operatives will take anything from 25s. to 45s. per week. No one can determine the exact amount to be expected, for it depends largely on each man's energy and resource, and also upon those unexpected happenings which in every career determine whether the life-effort of a man will spell success or failure." The only criticism we have to make on the article is that no mention is made of the Central Technical College in Exhibition-road, which ranks, in our opinion, higher than any of the colleges and schools mentioned in the article.

Electric Driving in Cotton Mills.—The advantages of electricity for driving cotton mills have obtained recognition in Spain, where one of the largest proprietors (the Marquis of Larios) has decided to introduce it. His two spinning and weaving mills at Malaga are the biggest in the country, employing some 5,000 hands. Arrangements have lately been made by him for obtaining a supply of electric power from the Chorro Power Company, which has established a generating station in the celebrated Chorro Gorge, some 50 miles north of Malaga. The power is transmitted by three-phase current at a pressure of 25,000 volts to a sub-station in Malaga, where the pressure is reduced to 2,500 volts, part of the energy being supplied to the Malaga electric lighting station. A secondary receiving station is to be placed at each of the two mills, containing three-phase transformers for reducing the pressure from 2,500 to 400 volts for supplying the three-phase motors, which will be employed universally throughout the mills, the steam plant being entirely discarded. There will be 72 motors, varying in power from 3 h.p. to 150 h.p., and aggregating 2,500 h.p. It is anticipated that the use of electricity will result in a saving of over 20 per cent. in operating costs. The installation will be one of the largest and most complete of its kind, and the contract for the plant excited keen competition among the leading German, Austrian, and Swiss firms, so that Messrs. Mather and Platt, Limited, of Salford Ironworks, Manchester, have scored a gratifying success in obtaining the order. This success in a neutral territory is the more satisfactory because it has generally been assumed that British makers have not devoted so much attention to polyphase work as their Continental rivals.

Daily Consular Reports.—We have received from the Department of Commerce and Labour at Washington, U.S.A., a copy of the "Daily Consular Reports" for Nov. 16 this year. These reports are of great value to commerce in any country which does an export trade. For instance, in the report before us we find information as to the marketing of goods in Greece, Malta, the Netherlands, Russia, and Scandinavia. The figures given show not only the actual trade between the United States and the country in question, but also the various sub-divisions of goods actually exported. These figures enable the commercial man to see what the possibilities are in his particular line, and from written reports he gets some useful hints as to the way in which business is conducted in these countries. It is obviously absurd for a wholesale trader in England, for instance, to attempt to break down the trade customs in the country to which he is exporting. He will be much wiser if he increases his selling prices in order to meet the additional risks involved by these customs. For instance, speaking of Denmark, the report shows that three months' absolute credit on all foreign goods is granted in all foreign countries except the United States. The report goes on to say that there is a disposition on the part of German merchants to extend the credit beyond the usual three months. The U.S.A. consul at Copenhagen points out that the enforcement of the well-known rule of cash payment against bills of lading in New York is a great hindrance to the American export trade to Denmark in many lines of goods. There is no doubt that our large mercantile houses are well informed as to the best way in which business can be conducted in foreign countries, but some such system of consular reports issued more promptly would be of more use in this country to smaller firms commencing their export trade.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on Monday, Sir James Crichton-Browne, M.D., F.R.S., treasurer and vice-president, in the chair. Colonel C. W. Carr-Calthrop, Mr. Cecil Hanbury, Dr. E. Graham Little, Mr. Hugh Makins, and Mr. E Reinach were elected members. The following are the lecture arrangements at the Royal Institution before Easter: A Christmas course of lectures (experimentally illustrated and adapted to a juvenile auditory) on "Ancient and Modern Methods of Measuring Time," by Mr. Henry Cunynghame; Prof. L. C. Miall, Fullerian professor of physiology, R.I., six lectures on "Adaptation and History in the Structure and Life of Animals"; Prof. Karl Pearson, three lecture on "Some Recent Biometric Studies"; Prof. W. E. Dalby, two lectures on "Engineering"; Mr. A. H. Savage Landor, two lectures on "Exploration in the Philippines"; Mr. Churton Collins, two lectures on (1) "The Religion of Shakspere," (2) "The Philosophy and Significance of 'The Tempest'"; Prof. W. Schlich, two lectures on "Forestry in the British Empire"; Mr. J. J. H. Teall, two lectures on "Recent Work of the Geological Survey"; Prof. H. H. Turner, three lectures on "Recent Astronomical Progress"; Prof. R. Meldola, two lectures on "Synthetic Chemistry" (experimental); Sir Alexander Mackenzie, three lectures on the "Bohemian School of Music" (with musical illustrations); Mr. D. G. Hogarth, two lectures on "Archæology"; Prof. J. J. Thomson, three lectures on "Electrical Properties of Radioactive Substances": and the Right Hon. Lord Rayleigh, three lectures on "Some Controverted Questions of Optics." The Friday evening meetings will begin on Jan. 20, when a discourse will be delivered by Prof. Sir James Dewar on "New Low-Temperature Phenomena." Succeeding discourses will probably be given by Dr. E. A. Wilson, Mr. Cecil Smith, Mr. J. W. Gordon, Prof. H. Marshall Ward, Chevalier G. Marconi, Prof. J. J. Thomson, Sir Squire Bancroft, Prof. G. H. Bryan, Prof. J. Wright, Prof. J. C. Allbut, the Right Hon. Lord Rayleigh, and other gentlemen.

Metropolitan Railway.—This company, a considerable portion of whose system will be ready for electric traction in a very few weeks now, have decided to have carriages of two classes. They do not consider that any appreciable delay will result from this arrangement. This may be so if the public lend their co-operation by stationing themselves at the sections of the platforms devoted to the respective classes as indicated by the signboards;

Digitized by Google

unfortunately, they do not always do this. Two classes, however, cause much less delay than three, the effect of additional classes beyond two being to multiply, rather than merely to add to, the confusion. The Metropolitan Company's rolling-stock is of a sumptuous character and of the latest design. The cars are a little over 50ft. long, arranged with both transverse and longitudinal seats. The superior class non-smoking cars are upholstered in art-green moquette; the interior panels and mouldings and the decorative work are very attractive. The smoking cars of the higher class are similar in all respects save upholstery, which is carried out in green leather. The second-class cars all have buffalo hide seats, and the decorative work is less elaborate. Electrical heaters are supplied to all the carriages, which are brilliantly lighted by electricity. In the construction every provision has been made to ensure the fullest protection against fire. The floor is of steel, covered with a non-combustible cement; the roof is of asbestos; the sides (the outsides of which are painted and varnished to represent polished teak) are, like the frame of the seats, of steel; while the upholstery is inflammable. Each car is mounted on English manufactured pressed-steel four-wheel bogie trucks, and each of the axles in the case of the motorcars is driven by a separate iron-clad motor of 150 h.p. normal capacity. Having a motor-car at each end, every train of six carriages will carry eight electric motors. Each car will seat 49 passengers, and the train has a driver's compartment and a luggage compartment at one end and a covered-in platform at the other. The platform is fitted with a vestibule, having sliding doors of an entirely new design.

Personal.—Prof. H. S. Hele-Shaw, of the University of Liverpool, has resigned his position as head of the faculty of engineering, having accepted the post of senior and responsible professor of the new technical institute which it is proposed to establish in the Transvaal. Prof. Hele-Shaw went out to South Africa last year for the Colonial Office as organiser of technical education in the Transvaal, and it is upon his reports that the Government propose to set up the new institution in or near Johannesburg. The council of Liverpool University passed a resolution on Tuesday recording their appreciation of his valuable services to the university and to education generally, and congratulating him upon his election to such an important office. In 1876 the professor secured the Whitworth scholarship; two years later he obtained the Miller scholarship in the Institute of Civil Engineering, and he also took various other honours during his course at the University College of Bristol, where he became lecturer and afterwards professor. He went to Liverpool as the first professor of engineering at a time when there was no endowed chair and no laboratories, and commenced his duties with three students. To-day the university possesses a faculty in engineering, and one of the largest schools in the world. His appointment last year by the Colonial Secretary as organiser of technical education in the Transvaal placed him in the position of having held the first professorship of engineering in three separate institutions. During the time he has been in Liverpool, and previously, he has contributed upwards of 60 papers to all the scientific institutions, both in this country and abroad, and has been awarded such distinctions as the Watt gold medal, the Telford premium in the Institution of Civil Engineering, the gold medal of the Institution of Naval Architects, and numerous other medals and premiums for his scientific researches. He has also been awarded the honorary degree of doctor of laws at the University of St. Andrews, and the coveted honour of a fellowship of the Royal Society. Prof. Hele-Shaw will leave England at the beginning of the new year, and we wish him every success in his new sphere.

Tramways and Light Railways Association.—The fact of the Institution dinner falling on the same night as Mr. Sellon's paper on "Running Powers," with which we deal fully in another part of this issue, reflected itself in the limited attendance at the Society of Arts rooms. The audience comprised two or three visitors not usually seen at these meetings, including a barrister and an alderman, both of whom spoke. Though the discussion was only participated in by four speakers, it ran into an hour and a half, with Mr. Sellon's reply. The keynote of the discussion was whether inter-running should be by compulsory powers—that is to say, whether there should be a general enactment providing for reference to some tribunal if private negotiations failed, or whether everything should be left to voluntary arrangement. There was considerable diversity of opinion under this head, which extended to those belonging to the same class of interest. Thus, while the president, a corporation man, was opposed to compulsory powers, the representatives of the West Ham Corporation considered inter-running of such paramount importance as to quite justify a general enactment. Again, Mr. Sellon advocated a general enactment, while Mr. England (of the Wakefield Light Railway Company) considered it unnecessary, holding that the managers were quite capable of settling such matters. Two or three humorous incidents arose out of the question of changing crews at the boundary. The president having expressed himself in favour of this plan for rural districts with an infrequent service, such as a car every 20 minutes, Mr. Sellon retorted, "Every 20 minutes! Why you would do better to run a donkey-cart." An animated discussion ensued, which was terminated by the president explaining that he had not suggested such a method for urban traffic, but only for sparsely-populated districts, where the service must often be relatively infrequent. Mr. England candidly acknowledged himself an opponent of this system. It is too expensive, he remarked, because when the car reaches the boundary the men are apt to go "round the corner," so it needs an inspector to look after the men, and a traffic superintendent to look after the inspector. Altogether, the meeting was of considerable interest, and the importance of the subject made it more regrettable that clashing with another ceremony prevented a representative audience from being present.

Torpedo-Boat Construction.—There was an exceptionally large attendance at the meeting of the Junior Institution of Engineers on Saturday, when a paper, entitled "Some Points of Interest on Torpedo-Boat Construction," was read by Mr. H. E. Yarrow, Stud.I.C.E., of Poplar. Commencing with considerations with respect to the hull, the author showed the importance of realising in the design the maximum strength with the minimum weight, uniform elasticity throughout its length being essential. Any sudden change of section in these lightly-constructed vessels formed a source of great danger, and it was quite possible by adding material to reduce the actual strength. Passing on to questions with regard to riveting, hot *versus* cold riveting processes were discussed, the latter being advocated as possessing advantages over the former. In the best work the holes were drilled in preference to being punched. It was of great importance to minimise vibration as much as possible, and the author illustrated by means of lantern slides the effect of a properly-balanced engine on the stability of the boat itself. The superiority of a four-cylinder as compared with a three-cylinder engine in this respect was indicated. The necessity of more attention being given to the design of auxiliary engines was

Digitized by Google

commented upon, and considerations in regard to lubrication were entered into, the author insisting that all internal lubrication should be dispensed with absolutely, both in the main and in the auxiliary engines. No real difficulties occurred in this, and the good results on the working of the boilers were obvious. With the use of high-pressure steam the paper showed how imperative it was to specially consider the best practice relating to steam-pipes; those of small diameter being recommended for various reasons, amongst them being superheating of the steam and ensuring that each boiler was developing approximately its proper proportion of the power required. Referring to steam-turbines, the author held that although they possessed many advantages over reciprocating engines, they could not be regarded as economical for varying speeds as in torpedo-boats. He alluded favourably to the explosive type of engine, which was developing so rapidly at the present time. It presented many characteristics specially advantageous to its adoption in the class of boat under consideration, including elimination of the boiler-room staff, and general reduction of weight. The paper was succeeded by an animated discussion.

Magnetic Storms.—The communication of Mr. E. W. Maunder last week to the members of the British Astronomical Association, upon the connection between sun spots and magnetic storms, aroused a wide degree of interest in scientific circles. Mr. Maunder has lately been engaged in investigating this subject, which has been debated for 60 years. In 1892 Lord Kelvin declared that magnetic storms cannot be due directly to magnetic changes in the sun, which view was already entertained by certain scientists. Another hypothesis was that they are due to streamers, analogous to the cathode rays in Crookes's electric vacuum tubes, which impinge on the earth. This was put forward by the late Prof. FitzGerald at the time of Lord Kelvin's address, and has recently been elaborated by Arrhenius and others. But authorities have never denied that magnetic storms are due to some kind of solar activity. An observational difficulty that confronts the enquirer is that in some cases the appearance of sun spots is not followed by magnetic storms, and in other cases there are storms without sun spots. Mr. Maunder said he had often considered the question, and, though he was satisfied that there was a general agreement between the appearance of spots and of storms, especially when only big spots and big storms were taken into account, yet he could not get that agreement to go far enough when all the disturbances were taken into consideration. Nor did he make better progress when he took other solar features, such as faculæ or prominences. But when examining the Greenwich records for the 20 years 1882-1901, he noticed that in many cases the disturbances occurred at a mean interval of $27\frac{1}{3}$ days, the apparent period of the sun's rotation, and he then began to compute the longitudes of the centre of the sun's disc at the time of the beginning of the disturbances. This led him to the discovery that of 276 storms one-third were arranged in pairs equal to one rotation of the sun, while three-quarters showed a rotational period in one form or another. The conclusions he arrives at are that our magnetic disturbances show a very strongly marked tendency to recur with the return of certain definite meridians of the sun to the centre of the disc. The consequences are revolutionary. "First of all," Mr. Maunder states, "it decides beyond question the 60 years' controversy. The origin of our magnetic storms does lie in the sun. Next, it introduces a totally new conception of the magnetic action of the sun. It is not from the whole surface; it is not radiated equally in all directions. But it is from certain restricted areas and along certain narrow lines." The figures and data on which Mr. Maunder's views are based have excited a good deal of attention among scientists, as until these have been investigated criticism is impossible.

Electrical Finance.—The conditions which govern the selling price of electrical energy are by this time quite clear to the electrical engineer. We regret to say that the average consumer of electrical energy is not so conversant with the governing factors which go to make up the selling prices, and hence we find complaints against those scales of charges which give preference to the long-hour consumer. We have this week received a cutting from the *Southwark and Bermondsey Recorder and South London Gazette*, which clearly shows that the Bermondsey Municipal Association are lamentably ignorant on this subject. This association have hired a column of our contemporary in which to express the views of its members, and in last week's issue it dealt with the electric lighting undertaking. This, we are assured, is in a very bad way, and we think it only fair to the writer of the article to reproduce one paragraph of his condemnation in full. This reads as follows: "The nature of the business militates against all prospects of success, inasmuch as the bulk of the supply is for power purposes, every unit of which is sold under cost price. During the half-year ended Michaelmas 44,031 units have been sold to private consumers for lighting and 109,395 for power purposes. The supply for power represents the disposal of wastage, electricity not being, as gas, storable. Whoever heard of a business producing more than twice as much wastage as saleable materials? *Mirabile dictu*, the committee seems bent upon extending this unprofitable department of their business, having invested considerable capital for certain contracts, every unit of which represents a loss of at least 1d. Power: number of units produced, 109,395; cost of manufacture, according to official figures at 2·23 per unit, £1,139. 10s. 8d.; price obtained, including meter rent, £866. 7s. 9d.; loss on half-year, £273. 2s. 11d. Lighting: number of units produced for private consumers, 44,031; cost of manufacture, according to official figures at 2·23 per unit, £416. 19s. 9d.; price obtained, less 10 per cent. for units unaccounted for, depreciation, etc., £672. 7s. 4d.; profit in half-year, £255. 7s. 7d.. Net loss in half-year, £17. 15s. 4d. To this net loss must be added instalments of loan, interest, half the cost of the dust destructor, provisions for a sinking fund, depreciation of machinery, etc., and many other incidental expenses, making in all a gigantic total." The article in question is signed "Municipal"; we should much prefer that the writer had given his own name, so that we could refer him personally to numberless articles which would show him the error of his ideas on the above subject. The naïve idea that the supply of power represents the disposal of wastage, because electricity cannot be stored as gas can, is laughable, but it is lamentable that a man who undertakes to educate either the Bermondsey Municipal Association or through it the Bermondsey ratepayers should not take the trouble to ascertain the facts before he puts the same into the public press. His idea that the average works cost per unit is, therefore, the cost of every unit shows that he has not done so, and hence his whole remarks on the question are misleading, untrue, and quite valueless.

Junior Institution of Engineers.—A visit was paid by the members of this institution on Saturday to the London Coliseum, where they witnessed a demonstration of the revolving stage. There are three concentric rings or stages, the outer one and the intermediate being 12ft. across and the middle circle 25ft. 7in. The entire diameter across the three is 75ft., and so accurate has been the

Digitized by Google

building up that only 1in. of clearance is necessary to permit of the tables running separately, without rubbing or touching. The tables are built up on rolled-steel underframes, 9ft. high, and instead of the motive power and wheels being on the carriages as in a tramway, the engineer (Mr. E. Wingfield Bowles) has designed a runway on the underframes which runs on the motors, thereby reversing the usual order of things, and securing considerable lightness, absence of moving contacts for the current, and a great reduction in the noise. The electric motors, 14 in all, used for driving the stages are all set on adjustable beds for levelling up to the level of the fixed or permanent stage surrounding the outer ring, and the motors are all controlled from the special switch pillars on a raised gallery on the prompt side of the stage, which overlooks every part of it. The signalling to the drivers is effected by means of a special form of ship's engine-room telegraph worked from a position on the stage level, where the stage manager has also to hand speaking-tubes, lamp-signal keys, and telephones to all the points where engineers are stationed to work the numerous electric apparatus. On receiving a signal on his dial the table driver has only to turn to the controller wheel, and the table, 75ft. in diameter, can be turned, stopped, and reversed, the actual controller or switches being in a chamber below the stage. There are other electrically-driven devices which can, in an emergency, be worked by hand at sufficient speed to prevent an absolute breakdown of the entertainment. The scenery proper will be hoisted by compound electric-driven winches. When complete there will be 30 electric motors at work in the building. There are 12 miles of cable in connection with the various circuits on the stage, and the consumption of electrical energy will, it is stated, exceed by 50 per cent. that of any other theatre or music hall in London, though every possible device for saving current has been brought into play. Fireproof cables and a completely connected and earthed steel-tube conduit system are used in connection with the illumination of the building. The illuminating power on the stage is equal to about 5,000 8-c.p. incandescent lamps, and the auditorium has upwards of 2,000 similar lamps. The public parts of the theatre are divided into two separate installations, supplied by two independent companies, so that, in the event of failure of the one supply, the public may have in every part a sufficiency of light from the other. These installations are kept entirely apart from the stage supply, so that no accident on the stage can affect the lights in the public parts of the house. Special novel effects will be produced by means of electric projectors and the biograph lanterns in various parts of the building, for which fireproof rooms have been provided as part of the structure. The main stage switchboard has 85 distinct switches, which are so combined that, by interlocking and automatic releasing, it is possible for one man to control all the lights on the stage and produce combinations of colours at any strength.

Royal Society.—The anniversary meeting of the Royal Society was held at Burlington House on the 30th ult., when the president, Sir William Huggins, delivered an historic survey of the society's existence. In the evening the anniversary dinner was held at the Hôtel Métropole. Engineering, science, law, politics, medicine, and literature were all represented. Mr. Arnold-Forster, M.P., in giving the toast of the society, created some amusement by remarking that it was a somewhat dangerous thing to turn a politician loose among such a distinguished collection of scientists, because in the practice of British politics there was probably less science used than in any other pursuit known to man. Since entering the Government he had every day been more and more impressed with the need for a greater knowledge in our public life of what scientific men were thinking, what they were doing, and what they hoped and meant to accomplish in all the great departments of scientific life throughout the globe. There was absolutely infinite opportunity for the work of trained minds in that very important department of our national life, the public service. Even in his short official life, he was glad to say that he had lived to see some progress made in the direction in which he wished to see this nation travel. Glancing at the list of their fellowships, he found that no fewer than 31 Fellows of the Royal Society either were or had been officers in the Royal Navy or in the army. He paid a high tribute to Sir William White, Prof. Ewing, and other Fellows of the society for their services to the navy and in various spheres. Scientific establishments were particularly wanted for the army and navy. He looked to Sir Arthur Rücker, in his great fairy palace at Kensington, to establish a great metallurgical laboratory where they might concentrate all the work they were now trying to perform with regard to metallurgy, which was so important in all manufactures both for the navy and the army. He should look to another Fellow—Sir Oliver Lodge—to re-create our public schools. The President, in tracing recent developments of science, said that at no time in the past had the pace of scientific progress been so rapid; at no time so imminent the clearing away of the mist of the unknown from many points of strategic importance for the conquest of more knowledge of the inner relations of things. In physics only a few years ago Prof. J. J. Thomson took by storm the outworks of the central citadel of nature—the chemical atom. His later brilliant attacks, aided by the new artillery of radioactive radiations, might be said to have carried the keep itself. This stronghold of matter was found to be a place of positive electrification in which swarms of negative electrons are winging their mazy rounds. Material mass gives place to the electric mass of moving electric charges. On this view the chemical elements, each with its individual properties, but all falling into family groups according to a periodic law, have their origin in differences in the number of the electrons and in the figures of their giddy dances, whirling within the atom. In a eulogy of the new medallists he said that the Copley medal, the society's highest distinction, was awarded to Sir William Crookes for the extensive researches in chemistry and physics by which he had enriched physical science in many departments. The Rumford medal was awarded to Prof. Rutherford for his researches on the properties of radioactive matter, and it was not too much to say that by his detection and investigation of radioactive emanations and their transformations he had added an unexpected domain of transcendent theoretical interest to physical science. The Davy medal was awarded to Prof. Perkin, jun., for his masterly researches in the domain of synthetic organic chemistry, carried on continuously during the last 25 years, beginning with the cyclic compounds of carbon through his work on camphoronic acid, the constitution of camphor and other bodies, to his more recent work on the synthesis of terpin. Sir Joseph Swan had gained the Hughes medal for his invention of the incandescent lamp, and his other inventions and improvements in the practical application of electricity, also his inventions in dry-plate photography. "Was it too much to say," asked the President, "that Sir Joseph had abolished night?" Sir Joseph Swan, in replying, said that all the medallists that day had gained awards for research and discovery except himself, who was recognised for invention. He would point out how often invention had coincided with investigation, and had led to discovery.

RUNNING POWERS.*

BY STEPHEN SELLON, A.M.I C.E. (MEMBER).

"Whereas the construction of the tramways, which are hereinafter described, will be of public and local advantage."

The above words, or their equivalent, will be found in the preamble of many Tramway Acts; they are, therefore, the ostensible primary justification for the granting of powers for legalising tramway construction. They are the *raison d'être* of tramways, and form, therefore, the text of this discourse. Having obtained powers, the tramway undertaker's obligations do not cease on construction, but continue during working, and the maintenance of his monopoly depends on the manner in which he fulfils his duties. *Public* and local advantage! Happily chosen—the words are in accordance with the spirit of highway law; the public road is the King's highway; free, peaceable unobstructed passage is the right of every wayfarer thereon, and the Crown, representing the whole State, safeguards that right. The road authorities have no right over the roads they maintain superior to those of the traveller from the most distant county or foreign lands. They have duties in respect to the roads; mainly to keep them open, safe, and unobstructed to all comers. They have certain legal powers given them to enable them to perform those duties and to meet the consequent expenses, but proprietary rights or powers to obstruct, tax, or detain the traveller are not in their possession.

These ancient elementary principles of English highway law apply to tramway politics in other directions, which lead me away from the present subject; but they are cognate to that, because, in the first place, a tramway is an improvement of the highway on which it is laid, increasing its capacity and utility, cheapening its use, and saving the time and strength of the traveller. It follows, in my view, that those to whom Parliament entrusts tramway powers hold substantially the same position towards the public generally as highway authorities so far as their powers go; that they are equally obliged to afford all travellers the maximum facilities within their power; and that Parliament is entirely justified in ensuring that "the public and local advantages" which the tramways authorised can afford shall not be limited by unreasonable conduct on the part of the undertakers, whether due to sentimental, selfish, or capricious motives. That tramway undertakers are authorised to collect fares for the use of the advantages they provide is an incident which does not affect my main principle. It means that the extension of travelling facilities is only available to those who can tender the legal fare, but this is a limitation in number, not in kind.

It has been my lot during the last two sessions of Parliament to hear many objections raised against running powers. It is difficult to treat any of them seriously, and it is, therefore, not surprising that the learned counsel, obtaining no solid grounds for rejection from the mouths of his witnesses, found himself forced to claim the application as unprecedented. "Precedent" is a magic word; parliamentary counsel, with no arguments against a proposal evidently for the public advantage, cry "What precedent have you for such a demand?" This was the continued cry of the learned counsel for Birmingham and for Newcastle-on-Tyne during the recent running-power cases brought before Parliament, and they busied themselves to show that there were no precedents, and that cases claimed by the other side as precedents lacked this or presented that important feature, and so differed entirely from the cases under discussion. The only other objection urged is founded altogether upon ignorance of what "running powers" really means. Again and again the objection has been raised that the running company is desirous of usurping the rights of the owners of the tramways, and confiscate to itself the management of the tramways run over. An idea, if it were not founded on gross ignorance, would be worthy only of the maddest inhabitant of Bedlam. I cannot do better than quote as an example the class of objection I mean—viz., a petition which was seriously and gravely presented to Parliament in the session of 1904 against the proposals made in the Bill of the Tyneside Company for running powers over the tramways of the Newcastle Corporation: "We, the undersigned citizens of the city and county of Newcastle-upon-Tyne, do humbly pray that your honourable House in considering the Bill intituled 'an Act to confer further powers upon the Tyneside Tramways and Tramroads Company, will refuse your consent to those clauses in the Bill in which the company asks for compulsory running powers over the tramways of the Newcastle-upon-Tyne Corporation, because we are strongly of opinion that the proposals in the company's Bill are objectionable, retrograde, and against the public interest by reason, amongst other things, of their interference with the principles of municipal self-government—the adverse effect which, if carried out, they would have upon the smooth and efficient working of the present excellent tramway system of the Corporation, the curtailment of the existing through fares in the city and loss of central control so essential to the working of a good tramway system, the making subservient of the great central system to the small outside system and the inconveniencing of hundreds in order to convenience a few individuals, and because we consider them an invasion of our rights as a self-governing community." Obviously the lack of a precedent or objections of the character indicated do not condemn a proposal, but as so much importance is attached to it, and there is some interest and guidance to be obtained from the history of running powers, I will just go over the matter briefly.

Very early in the history of railway working in this country it was found that railway companies whose lines junctioned with each other did not always give either the passenger or goods traffic the advantages that the physical junctions rendered possible. Rebooking, changing carriages, transhipment from truck to truck, with delays, additional terminal charges, and other inconveniences and monetary losses, resulted. It is not generally known that railways were originally intended as highways for accommodating the engines and carriages for the conveyance of passengers and goods by other companies or persons, and that this principle applied with equal force to railways or tramways constructed along a public road is instanced by the terms and conditions under which the promoters of the Swansea and Mumbles Railway obtained their powers. Section 92, Railways Clauses Act, 1848, reads as follows: "It shall not be lawful for the company at any time to demand or take a greater amount of toll, or to make any greater charge for the carriage of passengers or goods than they are by this and the special Act authorised to demand, and upon payment of the tolls from time to time demandable all companies and persons shall be entitled to use the railway, with engines and carriages properly constructed, as by this and the special Act directed, subject, nevertheless, to the provisions and restrictions of the Railway Regulation Act, 1842, and to the regulations to be from time to time made by the company by virtue of the powers in that behalf hereby and by the special Act conferred upon them." By the enactment of the Railway and Canal Traffic Act, 1854, Parliament obliged all companies whose lines junctioned to provide for through booking, through goods rates, and to permit the through running of carriages, wagons, and trucks. The arrangements between companies, generally known as "running powers," differ from "facilities" in that they permit a railway company to run over the lines and use the stations of another with its own engines and servants.

There are abundant examples of running powers by agreement between railways, sometimes one-sided, sometimes mutual, and there are a number of cases where Parliament has granted running powers by compulsion. In the latter case Parliament appears to have acted upon principles which may be classified generally under the following heads: to save the running company useless expenditure in duplicating lines or terminal accommodation; to meet an obvious public convenience which could not be left at the mercy of the possible unreasonableness of the company in possession; to remove the obstruction wilfully offered by a company to the traffic of another company, or where a company has failed to afford proper facilities; as a statutory confirmation of an agreement entered into between two companies, so that the public advan-

* Paper read before the Tramways and Light Railways Association, Dec. 1.

Digitized by Google

tages so gained should not be at the mercy of future quarrels or divergence of interests between the contracting companies.

In such cases the principle seems to have been conceded that the running company should take no profit on fares earned on the owning company's lines. It pays its own train expenses, and very frequently some charge by the owning company for terminal services and facilities. There are a few exceptions to this rule of no profits. It can, therefore, fairly be stated that the principles regulating running powers are fairly established in most cases in railway legislation and traffic. I propose to show that there is not the slightest reason why similar principles should not be applied to tramways, whether authorised under the Tramway Act or as tramroads, or under the Light Railways Act, that there are abundant examples of running powers by agreement, mutual running powers, and compulsory running powers as between tramways, and to go a little further by showing that while "facilities" generally meet railway conditions, those of tramway traffic make facilities wholly impracticable for the attainment of the much-desired public advantage.

The earliest case of running powers that I am able to find as regards tramways was in 1874, when the Swansea Tramway Company obtained compulsory running powers over the Mumbles Railway, and for many years the curious spectacle was observed of a horse tramcar sandwiched in between the steam-cars of the Mumbles Railway, an obviously inconsistent mixture of traffic resulting in inconvenience, which was therefore discontinued a few years ago by agreement, subject to compensation. In 1882 powers for running into Dudley by the South Staffordshire and Birmingham and Midland were obtained; in 1882 running powers were obtained over the Walsall and Wednesbury and West Bromwich Tramways by the Staffordshire Tramway Company; in 1884 the London Street Tramways obtained running powers by agreement over the North Metropolitan system in Gray's-inn-road between Holborn and the junction of Theobald's-road with Clerkenwell-road; Plymouth Corporation over the Stonehouse Company's line, 1900; in 1900 Poole Light Railways and Christchurch and Bournemouth Tramways over the Bournemouth Corporation Tramways; Glasgow Corporation over Paisley Company, 1901; in 1901 the Spen Valley Light Railways over a portion of the Batley Tramways; Salford over Manchester, 1902; Metropolitan Electric Tramways over Walthamstow, 1902; South Lancashire over St. Helens, 1903; Brighton and Hove Company over Worthing Corporation, 1903; Tyneside and Newcastle, 1904; Wakefield Light Railways over Ossett, 1904; Leyton over Lea Bridge, 1904. Running powers have been arranged between Oldham, Ashton, and Hyde Company and the Stockport Corporation over portions of the two systems by agreement; Dundee and Dundee and Broughty Ferry Company; Manchester and Ashton, and other outside local authorities; Wakefield and Leeds; Aberdeen and Aberdeen Suburban; East Ham and West Ham; City of Birmingham Company and Birmingham Corporation Tramways.

The advantages of running powers, which enable two or more systems to be linked up and worked without any change of car, are so obvious, both on the grounds of public convenience and of financial benefit to the owners, that it is difficult to understand the existence of opposition. I have made many observations on the effect of a break of service on the traffic of tramway systems. In every case the effect of a break is to reduce the earning capacity on the routes immediately affected from 15 to 50 per cent., whilst there is frequently a much wider spreading of the effect than could be anticipated, and any gain on alternative routes between the same points is far less than the direct loss. Conversely, directly the connection is re-established, the traffic returns to the normal conditions. The favourable effect of a "through" connection established between two systems previously worked with a break of service confirms these cases. As an illustration, I may instance the well-known Newcastle and Tyneside case. By the courtesy of Mr. McLellan, I am able to quote figures obtained from his statistics of traffic. The Newcastle tramways terminate in open country about half a mile from Wallsend. The Tyneside Company's line runs up to the same point through Wallsend from North Shields. During the month of April, 1904, when a change of car was necessary to enable passengers to get from the Corporation's system to the company's system, or *vice versâ*, Newcastle brought 48,796 passengers up to the terminus, out of which the company carried on 11,414, leaving 37,382 passengers on the road. Now, from the nature of the country, practically the whole of that number must have been bound for Wallsend and preferred to walk the half-mile stage instead of mounting another car. During the month of September both the Corporation's and the company's cars ran through, and 48,409 passengers arrived from Newcastle at the point mentioned, 36,305 of whom went on to Wallsend, thereby reducing the figure of 37,382 passengers walking on to 12,104; and, mark you, this result was obtained immediately upon the through service being run. Similarly, travelling towards Newcastle in April, 16,070 passengers only were carried to the termination of the company's tramways, whereas in September 29,930 availed themselves of the through cars on this stage. Mr. McLellan further informs me that the through service has undoubtedly generally stimulated the tramway traffic. In considering these figures, it must be borne in mind that the month of April took in the Easter holiday traffic, and that between April and September the electrified service on the North-Eastern Railway came into operation.

Another typical instance I may take is the case of Birmingham and Aston. For a number of years a through service was run from the centre of Birmingham to Aston. During the last six months of this through service 449,853 passengers were carried monthly, and from statistics taken it was found that 72½ per cent. of this number (326,142) crossed the city boundary into the Aston district. Owing to the conversion of the tramways from steam to electric traction a break at the boundary was necessary, and it was then found that the number of passengers carried monthly in the Aston district averaged 178,671, showing a decrease, therefore, so far as Aston section of the tramways is concerned, of about 50 per cent. Now, I know it may be said that the Birmingham section of the line did not suffer at all from this break, but it is necessary for me to point out that the first 1d. stage on this line from the Birmingham end extended some distance over the boundary. When Birmingham started the electrical service to the boundary, they, of course, charged a 1d. fare, so their passengers had to pay the same fare for travelling a shorter distance by an improved method of traction, and at the same time had the undoubted inconvenience of walking a portion of their journey. The incident that the gain or loss of traffic may not be equally shared between the two undertakers does not affect the argument of public convenience. It may affect the terms.

Another instance is that of the Leith and Edinburgh Tramways. The break occurred at Pilrig when the Edinburgh section of the line was cabled. The loss entailed here was about equally divided between the two sections, totalling to £6,000 per annum. The length of route between Princes-street, Edinburgh, and the centre of Leith is about a mile and a half, so that the loss in money mentioned is equivalent to £4,000 per mile per annum, which is a good deal more than many tramways get as their rate of gross earnings.

There are marked differences between railway and tramway traffic conditions which materially affect the conditions and terms of running powers. Generally, compulsory running powers are exercised by one company over the line of another in respect to through traffic only, the local traffic being served exclusively by the owning company. Such an arrangement is clearly impracticable on a tramway; the foreign car must be available for the local traffic as well as the through traffic. This also applies on railways with a traffic similar to that of tramways; for example, the several railway companies who run trains on the railways of the District and Metropolitan Companies.

Another difference arises in respect to the utility of "facilities" in the railway sense as distinguished from running powers. On a continuous railway journey it makes little or no difference to the convenience of passengers that the locomotive is changed at a particular station, or that

Digitized by Google

the guards of one company are relieved by those of another. But it appears to be found convenient by the companies themselves to employ through guards wherever the traffic is large. The tramway case is quite different. Changing car crews at a boundary must lead to some waste of men's time and to delay of the traffic, for clearly there must be a spare or overlapping crew available, or cars in opposite directions must await each other's arrival at the boundary. The fact that the car is also the locomotive, and that the conductor is also the booking clerk, introduce other objections to the exchange of crews. "Facilities" which only amount to the issue of through tickets with a change of cars at the meeting points need not be considered, as I have already shown that even where there is no change of ownership, and therefore every endeavour made to minimise inconvenience, a great loss of public advantage, and, therefore, of traffic, results.

I therefore take it that running powers between adjoining tramways are necessary for the full accomplishment of their public purpose, and, incidentally, for the best commercial results to the undertakers as fully proven; and submit that any tramway undertaker, whether municipal or company, who stands in the way of such conveniences, is abusing his position in just the same way as would a road authority who built walls or dug ditches across the roads at its boundaries, in order to compel every passenger to climb over or splash through them as the penalty for intruding on "our roads" or leaving the "sacred territory."

The justification of compulsory running powers is, of course, the public necessity. It ought not to be tolerated that parties entrusted by Parliament with tramway powers should be permitted by unreasonable conduct to prevent or hinder the full public use and advantage of any means of connection. Experience shows that, unfortunately, reliance cannot always be placed upon the reasonable conduct of the parties. Whether it has been a corporation or a company that has been unreasonable is not to the point, but there does seem a greater tendency on the part of corporations to object to through running on such sentimental grounds as that it is "an intrusion on our tramways," and on such "practical" grounds as that there are difficulties in controlling "foreign" car crews, that the town tramways are already pressed to their full capacity, that there will be ticket and account difficulties, and even, *reductio ad absurdum*, difficulties in apportioning responsibility for accidents. The only one of these "practical" objections worthy of discussion is that of the full occupation of the city tramways by the local traffic. If this is a fact, it shows that further tramway facilities are necessary, say, for example, by the construction of lines more or less parallel to the through routes, and I would submit that, given the maximum possible number of cars on the city lines, there will be a balance of advantage in having some of them running through, to and from the suburban districts, even though some short-distance or local passengers are displaced by long-distance or through passengers.

In the application for running powers into Birmingham the Corporation were prepared to give what they called "facilities," which I have already distinguished from running powers. This meant, as we all know, and as Mr. Bellamy was good enough to tell us in evidence, change of crews at the boundary, which in his opinion was all that was necessary and perfectly workable. Picture to yourself for a moment in the crowded streets of Birmingham a service of cars with a headway of every few seconds, and fresh conductors and drivers popping up and down from the cars arriving or leaving the city boundary, and you have a spectacle worthy of a Drury Lane pantomime. A few months after the rejection of the Bill for running powers, the Birmingham Corporation were fortunate in obtaining the advice and the co-operation of one of the best known and most accomplished tramway managers in this country. The following extract from a speech made by Mr. Alderman Beale, the chairman of the Tramways Committee of Birmingham, in May of this year, is far more eloquent and convincing than any words of mine as to the results: "Going on to explain to what extent the Corporation had given way, Alderman Beale said that when the Corporation went before Parliament it objected to the granting of powers to the company to run through the city. The Corporation rather favoured the Liverpool system of a change of crews at the boundary. The company did not like that, and the committee had given way to the extent of allowing the company's cars to run into Birmingham in charge of the company's servants. Really, on reflection, the objection to this seemed to be sentimental rather than practical, and in some respects the arrangement would be an advantage, because they had been able to provide that the whole risk regarding a certain car should be borne by the body to which it belonged."

The only cases where running powers have been settled by reference are those of the Swansea and Mumbles, and the Glasgow and Paisley of this year. The Swansea case, being a very peculiar one and a very ancient one, it is unnecessary here to consider it. It may be interesting, however, to quote the case of Glasgow and Paisley, recently determined by the arbitrator, Lord Balfour of Burleigh, who was appointed by the Board of Trade.

Glasgow in 1901 was granted running powers into the centre of Paisley, and having decided to exercise this power, and not being able to agree with the Paisley Company as to terms and conditions, the matter was referred to arbitration. The distance from Glasgow to Paisley is 7½ miles, one mile of which is owned by the Paisley Company. Glasgow proposed to charge a "through" fare of 3½d., and it was suggested that the company was only entitled to receive the proportionate fare in mileage less a sum for working expenses. The company, however, claimed their statutory fare with no deductions, and a sum representing 6 per cent. interest on the cost of constructing a siding that had by the Act to be provided for the accommodation of the Glasgow cars. The company obtained by the award their full statutory fare for local traffic, and inasmuch as they charged for their own "through" traffic 1d. for 1½ miles (being three ½d. stages), they were allowed ⅔d. for each "through" passenger from Glasgow, less 3 3d. per car mile for working expenditure Another interesting part of this case is that Glasgow have to pay for the current they use while on the Paisley lines. The principle is, therefore, established that the owning authority is entitled to receive a sum per passenger in excess of the proportionate mileage for the "through" fare, and, in addition, the Corporation have to pay the costs of terminal service and facilities. The decision seems fairly to represent the views held by railway managers of the past, such as Sir Edward Watkin, who explained to the Railway Companies Amalgamation Commission in 1872 that the owning company was entitled to receive something beyond the ordinary fare on account of the increased traffic receipts accruing to the running company due to the running powers and also a proper sum for terminal accommodation.

It has been already stated that running powers on a railway do not mean profit to the running company. In case of mutual running powers on two systems of tramways this practice should, I think, still prevail; but in cases where there is no mutuality in running powers, like Glasgow and Paisley, it is a very different proposition. Glasgow, by obtaining a through service into the centre of Paisley, with a population of 120,000, instead of having to stop at the boundary, is fructifying some miles of their barren line to the detriment of the Paisley Company; whereas, if Glasgow and Paisley had mutual powers, this one-sided advantage would not exist. It is clear that in all cases where an outside company desires to gain admittance to the centre of another tramway system it is proper that the local service should not be interrupted, and that, in adjusting terms and conditions, if running powers are granted into the centre of the existing system, the effect of the break at the centre ought to be taken in account as a set off against any advantage the owning company may be said to secure in extra traffic by the connection.

Having regard to the importance to the public of the advantages I have endeavoured to indicate, which experience shows cannot but result from the working of tramways connecting important districts as a through service free from obstruction, I venture to suggest that this association will perform a most useful function by making every endeavour to remove the many prevailing and unfounded misapprehensions which exist, by the dissemination of

Digitized by Google

information bearing upon the subject, and so abolish what, I think, must be conceded to be a most mischievous obstruction to the better and more useful developments of interconnection by means of through traffic.

The following is a summary of the discussion:

Mr. Alfred Baker, the president, said that if compulsory powers really meant what the author indicated, he could see no very great objection to them. But did they? Had the seekers after compulsory running powers always been willing to forego all the profits from the lines over which they desired to run? He thought not. If the British Electric Traction Company had never wanted to make any profit within the city of Birmingham, everybody had been under a most extraordinary misapprehension; but he must congratulate the author upon his definite pronouncement that night, that through powers should not mean profit to the running party in respect of the other owner's area. Recalling the details of the Birmingham case, he stated that the company applied to Parliament to coerce the Corporation into granting through powers, and the learned counsel for the company laughed to scorn the Corporation's suggestion that the matter was quite capable of friendly arrangement. The Corporation were quite prepared to grant through powers voluntarily, but objected to compulsion. Happily, Parliament adopted the Corporation's view, and the sequel proved that the question could easily be adjusted by negotiation. The arrangement was working exceedingly well, as he believed all such arrangements would where both parties tried to do the right thing. Each party provide a number of cars proportionate to the route mileage in their respective areas; the total receipts are divided in proportion to the route mileage, except that 5 per cent., representing those passengers riding exclusively within the city, is reserved to Birmingham; each party pays its own expenses and is responsible for accidents through its own servants' negligence. In the case of two large systems joining each other, it would only be necessary to divide fares on the stage crossing the boundary. The author had criticised the evidence given by Mr. Bellamy in this case in regard to change of crews at the boundary. Mr. Baker strongly defended Mr. Bellamy's attitude so far as regarded rural districts where the service was comparatively infrequent. It would be fallacious to lay down hard-and-fast terms for inter-running, but he thought that those adopted at Birmingham might generally be followed with safety. He certainly did not believe in a dog-in-the-manger policy, but he did think it the bounden duty of every local authority to protect the system it had built for its citizens. The danger of compulsory running powers was that municipal lines might be exploited by unscrupulous promoters building lines in sparsely populated neighbourhoods, but this peril, he acknowledged, was less real than apparent, because if the principle that the running company should not make a profit over the other party's lines were established, there would be little inducement for such promoters to construct lines. The author justified compulsory powers on the ground of public convenience, but Mr. Baker believed that where there was a legitimate demand, public opinion would be quite strong enough to compel an unreasonable undertaker to come to terms.

Mr. Barber Glenn frankly confessed that he viewed the matter entirely from the company point of view, and could not participate in any feeling as to the "sacred" character of municipal territory. It was simply a case of public necessity. Whether the inside line was a city system and the outside one a suburban system did not matter, because terms could be adjusted. He quoted the case of a company of which he had been secretary for over 30 years. They had years ago made arrangements with an adjoining company for through running. The first agreement was that there should be a pooling arrangement on the basis of the respective number of cars. That did not work altogether satisfactorily, because, he remarked humorously, his manager wanted to exceed the receipts of the other party, with the result that there were suggestions of such irregularities as "hanging the road." Consequently an arrangement was substituted by which each party kept their own receipts and adjusted expenses fortnightly. This arrangement continued for years, and no difference ever occurred that was not settled in a few minutes. He also mentioned the case of a light railway with which he was associated. This line met a municipal tramway, and the authorities paid a certain sum for running over a mile of the light railway. The corporation were willing to pay a liberal sum for running over the whole of it, but they absolutely declined to entertain any idea of the other side running over their lines on any terms, presumably on account of the aforesaid "sacred" character of their territory. He deprecated threatening corporations that if they did not grant running powers the case would be taken before Parliament, but he thought there should be a general enactment that adjoining owners should negotiate. The case of Newcastle exemplified this, and he was sure that in a twelvemonth the Corporation would wonder why they ever opposed through running. In the case of busy towns the idea of changing crews would be ridiculous, but there were cases in which it would be simple.

Mr. E. F. Vesey-Knox, barrister-at-law, thought that where it could be arranged that the running party should pay an agreed sum per car mile and keep all the receipts, as in the case of the London County Council and the Bexley Urban District Council, it was a very simple way, and saved a lot of trouble. This was the arrangement between the London and North-Western and the District Railways in respect of the former running to the Mansion House. It was a reproach to our legislation that there was no provision for through running on tramways as on railways. Parliament had not legislated for tramways since the Act of 1870. It was all very well to say that public opinion would suffice to settle differences, but the public often divided itself into factions. He pointed out that it was not solely a question between municipality and company, as in Lancashire tramways were lying derelict because municipalities could not agree between themselves.

Mr. Blaine, manager of the West Ham Corporation tramways, lamented the absence from the paper of the question of terms. He then quoted the case of his system and that of the adjoining borough of East Ham. The obstacle had been relative earning capacity; but the parties had agreed as an experiment that each corporation should take the whole of the profit earned by its cars in the other district. He had since found that the traffic on the West Ham system averaged over 50 per cent. more than that on the East Ham system, but he considered the great object was to start through running, by a tentative arrangement if necessary, the results of which could serve as the basis of a permanent arrangement.

Alderman Ivey, chairman of the West Ham Electricity and Tramways Committee, pointed out that East Ham had compulsory powers for running over his Corporation's lines, and this, he was sure, acted as a useful lever in coming to terms. He strongly advocated that there should be compulsion on tramway undertakers to negotiate for through running. If necessary, the terms could be settled by some authority such as the Board of Trade, which, strengthened if need be on the technical side, would constitute a very suitable tribunal. The cost of a line was immaterial; its earning capacity should be the basis of an arrangement. Seeing that railways, which ran on their own land, had to grant through running, there was still more reason why tramways, which ran on public highways, should be compelled to do the same. Details of management could be settled afterwards. Why not let the respective managers discuss terms instead of holding a series of abortive conferences between the committees? The former, he believed, would be able to arrive at the basis of an agreement in a very short time. On the engineering side, the question of standard gauge and similar matters should receive most careful attention when applications for new systems were considered.

Mr. England, manager of the Wakefield Light Railways, stated that although he was a company man, and thought that everybody must agree that the policy of through running was not open to discussion, he strongly objected to compulsory powers. There was no need of a general enactment; the common sense of the managers would suffice. The manager of the Leeds Corporation tramways and himself had settled the heads of agreement at a single meeting, supplemented by a game of golf. A common time-table was agreed upon, and the service was accelerated, if necessary, by telephone. Leeds supplied the company with tickets in bulk, and as soon as the company's cars passed the boundary, journeying into Leeds, their conductors issued a Leeds ticket. The company gave a reduced through fare between Leeds and Wakefield, and issued a ticket which entitled the holder to travel between the two towns, but as Leeds was entitled to one penny of the fare charged for the through ticket, as soon as the car crossed the boundary the company's conductor issued a penny ticket to each holder of a through ticket. The company supplied tickets to Leeds in bulk, which were similarly dealt with by the Corporation. He objected to a change of crews, because when the men got off the cars, it needed an inspector to look after them and a superintendent to look after the inspector.

Mr. Sellon, in his reply, traversed Mr. Baker's view that there should be a change of crew where possible. Modern conditions would seldom permit of such a course. [A little passage-at-arms ensued here between the speaker and the president on this point, and on the question of the Birmingham negotiations, but after a few remarks on either side the misapprehension was removed, Mr. Baker explaining that he did not suggest change of crews for urban traffic.] Proceeding, Mr. Sellon stated that the granting of mere "facilities" had long ago been tried in the United States, and discarded as altogether futile. In reference to Mr. Blaine's comment about the absence of terms, he thought that gentleman had misconceived the purpose of the paper, which was to enunciate the general principles of through running. The terms only concerned the parties affected, who could arrange matters between themselves. He did not advocate a hard-and-fast decree for compulsory running, but simply a general enactment that if the parties could not agree upon terms, the matter should be referred to some authority such as the Board of Trade. This was absolutely essential. There would be no need to resort to it where the parties were willing to negotiate, but all owners were not, as witness Newcastle, which cost £10,000 for parliamentary proceedings, and was settled in a few days after the committee had expressed its views strongly. He welcomed Alderman Ivey's observation that attention should be given to such engineering matters as standard gauge when new systems were sanctioned.

Votes of thanks to the author and the president closed the proceedings.

THROUGH RUNNING—COMPULSORY OR OTHERWISE.

The importance of this question led us to ask the opinions of the numerous tramway chairmen, engineers, and managers throughout the country with respect to the advisability of through services, whether compulsory or not. The following are a few of the replies received, from which it will be seen that nearly all interested in tramways favour through running as a public boon. The opinions as to the methods of securing the advantages of through services are of great value at the present time. We have arranged the replies in groups, putting first those received from chairmen of

Digitized by Google

municipal undertakings; next, those from companies; and, lastly, those from municipal engineers and tramway managers.

GROUP I.—LETTERS FROM CHAIRMEN OF TRAMWAY COMMITTEES.

Darlington, Dec. 5, 1904.

Dear Sir,—I have much pleasure in replying to your letter of the 29th ult., but you must please understand that the views I express are my own, and not those of the Light Railway Committee of the Darlington Corporation, over which I have the honour to preside. The question of running powers over light railways is a subject I have paid much attention to. All railways, like highways, are constructed and maintained for the public advantage, and, in my opinion, light railway authorities, equally with highway authorities, are obliged to afford the public the maximum facilities within their power, and this view receives confirmation by Section 92 of the Railway Clauses Act, 1845, which enacts that upon due payment of tolls all companies and persons shall be entitled to use the railway with engines and carriages properly constructed, subject to certain restrictions and to the regulations made by the company; and by Section 108 (authorising the company to make regulations), no such regulations shall authorise the closing of the railway, or prevent the passage of engines and carriages thereon at reasonable times. You will thus see that the public have the right to use a railway with their own engines and carriages. Further, it is provided by Section 76 of the Railway Clauses Act, 1845, that owners or occupiers of adjoining lands shall be entitled, subject to certain restrictions, to lay down branch railways to communicate with any railway for the purpose of bringing carriages to or from or upon the railway, and that the company shall, if required, make openings in the rails, and such additional lines as may be necessary for effecting such communication.

Why should light railways be any different from ordinary railways? The objection so often raised, that the running company was desirous of usurping the rights of the owners of the light railway, and arrogate to itself the management of the tramways run over, is an idea founded on ignorance of what running powers mean. The principles regulating running powers on railways are well established. The ordinary mode of adjusting the conditions on which running powers shall be exercised is by giving 75 per cent. of the rate to the owning company, and 25 per cent. to the company exercising the running powers, and the Railway Commissioners will not, save except under very exceptional circumstances, vary the proportions, constant usage having crystallised them into a rule. The disadvantage caused by break of service is to reduce the running capacity on the routes immediately affected very considerably.

A through connection gives a great stimulus to tramway traffic. Running powers on light railways are equally necessary with railways for the accomplishment of their public purpose, and for the best commercial results. Any authority standing in the way of such convenience is abusing its position.

I regard running powers as a public necessity. Light railways were established in order to act as feeders to the railways, and in Darlington I strongly urged that the gauge should be 4ft. 8½in. instead of 3ft. 6in, so that the wagons for goods traffic might be interchangeable, but I was outvoted. There is no doubt that if the Light Railway Commissioners had insisted upon a uniform gauge of 4ft. 8½in., light railways throughout the country would have been, as they ought to be, of immense advantage to the community, as in time they would all have been connected up into one large system, which is impossible under present conditions.—Faithfully yours, EDWARD WOOLER,

Chairman of the Darlington Light Railway Committee.
Corporation Tramways, Huddersfield,

Huddersfield, Dec. 2, 1904.

Dear Sir,—In answer to your enquiry, I have no hesitation in expressing myself strongly in favour of intercommunication between tramway systems. It is unfortunate that the four county boroughs in this portion of the West Riding have all adopted different gauges, so that where the systems join up to each other an exchange of running powers is an impossibility. It has always struck me that the commercial advantages of such connections were enormously reduced by the fact of passengers being compelled to change cars. It seems to be part of the creed of public authorities to entertain feelings akin to jealousy of their immediate neighbours, and this fact will always be a stumbling block to intercommunication between municipal systems. Where the territories of several urban or rural district councils come between two municipal authorities, I think it would be to the benefit of everyone concerned to encourage a company to form the connecting links and to give them running powers to the centre of each of the terminal large towns. The financial wisdom of corporations going any considerable distance beyond their own areas is becoming every year more open to question as the results are ascertained. But a company can work a line and pay a dividend where a corporation would have to go to its ratepayers for assistance.

The whole question resolves itself into this—to give the public all the advantages and facilities possible so long as you can make a profit out of them (for I submit you are not justified in engaging in municipal trading unless you make a profit out of it). It matters not to the passenger whose car he travels in so long as he is conveyed to his destination as quickly as possible, at a reasonable fare, and with some approach to comfort. The Commons Committee gave not only Newcastle but all municipalities a wholesome lesson, and in future I hope we shall give more consideration to public convenience and less to municipal sentiment. There need to be no insuperable difficulty in apportioning the receipts and expenses if each party is willing to take what rightly belongs to it without trying to score off the other.—Yours faithfully, T. H. MOORE,

Chairman of the Huddersfield Tramway Committee.

Town Hall, Blackpool, Dec. 2, 1904.

Dear Sir,—The mayor desires me to acknowledge the receipt of your letter of the 28th ult. We are unable to give you any information at present on the question of intercommunication between tramway systems, as it is not yet in operation within the borough. I may say, however, that the Blackpool, St. Annes, and Lytham Tramways Company, Limited, and the Corporation are in negotiation as to mutual running powers over the two systems.—Yours truly, T. LOFTOS, Town Clerk of Blackpool.

Ipswich, Dec. 2, 1904.

Dear Sir,—I beg to acknowledge your letter asking for my views on the commercial possibilities of intercommunicating tramway systems. I regret that I have not considered the subject, and inasmuch as this Corporation's system is most unlikely to be linked up with any other for a great number of years, we shall in all possibility never have to consider the question. I should think it would be a terrible nuisance from a manager's point of view, both mechanically and commercially.

A toll per car per car mile run upon the basis of a profit on cost per car mile, interest, and redemption, with a percentage for depreciation, would seem the only basis. To attempt a ticket system would be impossible of achievement. No strange cars should ever be allowed on a single-line system.—Yours faithfully,

HERBERT J. W. JERVIS,
Chairman of the Ipswich Tramways Committee.

Preston, Dec. 2, 1904.

Sir,—In reply to your favour of Nov. 29, while I fully recognise the importance of the question of intercommunication and all that depends upon it, I have so recently been appointed chairman of our Tramway Committee that I feel considerable diffidence in passing any opinion whatever upon the subject, but I presume some arrangement for division of receipts and expenses could be arrived at somewhat on the lines of the Railway Clearing House working.—Yours truly,

E. J. ANDREW,
Chairman of the Preston Tramway Committee.

GROUP II.—LETTERS FROM MANAGING DIRECTORS AND ENGINEERS OF TRAMWAY COMPANIES.

16, Great George-street, Westminster, Dec. 1, 1904.

Sir,—In response to your letter of yesterday, I cannot, perhaps, do better than to endorse Sir John Dickson-Poynder's powerful plea which recently appeared in the columns of the *Times*, displaying a most searching consideration of the question of "through communication" in its relation to the greater question involved in respect to the housing of the people. There is much that I should like to say on the particular case of the Tyneside tramways, but I refrain from doing so because I might, as a representative of "private" (as distinguished from "municipal") enterprise, be regarded as prejudiced, and I prefer to maintain the controversy at the high level on which Sir John Dickson-Poynder has placed it. The issue is one of national importance, for the housing question lies at the root of a score of others. There would be greater efficiency, physical and mental, if the masses were enabled to live under healthier conditions than are possible in our great cities. The fundamental cause of overcrowding and its attendant evils are correctly described by him when he says, "there comes a stage in all city development when houses for the working classes cannot be provided at an economic rent by reason of enhanced site value," and, in my view, he is on equally safe ground when he adds, "the only remedy to hand is cheap and expeditious locomotion to the suburbs."

In the suburbs of London, and of all our great cities, there exists land and to spare on which houses for the working classes *can* be provided at an economic rent. The difficulty is that this land is remote—practically inaccessible A workman must live near his work. He—good fellow that he generally is—is willing to put up with many inconveniences for the sake of finding a healthy home for his family, but there are limits beyond which he cannot go. His wages do not provide much margin for travelling expenses. His daily journeyings must, therefore, be "cheap and expeditious," as Sir John concisely puts it. The question resolves itself, in short, into one of transit, in London inevitably of "through communication." Thanks to that combination of "tube," "rail," and "tram" to which I have pinned my faith, it is now possible for workingmen to live at Ealing, at Southall, or Hounslow, even as far afield as Hayes and Uxbridge, on the west, or at Richmond, Teddington, Twickenham, Hampton, and Staines in the Lower Thames Valley; for in these directions, and presently even far beyond, the electric cars of the London United will carry him swiftly and comfortably at a cost of something less than a farthing a mile.

In this connection I may, perhaps, quote some figures I recently submitted to the Royal Commission on London Traffic. In 1900 the passengers carried on the nine miles of horse tramway then existing in West London numbered some 8,000,000; and when, in promoting our first Electric Tramways Bill, I ventured to predict that, with the proposed extensions to Hounslow and Hanwell, we should carry at the rate of 25,000,000 passengers a year, it was thought I was over-sanguine. In point of fact, I under-estimated rather than exaggerated the figure, for the number of passengers in 1902 was 36,000,000, while last year, on the increased mileage, over 45,000,000 were carried. This was equivalent to our carrying 126 times over, in the course of the year, the entire population in the districts served. In 1900 there were only three workmen's cars running on the London United horse tramway system. We are now running daily upwards of 30 workmen's cars, and, on an average, we carry the passengers by those cars over five miles for 1d., the distance actually covered for that sum being in several instances over seven miles, and the average fare considerably under ½d. per mile. Whereas the total number of workpeople carried in 1900 under horse traction was only 142,000, the number has now risen to 2,562,000—an increase of 145 per cent. Concurrently with the expansion of our traffic there has been a remarkable growth of the suburbs in the West of London. Such is the demand for house property that estates where one dwelling formerly stood on its own acreage are now being cut up into building plots for houses that average from 20 to 30 to the acre, and land which a few years ago could not be sold advantageously is eagerly purchased and developed. Had these routes of which I speak not been continuous, had there been dual ownership with one of the owners of the exclusive mould of the Newcastle Corporation, it is inconceivable that this expansion of traffic and this extension of healthy residential areas could have taken place.

So much has been accomplished on this side of London that it is beginning to be possible for even those least richly dowered with imagination to realise how much more might be done if, not in the West of London alone, but in the North, the South, the East—and not merely in London, but in everyone of the great cities and towns of England—there existed such means of "cheap and expeditious and, what is essential to cheapness and expedition, continuous communication between the country and the town as electric tramways are capable of supplying. I use the phrase "capable of supplying" advisedly, for even in our own case the capabilities of electric traction as applied to tramways are only imperfectly realised in practice. Our undertaking is heavily burdened by the exactions of short-sighted local authorities; many miles of extensions which might to-day have been in operation have been delayed or abandoned because it was impossible for us to satisfy the rapacity of these bodies, and our connection with the underground electric railway system of the Metropolis is imperfect, and must remain so for the present, the London County Council having again prevented us from obtaining powers to carry out important connections between the London United and the Metropolitan District Railway. When the municipalities forget that they are tramway promoters, their views on housing questions and on intercommunication are sound enough. True, Mr. Benn spoke in the House of Commons on the Tyneside Bill as though it would be an intolerable grievance for the London County Council to be asked to grant running powers to tramway companies whose lines were prolongations of the municipal system. But Mr. Dickinson, representing the same Council, told the Traffic Commission that he anticipated no difficulty in arranging for running powers. "It is just as important for us to get people carried out to Middlesex as it is for Middlesex to get people carried into London." And again, asked if he proposed trans-shipment at the boundaries, Mr. Dickinson replied, "No, that would be absurd." The witness guarded his remark that companies should have running powers over the Council's tramways with the reservation that it was his personal view, but the personal view of a county councillor so prominent shows that the exclusive policy of the Newcastle Corporation is not universally approved in municipal circles.

The cheap, rapid, and convenient means of transportation in which lies the hope of improvement in the physical and moral condition of the people, can be provided only by the freest interchange of traffic, the most perfect physical connection possible between urban and suburban tramways, and in London between the tramways and the railways which have at present a monopoly of the congested heart of the City. Everywhere, in London and in the provinces, there is urgent need of recognition of the fact that "municipal" and "company" tramways must exist side by side for many years to come, and that as industrial enterprises, and as factors in the solution of pressing social problems, they will fail to achieve their highest possibilities if the "dignity" of corporation or the *amour propre* of individuals is allowed to stand in the way of effective combination for common ends. Effective combination means, so far as tramways are concerned, "mutual running powers," such as were sought last session for the Tyneside and will ere long be demanded by London.—I am, Sir, yours obediently,

J. CLIFTON ROBINSON,
Managing Director of the London United Tramways (1901), Limited.

Liverpool, Dec. 6, 1904

Dear Sir,—In reply to yours of the 29th ult., subject to equitable arrangements, through bookings and through workings would undoubtedly be to the advantage of everybody concerned.—Yours, etc.,

S. B. COTTRELL.
Engineer and Manager of the Liverpool Overhead Railway Company.

Digitized by Google

A corporation engineer who has gone fully into the matter, but who, for business reasons, does not wish his name to appear, writes as follows: "Personally, I think intercommunication ought to be arranged, but in making arrangements it should be borne in mind that the town authorities generally have by far the better portion of any joint system, and that it is, as a matter of fact, very much more to the advantage of an outside authority—where the traffic is necessarily lighter—to have the advantage of running into the centre of a dense population, and if the outside authority would view the matter in this light I think it is desirable to have intercommunication. At the same time I think far too much noise is made, probably with a view to besmirching municipalities, as to the importance of through cars, as if the two services are worked so that cars meet each other, and there is outward communication so that nobody need be left, there is not much difference between this and through running.

"I think in a county like Lancashire, where tramway authorities are fairly numerous, and are likely to join up to each other, that intercommunication between them will ultimately have to come, and I think any arrangements so made should be made by a joint Board, on which each of the tramway authorities concerned should be represented. An arrangement like this, as a matter of fact, now exists in Lancashire. For some time since the Liverpool tramway authorities called together the tramway authorities of Lancashire, and appointed a joint committee, together with representatives of the South Lancashire Tramways Company, for the purpose of arranging through running for goods traffic. As far as I know, this committee is still in existence, but owing to the arrangements at Liverpool being blocked by their not obtaining powers for taking over the Bootle Corporation system, the matter has been somewhat in abeyance."

Blackpool, Nov. 30.

Dear Sir,—Yours of the 29th inst. *re* above subject to hand, for which I am obliged. The question of intercommunication between two undertakings is a very difficult problem to give any general opinion on, as every case requires its own consideration as to whether it would be wise in the interests of the owners to have compulsory running powers forced upon them. Generally speaking, I am of opinion it is desirable to give the general public all the advantages possible in using the tramways whenever it is practicable to do so. As to terms upon which interchange of traffic should take place, this could only be arrived at after knowing what the conditions of the systems were.—Yours, etc., JOHN CAMERON,

Secretary and General Manager, Blackpool and Fleetwood Tramroad Company.

Dublin, Dec. 6, 1904.

Dear Sir,—Replying to your letter of 29th ult., I am strongly of opinion that compulsory interchange of traffic is neither practical nor desirable, but that same could be advantageously operated under a mutual agreement.—Yours, etc., R. S. TRESILIAN,

Secretary to the Dublin United Tramway Company.

Dublin, Dec. 6, 1904.

Dear Sir,—In reply to your favour of 29th ult., I am strongly in favour of compulsory running powers being obtained wherever practicable, and my chief regret in connection with this company is that owing to a difference of gauge we are unable to avail ourselves of through communication with the Dublin United Tramways. Our passengers complain of the change of car which is necessary, and I am convinced that traffic which would otherwise be secured is now lost.—Yours, etc., H. HARRISON,

Manager, Dublin and Lucan Electric Railway Company.

Norwich, Dec. 2, 1904.

Dear Sir,—In reply to yours of Nov. 29 *re* interchange of traffic on tramways. This is not a subject to which I have given very much attention, as there is no likelihood, at present, of the matter affecting these tramways, this system being quite isolated.

In a general way, however, I am very strongly of opinion that, in the interest of the public, wherever two systems connect, interchange of traffic, without change of cars, should be arranged. If the parties cannot come to an amicable arrangement, compulsory powers should be applied for.

In my opinion, the difficulties of such an interchange are very much over-rated. Of course, the terms of such interchange would have to be devised on the merits of the case in each particular instance. I do not see how any general rule could be made to apply to all.—Yours, etc.,

ALAN N. BANISTER, M.I.M.E., Engineer and Manager, Norwich Electric Tramways Company.

Scarborough, Nov. 30, 1904.

Dear Sir,—In reply to yours of the 29th, I think the question of intercommunication where practicable is an important one, and should be arranged by a mutual agreement, as at Leeds, and not a compulsory arrangement, as at Newcastle.—Yours faithfully, J. E EDMUNDSON,

Manager, Scarborough Tramways Company.

Guernsey, Nov. 30, 1904.

Dear Sir,—In reply to your letter of Nov. 29, I fear I am unable to give you any serviceable information dealing with the points raised, the local conditions being very different to those existing in England. I, however, consider that intercommunication upon tramway systems is not necessary, and if adopted would lead to very heavy staff charges due to the greatly increased clerical labour in all departments. I do not consider the suggestion of compulsory interchange of traffic at all a necessity or even desirable.—Yours, etc., ALBERT L. DAVIS.

Guernsey Railway Company, Limited.

Bushmills, Nov. 30, 1904.

Dear Sir,—In reply to yours of the 29th ult., the experience on our tramway will, of course, be different from what may be deemed advisable in relation to town tramways.

We have interchange of traffic with the railway company with which we adjoin, both for passengers and for parcels. I consider the interchange of traffic—*i.e.*, through bookings—desirable under certain restrictions, but certainly not compulsorily so, the accumulation of many different classes of tickets in a conductor's hand being objectionable, while by the establishment of suitable issuing offices through bookings could be arranged.—Yours truly,

WILLIAM A. TRAILL,

Managing Director, Giant's Causeway Electric Tramway.

Chatham, Dec. 1, 1904.

Dear Sir,—As requested in your favour of the 29th ult., I have pleasure in stating my views as follows: I am quite sure in a great many cases interchange of traffic is both practicable and desirable, but as for the terms, that must entirely depend upon mutual agreement, as local conditions vary so much that it would be impossible to lay down hard-and-fast rules. H. JENSEN,

Chatham and District Light Railways Company.

Bath, Dec. 1, 1904.

Dear Sir,—I am in receipt of your circular letter of the 29th ult. with reference to intercommunication between tramway systems.

Personally, I am very much in favour of interchange of traffic, and think that it can always be made practicable and desirable, but, of course, the terms would have to be gone into in each separate case. I am, however, in favour of through traffic, so that no changing cars is necessary for passengers.—Yours, etc., R. D. MCCARTER,

Manager and Engineer, Bath Electric Tramways, Limited.

Digitized by Google

GROUP III.—LETTERS FROM CORPORATION ENGINEERS AND MANAGERS.

Burton-upon-Trent, Dec. 3, 1904.

Dear Sir,—I am receipt of yours of the 29th ult. regarding the subject of intercommunication on tramway systems and parcel traffic. With reference to the former, I think that in many cases intercommunication is a mutual advantage to both tramway systems, and unquestionably a great public convenience.

I do not think that making this intercommunication compulsory is desirable; it should be more a matter of careful consideration and mutual arrangement between both parties. There are many technical and traffic points to be gone into before another system should be allowed to run over one's own system, and these should be amicably arranged instead of being compulsory.

In our case we are permitting the Burton and Ashby Light Railway to run over part of our track, so as to reach the centre of the town and the railway station. Their system comprises some 14 miles of track, and will bring the mining and pottery districts, having a population of about 40,000 or so, in close touch with Burton, this being the nearest largest town. This will unquestionably be a great convenience, and, it is hoped, of mutual interchange to both parties. The details as to how this advantage will take place have, however, not yet been settled.—Yours, etc.,

P. J. PRINGLE, Engineer and Manager,
Burton-upon-Trent Corporation Tramway.

Brighton, Dec. 2, 1904.

Dear Sir,—I have to acknowledge receipt of your letter of the 29th ult. with reference to the question of intercommunication between tramway systems. Personally, my views are that it is very desirable that intercommunication should be afforded, but I do not agree that compulsory interchange is desirable, but that in all cases it should be left to a matter of arrangement by agreement, as no doubt there would be special matters in connection with each special system that could only best be settled by mutual agreement.—Yours faithfully,

THOMAS B. HOLLIDAY, Tramways Engineer and General Manager, Brighton Corporation Tramways.

Barking, Essex, Nov. 30, 1904.

Dear Sir,—In reply to your letter of the 29th, my views *re* inter-running entirely coincide with those of Mr. Stephen Sellon, whose paper is being read to-morrow night on inter-running before the Tramways and Light Railways Association. I am entirely of opinion that in the interests of the public inter-running between neighbouring authorities, if unable to be arranged by agreement, should be arranged by compulsion. I am glad to say that in our case, between Barking, Ilford, East Ham, and West Ham, we are arranging through running on perfectly amicable lines, although the agreements are not drawn up at present.

I consider that the interchange of traffic is generally practicable, and most desirable, but the terms upon which such interchange should be arranged are affected entirely by the local conditions, and I do not see that it is possible to lay down a hard-and-fast rule.—Yours faithfully,

A. HUGH SEABROOK, Engineer and Manager,
Barking Urban District Council Tramways.

Hull, Nov. 30, 1904.

Dear Sir,—I have your letter *re* intercommunication and goods carrying. Regarding the first, we in Hull are in a position of isolation, as there is no tramway system within many miles of us; therefore, we are not called upon to face the question from an individual standpoint. So far as the broad principle of interchange of traffic is concerned, the convenience of tramway riders is the first consideration. This being so, it appears to me in the highest degree desirable that tramway authorities should set themselves, wherever possible, to adjust matters so that the public may reap whatever benefit may reside in facilities for intercommunication. A company or a corporation cannot take up a recalcitrant attitude, and in effect say to the public, "We can run cars to suit you, and give you the facilities you require; but to do so doesn't suit us, because such and such a thing stands in the way." Public opinion would not stand that sort of thing, and there is no doubt the Legislature would step in and summarily adjust the differences between the authorities. There appears to be such a spirit of compromise abroad that it is hardly likely that drastic measures will have to be employed in settling matters in dispute.

Re the question of terms, this, of course, is a matter to be settled upon the merits of the case, and no one could lay down a hard-and-fast line as to particulars.—Yours, etc., WILLIAM J. MCCOMBE, Manager,
Corporation of Kingston-upon-Hull Tramways.

Ipswich, Dec. 2, 1904.

Dear Sir,—In reply to your letter of the 29th inst., the question of intercommunication hardly concerns me at present, as Ipswich is so isolated from all other towns which have, or could have, tramways. Speaking generally, however, I should say that the public convenience should be the first consideration both with companies and corporations owning tramway systems, except in those cases where it is apparent that catering to the public convenience will entail a dead loss on the revenue account. I think, however, that it is generally found that the greater the effort made to meet the convenience of the public, the more popular is the system and the greater its success financially. On these grounds I should say that the interchange of traffic between different systems is most desirable where possible.—Yours, etc., FRANK AYTON, Engineer and Manager,
Ipswich Corporation Tramways.

Colchester, Nov. 30, 1904.

Dear Sir,—Referring to your letter of yesterday, I am of opinion that compulsory interchange of traffic where practicable and desirable should be common to tramways. The difficulty is as to terms, but why should there not be a clearing house as on railways? I have had 20 years' experience on one of the leading railways in this country, and I remember the time when this difficulty was thought to be insurmountable on railways. Through running is now general on all railways, and I do not see why it should not be the same on tramways adjoining each other.—Yours, etc., R. C. BULLOUGH, General Manager and Engineer,
Colchester Corporation Tramways.

Shipley, Dec. 7, 1904.

Dear Sir,—With reference to your enquiry of Nov. 29, I have to say that the Shipley Council have leased their lines to the neighbouring authority of Bradford, who now control the entire system both of the city and the out-districts. The Corporation pay adequate interest on capital outlay, and they also pay a charge for maintenance. So far as the limited experience in this district goes, it seems to show that the principle we have adopted is much better than the one of interchange of traffic.—Yours faithfully,

I. LINDOW,
Clerk, Shipley Urban District Council.

THE PREDETERMINATION OF THE DEMAND FOR ELECTRIC LIGHTING IN MODERATE-SIZED TOWNS.

In an article by F. Erens in a recent number of the *Elektrotechnische Zeitschrift* an interesting connection between the demand for electric lighting in a given town and the prosperity of its inhabitants is shown to exist, at least in the case of certain moderate-sized German towns. The writer, being confronted with the problem of deciding beforehand the probable lighting output required by a town of 60,000 inhabitants, attempted to obtain an average figure by investigating the records of numerous other towns. He found, however, that, taking the 1902 statistics of German towns having between 30,000 and 150,000 inhabitants, the results differed very decidedly, the extreme values being

Digitized by Google

respectively 3 kw. and 25 kw. per 1,000 inhabitants. The higher values might be due to the high price of gas lighting, the low price of electricity, to special expedients employed by the station engineers or to general economical conditions, and in order to arrive at some satisfactory explanation a circular letter was addressed to the authorities of 10 of the towns which, in spite of a comparatively short time of service, had attained very high values for the lighting output. In this letter special enquiry was made as to the causes of the high values, and as to any special means adopted for raising the value. The replies showed that the price of gas in these towns was in no way unusual as compared with that of electricity. The authorities also placed little weight on the special means adopted (which consisted chiefly in the free installation of houses or their installation under easily fulfilled conditions), but all agreed that the chief cause of the high value lay in the financial condition or prosperity of the inhabitants.

In order to investigate this point, the writer assumed that the prosperity of the inhabitants was proportional to the income tax per head paid to the State. This assumption is only correct when all the towns are taxed under a uniform law and on the whole of the incomes, and these conditions

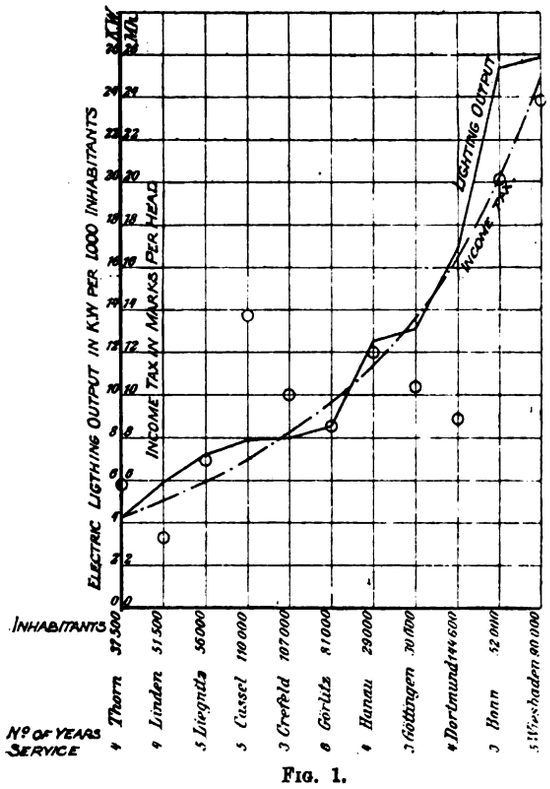

FIG. 1.

applied to the Prussian towns alone. As, besides this, all towns of more than 150,000 or less than 30,000 inhabitants, as well as towns with very widely differing lengths of service, had to be excluded, the comparison could only be applied to a small number of towns. In the curve (Fig. 1) the towns are arranged so as to form a rising curve of kilowatts per 1,000 inhabitants (shown by the angular solid line), and the values of the income tax in marks (shillings) per head are shown to the same scale of ordinates by the small circles. The dotted line is the approximate average for these circles. It will be seen that the one curve practically lies over the other, so that the two following conclusions may be drawn: (1) the prosperity of the inhabitants of a town is a measure of the electric lighting output; (2) the value in marks of the income tax per head under the Prussian law is, in the case of medium-sized towns, approximately equal to the kilowatts per 1,000 inhabitants used in electric lighting after five or six years' service. The latter rule, of course, cannot claim to represent the facts exactly, but the curves given may be of some service in deciding the probable relative values of the electric lighting outputs in different towns.

Diary.—Particulars of the "Practical Engineer" Electrical Pocket-Book and Diary for 1905 appear in another column.

NOTES ON PERMANENT WAY FOR TRAMWAYS.*

BY A. N. CONNETT, M I C E (MEMBER OF COUNCIL).

This subject may be somewhat hackneyed, but no one interested in tramways would be inclined to question its importance. Much has been written with advantage on the permanent way of steam roads without exhausting the subject. Considering the large capital invested in tramways, and the importance in both first cost and upkeep of the permanent way, no apology is necessary in submitting the results of observation and experience in the hope that some increase, however small, may be added to the common stock of knowledge. The variations in the first cost of permanent way are wide. This is largely due to differences in paving requirements. The figures for new track vary in general from £4,000 to £6,000 per mile of single line. There is naturally a wide variation in the proportion of cost of the various items entering into completed track, due to local or special requirements. The following analysis of proportionate costs will be found to be a fair general average for new lines: rails and fastenings, 22; special work, 10; paving material, 30; cement, sand, and broken stone, 14; labour, 15; bonds, 2; and cartage and miscellaneous, 7 per cent.

Rails.—One result of the report of the Standardising Committee on tramway rails has been to cut out an important amount of "copy" in articles such as this. The necessity of standardisation has been amply demonstrated by the unanimity with which the recommendations of the committee were adopted. The advantages, both to buyer and seller, are so evident in this instance that it is to be hoped that the principle may be carried further than is now contemplated.

I have no desire to say anything about the standard sections further than that I think them admirable, having regard to the conditions imposed upon tramways in this country. I am not, however, an advocate of too rigid an adherence to the specifications suggested by the committee; not but that they may be quite correct when properly interpreted—as a layman I would not suggest otherwise. The experts on the Continent differ from their brethren in Great Britain and the United States in that they consider that the physical tests show sufficiently whether the product is fit for its intended use, and they, therefore, limit themselves to such tests, leaving to the manufacturer a free hand in other respects. There is a risk that the engineer, who cannot always be expected to be an expert in metallurgy, may specify chemical requirements inconsistent with the physical tests. Again, the product may pass satisfactorily the required physical tests, but depart from specified limits in one or more comparatively unimportant elements in the chemical analysis. No particular harm should arise in any such case if the question is left to the discretion of the engineer for decision, but a municipal engineer may regard it as his duty to bring such a matter before his committee for settlement. It is needless to say that there is not one chance in a thousand that the committee would be in any way competent to consider, let alone decide, such a question.

An experience of this kind proved, to my satisfaction at least, that such a case can arise. In this instance the net result was a large increase in my knowledge of the effect of silicon in steel, and also to provide me with what my friends are pleased to call "a good story." But the case had potentially very serious possibilities. The result of the efforts of the Standardising Committee has made improbable for a long time to come changes in the sections of tramway rails of the ordinary girder type; still, this does not mean that finality has been reached in the design of tramrails. Many types of rails have been designed, and a number actually made and used. Some few have had a fair amount of success, but mostly they have turned out dismal failures. It is not stating the case too broadly to say that, all things considered, none of these have proved superior (and it is even disputable if any one has proved equal) to the ordinary well-designed girder tramrail.

Joints.—The question of joints is truly a difficult one. On no other detail of permanent way has so much thought

* Paper read before the Tramways and Light Railways Association

Digitized by Google

been expended. It is well recognised that the life of the rails is limited by the wear at the joints. It certainly does not make for confidence in the economic future of electric tramways to see rails which should have many years' wear in them taken out and replaced by new ones, simply because they are battered down at the joints. It is well known that the greatest enthusiasts on the joint problem, apart from those who have joints to sell, are those having had the least experience. The more one has had to do with the problem, the less one feels on safe ground in recommending anything. All are familiar with the optimistic saying about a well-known stimulant; reversing this, the experienced tramway engineer is tempted to say that all joints are bad, only some are worse than others. If the experience gained on steam roads was more directly applicable to tramways, the tramway engineer would be a great gainer thereby, but the conditions differ to such an extent that, after giving due regard to the results of railway practice, the tramway engineer finds that his own problem is still far from solution.

When the permanent-way construction consists of rails laid on sleepers with ballast foundation, the tramway engineer may feel justified in adopting a splice-bar joint, either of the ordinary type or combined with some such feature as the continuous joint gives. Such a permanent way is at least fairly comparable with that of steam railways. If the sett paving is laid with sand joints, it is not a very expensive matter to have access to the joints when they need repairs. Such conditions largely exist in the United States. In this country the requirement of a concrete base for paving, with the setts laid almost directly on the base, makes the construction as above outlined hardly admissible. Having given a foundation of artificial stone, what more natural than to lay the rails directly thereon? Most of the tramway construction has been so made, and there seems to be marked tendency to depart therefrom. The conditions existing in permanent way so constructed must of necessity differ widely from those found with the elastic road-bed of a steam railway. For example, the wave motion which is so well known in railway practice must be, if not practically absent, at least much modified with the continuous rigid foundation of a tramline. There is thus no necessity for a tramway engineer to give much consideration to the possible bad effect of unduly stiffening the joint on account of prejudicially affecting the continuity of the "wave." On the other hand, the tramway engineer has a serious condition to meet that the railway engineer has not, in that the tram joint is inaccessible for inspection and repairs. This in reality is the vital difference. If tramway joints could have the same attention that they have on steam roads, the joint problem would have about the same relative importance in the one case as in the other.

Disregarding for the moment any other than mechanical joints, it will be found that splice bars of special form, or ordinary bars used in conjunction with some other device, form the great majority of joints, patented or otherwise. Therefore it is quite proper to give due consideration to the ordinary splice bar. A well-designed bar should have the following features: (1) Large area of bearing surface at top and bottom. The load from one rail to the other being transmitted by the joint, it is evident that this load should be distributed over a large bearing surface. (2) The maximum thickness of bar that circumstances will permit. Having given a determined depth of rail, the stiffness of the bar to resist flexure can only be increased by added thickness. It is, of course, evident that the stiffness is immensely increased by adding to the depth of the bar. This would explain why the ordinary form of fishplate has been so successful with the deep rails used in America. The thickness of metal also prevents deformation of the bar by the bolts. (3) The vertical member of the bar slightly convex in relation to the web of the rail. The advantage of this is twofold. It prevents the bar from being drawn inwards from the vertical position by the effect of tightening the bolts, and it also permits the use of concealed bonds. (4) A clear theoretical distance of from $\frac{1}{2}$in. to $\frac{3}{4}$in. on the fishing surface of the rail, top and bottom, to be left after the bars are finally fixed in place. This allows for slight inequalities in the rollings without destroying the fishing effect, and also permits taking up the wear which occurs in service on the flat fishing surfaces of rails and bars. (5) Long splice bars, say between the limits of 26in. to 32in. The great wear of the fishing surfaces of rail and splice bar appears in that portion near the joint. It is, therefore, of little practical utility to make the bars of an abnormal length. Personally I believe that 26in. is, all things considered, about the right length. This permits a good distribution for six bolts. The engineer should make rigid requirements in his specifications for accurate fit between the bars and the rails, and see that such are carried out by the manufacturers.

A well-designed and well-rolled splice bar may lose a large part of its efficiency if proper precautions are not taken in the fixing. It is evident that looseness or play between the bearing surfaces of the bars and the rails will have for effect a prejudicial "pounding" action at the joint. However small this may be at first, the continued shocks rapidly increase the wear between the surfaces, so that the trouble grows at a most alarming rate. It is clear, therefore, that nothing must intervene to prevent the best bearing possible between rails and bars. To accomplish this, the bearing surface of the rails should be thoroughly cleaned of rust and scale by using a hand hammer and file. If the splice bars have been dipped, the compound should be removed from the bearing surfaces in some suitable way. The splice bars should be put on "square," and at first only drawn up sufficiently to hold the rail snugly together. After the rails are surfaced, the bolts should be drawn up tightly, using not less than a 2ft. spanner, and at the same time tapping the head with a light hammer. As a final precaution, the bolts should be gone over in the same way, just ahead of the paving work.

The ordinary splice-bar joint, designed, made, and fixed in the manner above outlined, will give results far better than is generally believed. From experience, I feel safe in saying that such joints will give excellent service, provided they are opened up and refixed once a year. It is too often the case that the joints are not attended to until they are "pounding" badly. The result is permanent injury to the rail heads, and possibly a "set" in the splice bars. The repairs when undertaken are often limited to taking out a few setts and tightening up the bolts. It is forgotten that the bearing surfaces are not machined, and that the bars and rails fit only on the high places, so to speak. In consequence there is wear and actual abrasion of the bearing surfaces, the first effect of which is a slight "pound" at the joint. To make the repairs anything like effective, the splice bars should be removed, the bearing surfaces of bars and rails thoroughly cleaned, and the bars put back with the utmost care and attention. This is the reason why small boxes about the joints, which only permitted access to the bolts, were found to be of such doubtful utility. If boxes are provided, they should be designed with the object of permitting the removal and replacement of the bars.

The cost of repairs to such joints, including taking out paving, refixing plates, and reinstatement, should vary from 3s. to 4s. per joint. If 60ft. rails are used, the number of joints will average, say, 190 per mile of single line. The cost then will vary between £30 and £40 per annum. A common form of joint is a soleplate, riveted or bolted to the base of the rail in conjunction with the ordinary fishplates. Such a plate, if used alone, would be of little use to transmit the load from one rail to another. In consequence, the chief reliance must be placed on the splice bars. The joint known as the "continuous rail joint" has been extensively used with excellent results. It is in effect a soleplate joint without the bolts or rivets.

What is called the "anchor" joint is very largely used in this country. This type of joint might with advantage be called "girder soleplate" joint, the anchoring feature being merely incidental. Usually a piece of the rail is used, though any ordinary girder section answers quite as well. Such a construction has been used on steam roads, where it was called a "crop end" joint. It was found to give a stiff joint, so stiff, in fact, that it was a question whether the rails did not wear more from this cause than they would have with the ordinary flexible angle bar joint. This objection can have little weight for tramrails laid continuously

Digitized by Google

on an unyielding concrete foundation. Such a joint should be of considerable assistance to prevent the initial loosening and consequent refixing, but wear will occur between bottom of the rail and the top surface of the girder soleplate. The experience gained by putting joints on extended yoke seats in cable railway construction demonstrated conclusively that such wear does occur. When once looseness at the joint commences, the subsequent maintenance of a good joint will depend upon the splice bars. Whether the presence of a stiff girder soleplate will affect the refixing of the splice bars to get a good joint I am unable to state, having had no personal experience to guide me.

In fixing the joint above described, it is necessary to take the precaution of careful examination of the rail heads. The slightest difference in level in the two abutting rails will cause "pounding"; the rail ends, consequently, should be filed or ground off, wherever necessary, before the tracks are used for car service. Many other forms of mechanical joints have been tried. Too many of these have some fancied advantage which necessitates sacrifice of one or more good features of the splice bars, the net result of which is prejudicial rather than otherwise. Scarfed or bevelled joints have been quite extensively tried on the Continent. If there is any advantage in these, it must be on the principle that the wheel drops into the space between the rails when the joint is square. How slight the drop is may be seen from the example of a 30in. wheel and a $\frac{1}{4}$in. joint, the drop in this case being less than $\frac{1}{1000}$in. If joints were damaged from this cause, the rail ends should be "battered." An examination of the rail heads at worn joints will quite invariably show a bright or battered spot an inch or more from the gap between the rails. On double lines the direction of travel of the cars can be determined by the relative position of this worn or bright spot, it being found on the entering and not the leaving side of the joint. This would indicate that the wheel jumps before arriving at the gap between the rails, and that this is due to flexure at the joint. It would appear, then, that the scarfing or bevelling of rail ends can have no beneficial effect. There is a class of joint quite distinct from these already considered which comes under the general head of "welded" joints. This class again subdivides into cast weld, electric weld, and thermit weld.

Cast Weld Joint.—This process was first exploited by the Falk Manufacturing Company, Milwaukee, U.S.A. Many thousands of these joints have been made with varying success. If the joints are made in the most careful manner by an experienced force under a capable superintendent, they are generally successful. It has been stated that the process of welding by using a large mass of molten metal changes the character of the steel rail ends, and that there is, in consequence, wear at the joints due to softer steel there than elsewhere. I had a large experience with this type of joint in France. The results, so far as I could judge, were satisfactory. The most serious objection is the plant required. It is expensive and most difficult to handle. The transportation and use of a miniature blast furnace along a public road is a thing one would avoid if possible.

Electric Weld Joint.—This process was at first a failure, but the determined confidence of the Lorain Steel Company has finally been rewarded with success. It is now being tried on a number of important lines in this country. It, however, has also the disadvantage of requiring formidable plant.

Thermit Weld Joint.—This joint, due to Dr. Goldsmith's alumino-thermit process, is the latest arrival in the field of welded joints. The chemistry of the process and the manner of its application to rail joints have been thoroughly described in the pamphlets of the company and in the technical Press. It has been tried in a number of places in this country, the most notable example being Leeds. The tramway engineer there appears to be thoroughly satisfied with the joints. The plant is quite a simple one, and in this respect there is a decided advantage over the other forms of welded joint, both in the case of first application and of subsequent repairs. If the present favourable indications are borne out by future results, it is not too much to say that welded joints will be largely used hereafter. In the case of new lines the engineer has to have implicit confidence in the joint, because, if failure results, he has ruined the rail ends for the application afterwards of any mechanical joint. In an old track, where the rail ends are worn out at the joint, the case is quite different—one can then afford to take a risk. With all forms of welded joints the work must be done well by an experienced man. Bad workmanship with mechanical joints is capable of rectification, but this is not true with welded joints. My experience has been that the process of welding limits materially the amount of line which can be laid by the platelaying gang, and therefore the progress of the work is determined by the rate of laying such joints. Personally, I believe in paving the track, except around the joints, using fishplates temporarily, and then welding the joints afterwards. In this way one can overcome in the safest manner the effects of expansion due to the heating of the rails at the weld.

Special Work.—There has been a notable advance in the past three years in the ideas of engineers as to the type of special work best suited to tramway requirements. Short castings with "baby" tongues and primitive arrangements for fishing the joints are being replaced on most work by much more suitable types. Long points, from 11ft. to 13ft. over all, are now being generally used, the tongue having a length of about 7ft. The tongues should be invariably curved on the curved side. The body of the casting is either of ordinary cast steel or manganese steel. The difficulty with both is to get a good joint with the abutting rail section. It is almost hopeless to expect to get as good a joint here as elsewhere on the track. The consequence is that these joints fail before the others. It is questionable, then, why such material as manganese steel should be used for the body of the casting. Outside of the joints, the real wear takes place on the tongue. These are made of annealed cast steel, manganese steel, or forgings. Either of the former will wear longer than the last-mentioned, but the cast tongues have the disadvantage of breaking more frequently from flaws or blowholes.

At all facing points, where the cars will take either one or another direction, it is preferable to use one tongue and one blind point. In this manner all mechanism is avoided to connect the two tongues, and pointsmen can be dispensed with. All that is necessary is to have a hooked end rod hung over the front dasher. The motorman stops over the points and unhooks the rod, which has a flat rectangular piece welded on its lower end. He can throw the tongue in an instant and resume his journey. The economy in dispensing with pointsmen will be perfectly evident to tramway managers. The blind point is designed with an inset piece to give it a long life. Even if it does not give as great a life as a double-tongue arrangement, certainly the difference will not by any means compensate for the outlay in providing pointsmen.

Crossings should by all means be of the well-known "iron-bound" type, with hardened inset placed at the junction of the grooves. This construction permits of as good a joint being made at each end of the crossing as elsewhere on the track. It is possible that in practice it will not be found feasible to renew the hardened wearing piece; nevertheless, it will give in itself a much longer life to the crossing, and should invariably be a part of the same. If, when it wears out, it can be successfully replaced by another one, so much the better. There is too great a tendency for these inset pieces to shake slightly loose after being in service but a comparatively short time. Manufacturers should pay great attention to overcome this defect. The raised floor of the hardened piece should be bevelled at the ends, but, nevertheless, so designed that its height from the rail head is the same as that of a new wheel flange. In this way the jolt to the car which is so often felt at the crossings will be avoided.

On any tramway system there is no necessity to have more than one radius for the points even for lay-outs. Immediately beyond the point the curve can be compounded into a greater or less radius, if necessary. This will mean that there will be only four patterns in use on any system, assuming that no double-curved tongues are used. For cross-over roads and turn-outs, standard angle crossings need only be used. If there could be some uniformity in

Digitized by Google

the types of points and crossings used generally in the country, it would be of very material advantage. These could then be made up and kept in stock by the manufacturers, and construction work could be proceeded with in a much more satisfactory manner than at present. It is a well-known fact that in almost every case the date of completion of permanent-way work is dependent upon the delivery of special track work.

Of course, there can be no uniformity in the crossings of special lay-outs at junctions. On most tramway jobs, however, the greater portion of the special work occurs in turn-outs and cross-over roads, and if these can be had promptly the junction work can be manufactured during the construction period, so that they can be put in towards the last, and in this way the time of completion of the whole job materially hastened. If the type of iron-bound crossings is generally adopted, manufacturers can at any rate keep in stock the standard British sections, so that these can be put in hand without waiting for the rolling of rails for any particular piece of work.

Curves.—The wear of rail at curves is quite a serious matter in lines where the car traffic is heavy and the curvature considerable. A due consideration of how the wear is produced may not be inappropriate. Wellington, in his well-known work on railroad location, made an analysis of the problem, from which most of what follows is taken. If the rear wheels of the truck have no flanges, the rear axle would assume a radial position, and consequently the wheels would leave the rails, taking a place inside of the curve, the amount of which would vary inversely with the radius, and directly with the wheel base. On railways with bogie trucks and large radius curves, the rear axle does take this radial position, but with tramways where the radius of the curve is so small, comparatively speaking, the distance that the rail wheels tend to stand away from the rails is much greater than the play of the gauge; therefore the rear axle is prevented from taking its natural position, and in consequence the axle takes a position parallel to a radius drawn to the centre of the truck. In the case of the tramway truck, there is therefore a certain wear on the rear wheel flanges, and consequently on the rails also, due to the effort to keep the rear wheels on the rails. This wear is inversely proportionate to the radius of the curve, but is not considerable, because the displacement from the natural position of the wheels is not great, and the centrifugal force of the car on the curve acts in the contrary sense, thereby tending to diminish this wear. The real work in pushing the wheels laterally from the straight line direction, where they naturally roll, is performed by the front inner wheel. If the axles could assume the radial position the wear would be slight, but the angular position of wheel and rail, which increases with the wheel base and with the sharpness of the curve, produces rubbing friction between rail and flange. If the wheel base is short, practically the whole work will be performed by the inner front wheel. With long wheel base the rear outer wheel will do a portion of this work—*i.e.*, the total amount of the work will be greater, but the distribution of the wear will be better. Of course, there is a limit in length of wheel base, which, if exceeded, will not permit the flanges to enter the groove in the angular position of the wheel with respect to the groove. A section should be made of the proposed flange in the minimum curve, in the angular position determined by the wheel base, to see that the flange will roll in the groove. If it does not, the wheel base must be shortened, or the flange made narrower. This is not a plea for long wheel bases, but only an effort to show that, within certain well-defined limits, they are not so prejudicial as is generally supposed.

In a paper recently read, it was shown that bogie cars of the maximum traction type have a largely increased current consumption for about the same carrying capacity car body. The statement was made that the test conditions were favourable to the bogie cars in that the route had an excessive amount of curvature. I believe, on the contrary, that the difference would not have been so marked on a straight route. With the bogie truck, the flange and rail has to overcome the friction of the centre plate for pivotal trucks, and for maximum traction trucks, the very serious side-plate friction.

The experiment above referred to was made with side-bearing maximum traction trucks against single trucks. If centre pivotal trucks had been used, in all probability the difference in current consumption would not have been so great. I know of an instance where single and maximum traction trucks are used, and where the wear of flanges and curve rails is excessive. This is attributed to the single trucks, because the wheel base is 7ft. I believe, on the contrary, that the maximum traction trucks are the worst offenders.

(To be continued.)

FORTHCOMING EVENTS.

FRIDAY, DEC. 9.

Electro-Harmonic Society.—At 8 p.m., smoking concert.

Northampton Institute.—(And Saturday). At 6.30 p.m., prize distribution and conversazione.

Physical Society.—At 8 p.m., at the Central Technical Institute, "On Rapid Method of Approximate Harmonic Analysis," by Prof. S. P. Thompson; "A High-Frequency Alternator," by Mr. W. Duddell; experiments to show the retardation of the signalling current on 3,500 miles of the Pacific cable between Vancouver and Fanning Island; exhibition of Ayrton-Mather galvanometers, universal shunts, and electrostatic instruments.

SATURDAY, DEC. 10.

Junior Institution of Engineers.—At 3 p.m., visit to the International Gas Exhibition at Earl's Court.

Corps of Electrical Engineers (R.V.)—At 7.30 p.m., annual mess dinner at Anderton's Hotel.

Glasgow Technical College.—At 7.30 p.m., "Electro-Metallurgy—Some Notes on its Present Position," by Mr. J. D. Mackenzie.

Birmingham and District Electric Club.—At 7.30 p.m., inaugural address by the president.

MONDAY, DEC. 12.

Institution of Mechanical Engineers (Graduates' Section).—"Gas-Engine Testing," by Mr. A. C. Hess.

Institution of Electrical Engineers (Newcastle Section).—"Batteries with Reversible Boosters," by Mr. C. Turnbull.

TUESDAY, DEC. 13.

Institution of Electrical Engineers (Manchester Section).—At 7.30 p.m., "High-Tension Switchgear," by Mr. L. Andrews.

Institution of Electrical Engineers (Glasgow Section).—At 8 p.m., "Armature Reaction in Alternators," by Mr. J. B. Henderson and Mr. J. S. Nicholson.

Metropolitan Railway.—Run from Baker-street to Uxbridge and back.

Institution of Civil Engineers.—At 8 p.m. "The Construction of a Concrete Railway Viaduct," by Mr. A. Wood-Hill and Mr. E. D. Pain.

WEDNESDAY, DEC. 14.

Society of Arts.—At 8 p.m., "The Patent Laws," by Mr. Chas. D. Abel.

Institution of Electrical Engineers (Birmingham Local Section).—At 7.30 p.m., "Stand-by Charges and Motor Load Development," by Mr. A. M. Taylor.

Society of Engineers.—At 7 p.m., annual dinner at the Hotel Cecil.

Chemical Society.—At 5.30 p.m., general meeting.

THURSDAY, DEC. 15.

Institution of Electrical Engineers.—At 8 p.m., continuation of discussion on Mr. Searle's paper, "Studies in Magnetic Testing." Mr. W. P. Adams will read (time permitting) a paper entitled "The Combination of Dust Destructors and Electricity Works economically considered."

Rugby Engineering Society.—At 8 p.m., discussion on "Premium System v. Piecework System," to be opened by Messrs. G. T. Wood and J. P. S. Glover.

FRIDAY, DEC. 16.

Institution of Mechanical Engineers.—At 8 p.m., "Heat Treatment Experiments with Chrome-Vanadium Steel," by Captain H. R. Sankey and Mr. J. Kent-Smith. Messrs. Seaton and Jude's paper on "Impact Tests on the Wrought Steels of Commerce," which was read at the last meeting, will be further discussed jointly with the above paper.

North-East Coast Institution of Engineers and Shipbuilders.—General meeting.

Institution of Electrical Engineers (Manchester Students' Section).—At 7.30 p.m., "The Working of Batteries under Reversible-Booster Control," by Mr. E. D. S. Shelmerdine.

Institution of Civil Engineers.—At 8 p.m., students' meeting, "Folkestone Harbour: Cylinder-Sinking at the Root of the Old Pier," by Mr. R. H. L. Pennell.

SATURDAY, DEC. 17.

Glasgow Technical College.—Anniversary dinner.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

TRAMWAYS—THROUGH RUNNING.

At the first blush the question of through running on tramway systems seems simple, and the answer to be in the affirmative, yet in practice experts do not find the solution of the difficulties so very simple. It is, perhaps, a peculiar situation for us to deal with, who for years have advocated every increase of convenience possible for the travelling public and the necessities of the business public. We have shown that in railway work increased convenience has been consistently followed by increased receipts and by a more pronounced success. Further, the advocates of the electrification of tramways have used as their main argument the undisputed and indisputable fact that such a measure has always been followed by increased receipts—receipts in most cases more than sufficient to warrant the outlay incurred by the change over. Electrification meant increased convenience, and the response of the public has usually been very marked. Through running undoubtedly means increased convenience; hence, as we say, at first sight it would appear a welcome development. There is no mental reservation in our remarks, nor is there any intention to deprecate the action of anybody. The simplification of railway through running is due to the fact that companies have to deal with companies. Each concern is controlled by business men, who have only one object—the success of their own company. When tramways are considered, we have a mixture of municipal and company control, and the ultimate aim of each party may differ very considerably. It is easy to assume conditions which almost prevent any solution of the problem when the parties are municipal and companies, and when the parties are both or all municipal, local jealousies are often worse to arrange than in the majority of cases where antagonism is direct. It was unfortunate that the Institution dinner clashed with the discussion on Mr. Sellon's paper, for the subject merits the fullest consideration. We welcome the specific examples of the value of through running given by Mr. Sellon, especially as they go to prove a point we have insisted upon for many years. Interurban communication—like water distribution and similar problems—to be dealt with satisfactorily, must be dealt with over the whole natural area by one combined authority, and not merely over the isolated portions termed boroughs or urban districts, or what not. What an absurdity it seems in these early days of the twentieth century that conterminous tramways have different gauges, the differences being almost entirely due to the desire of one or the other control to prevent through running. In such cases no attempt was made to consider the convenience of the user. We are not now discussing the desirability to have tramways at all at a particular spot. We assume they are there, and agree with Mr. Sellon "it ought not to be tolerated that parties entrusted by Parliament with tramway powers should be permitted by unreasonable conduct to prevent or hinder the full public use and advantage of any means of connection," always provided the different undertakings are honestly undertaken. It would be an intolerable nuisance if Parliament were to give "compulsory" powers to a concern with a mile of line, and with a capital of ten thousand pounds, claiming connection with one or two undertakings with a hundred times the mileage and the capital. When a railway projects an extension or a new system, the expenditure and return are duly considered upon a purely business footing, but this cannot be altogether the case with tramways, because of conflicting local interests. Mr. Sellon's paper gives a mass of information, and compares railway management, but the two things are not on

Digitized by Google

all fours; hence, if running powers are contemplated, it will be better to thrash out the whole question of division of receipts per car mile or per passenger from the conditions prevailing on tramways, and not assume them too similar to those prevailing on railways. In consideration of the importance of this question we have endeavoured to ascertain the opinions generally of those most interested, and the series of letters and extracts given elsewhere will show the prevailing idea to be for the extension of running powers.

THE CHAIR OF ELECTRICAL ENGINEERING AT THE BIRMINGHAM UNIVERSITY.

Appointment of Mr. Gisbert Kapp, M.I.C.E., M.I.E.E.

We congratulate the council of the University of Birmingham on their appointment of Mr. Gisbert Kapp to the above appointment. Every electrical engineer who has the pleasure of knowing Mr. Kapp will approve of his selection to this position, and will agree that he fully meets the many and onerous qualifications for the post. We are pleased that it will be the means of bringing back to England a man who ranked so highly amongst the pioneers of electrical engineering. When Mr. Kapp left England in 1895 to become the general secretary of the Verband Deutscher Elektrotechniker, it was felt that the profession was losing one of its best men, and his welcome back to this country will be a warm one. According to the terms of the appointment, we shall see Mr. Kapp again practising as a consulting engineer amongst us. As far as the Birmingham University is concerned, Mr. Kapp's organising skill, coupled with his cosmopolitan electrical experience, renders the success of his department assured. It will be difficult, however, to attach the title of "Professor" to one who for so long has led us in the practical side of electrical engineering.

NOTES ON MOTOR-STARTING SWITCHES.

[CONTRIBUTED.]

(*Concluded from page 803.*)

While in hotels, clubs, and other public buildings it is necessary to have a lift attendant always present for working the hoist, yet in many private works this course is not adopted, and it is then desirable to arrange a form of control by which the lift can be operated from any floor, while at the same time, if any person is travelling in the lift, it shall be impossible for anyone outside to control the lift in an opposite direction. The Sturtevant Engineering Company provide for such cases with their push-button lift controller, shown in Fig. 16. Suppose that the lift travels between six floors, then inside the cage are placed six push buttons, numbered respectively for the various floors, and there is also fixed inside the cage an extra push button, known as the "emergency button." Outside the lift on each floor is fixed a push button. It will be noted from the illustration that the control is effected in reality by a form of compound solenoid switch. Anyone wishing to use the lift will push the button on the floor on which he happens to be, when the controller will start the motor in the direction necessary to bring the cage to that floor; and also, as soon as the cage reaches the floor in question, the controller will cut off the supply of current, and the cage will come to rest. After the passenger has entered the cage, he will push the button corresponding to the floor to which he desires to travel. This will operate the controller so that the car will travel only to the floor desired, where it will stop; while at the same time it will be impossible, until the car has reached this floor, for the cage to be operated by anyone outside the car. Should the passenger find that he wishes to stop at an intermediate floor, he has only to push the emergency button, for if he does this the car will stop at once, whether at a floor or between two floors, for the result of pushing this button will cause the controller to cut the current off the motor, and also off the brake solenoid, thus bringing the car to an immediate standstill.

It would appear possible from the above description for an accident to occur through a person on some other floor starting the car when the passenger was either entering or leaving the cage. To prevent this, the apparatus is so arranged that it is impossible to operate the controller when any one of the lift gates is open. This entails the necessity of so arranging the gates that each is automatically locked except when the car is directly opposite to it.

A study of the illustration will enable the method of operation to be readily grasped. The controller is, first, a form of the ordinary solenoidal starting switch previously described. In addition to this, there are the supplementary solenoids—one for each floor. These are so connected with the reversing switch as to provide the correct direction of rotation, and as the button marked No. 1 in the car is connected with the leads from the button on No. 1 floor, and the button No. 2 is connected to the leads from the button on No 2 floor, exactly the same effect is produced whether the button on No. 1 floor or the button marked No. 1 in

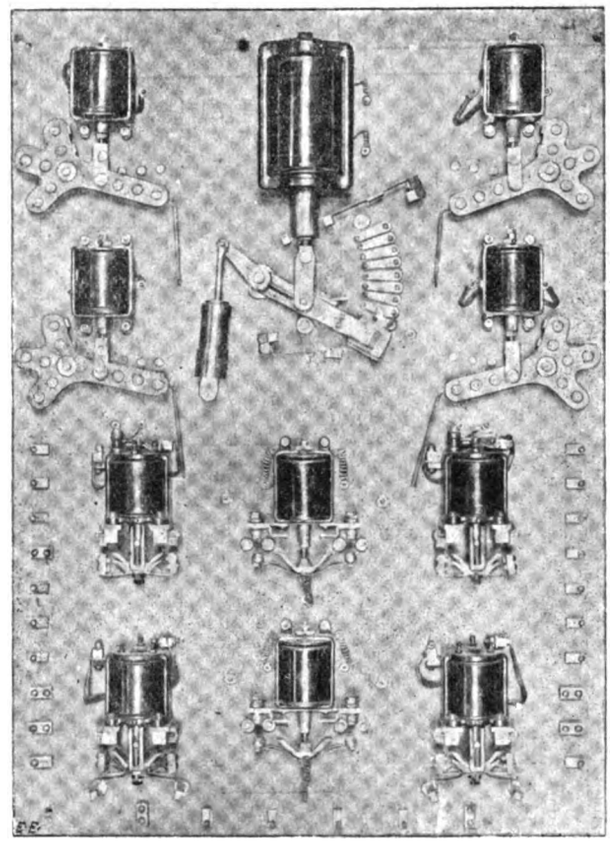

FIG. 16.

the car is pushed. The first effect is to energise the reversing switch in the right direction; then the main solenoid is energised and the motor is started, while the supplementary solenoid connected with the button pushed will cause the motor to stop at the desired floor.

A simpler form of the same type of switch is used when it is desired to operate a crane from various floors. Take the case where a jib crane is used to convey goods to the various floors of a five-storey building. It is then desirable that the crane shall be operated from any floor, while at the same time it shall be impossible for any person at another floor to interfere with the process of raising or lowering that may be carried on at the time from a different floor. A diagrammatic illustration of the arrangement is given in Fig. 17. Here we have two solenoids, A and B, through the centres of which pass an iron core, on which is mounted a lever which operates a reversing switch. Either of the two solenoids can be energised from any number of points, and the same current can also energise the ordinary form of solenoid switch. If we take the case when the operator on any floor wishes to raise the hoisting tackle, he closes the switch which controls solenoid A, and the iron core is drawn towards this solenoid, and the reversing

Digitized by Google

switch is then thrown over into the proper position to give the correct direction of rotation. If, now, some other person wishes to operate the motor in the other direction, he cannot do so until the first person opens his switch, because when the iron core has been pulled towards A this solenoid will more strongly attract the iron core than will the solenoid B, and hence the motor will not rotate in the reverse direction until the solenoid A is de-energised. The switch directly operated by the lever attached to the iron core can either be the main reversing switch, or it can operate this through a solenoid auxiliary switch.

As a general rule, for all private installations, whether supplied with current from the public supply mains or from an isolated generating plant, it is better to insert a separate speed-regulating switch apart from the starting switch whenever speed variation is required; but in the case of printing presses, tramcars, and other special cases this

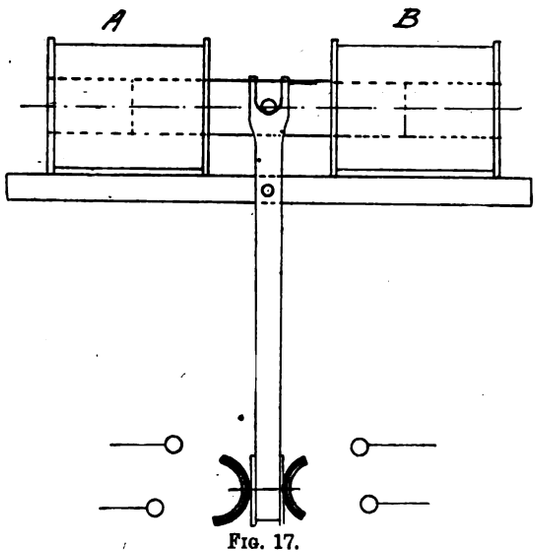

FIG. 17.

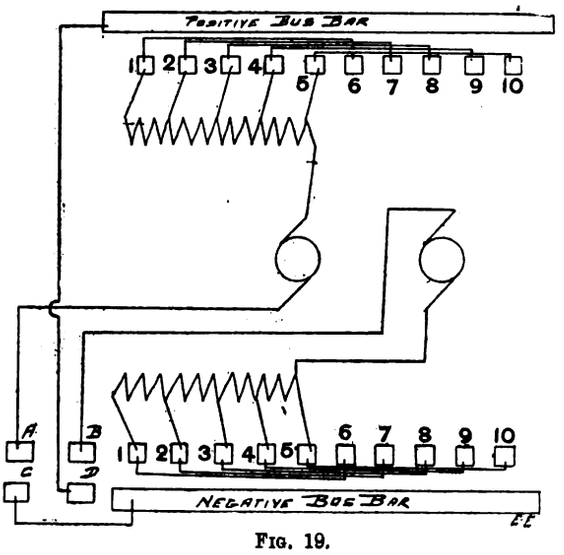

FIG. 19.

course cannot be adopted owing to the special nature of the requirements, and in these cases a more complicated type of starting switch, or what is more correctly termed a controller, is necessitated by the special needs of the apparatus.

Fig. 18 gives an illustration of the general form of the tramway controller as made by Messrs. Royce, Limited. In tramway work, as a general rule, two motors at least are placed on each car, and these must be connected up in series or parallel at will in order to obtain the necessary variation of speed. At the same time, it is important that the operation of starting always follows a proper course, so that it be impossible to suddenly throw the machines in parallel when they are running in series and *vice versâ*. The method adopted to obtain the requisite results are shown diagrammatically in Fig. 19. It will be noted from this diagram that the speed variation is obtained partly by means of rheostatic control in the armature circuits and partly by means of series and parallel running of the two motors. When the machine starts from rest the two armatures must be in series, with all the resistance in circuit; this resistance must then be gradually cut out, until the armatures are directly connected across the mains in series. Afterwards they must be thrown into parallel with all the resistance reinserted; and, again, this resistance must be gradually cut out in order to obtain the top speed, until finally the two machines are running in parallel with the armatures directly connected across the supply.

To obtain this result the controller is made having the equivalent of two (positive and negative) 'bus bars with an equal number of contacts to each, so arranged that when the positive contact 1 is joined to the positive 'bus bar the corresponding negative contact 1 is also joined to the negative 'bus bar, and so on. In addition to this there are four additional contacts, marked A B C D, required for coupling up the armatures in series or parallel. The first motion of the starting switch or controller energises the fields of the motors and closes the connection between A and B, and thus connects the two armatures in series. The next motion closes the armature circuit through all the external resistance, the next motion cuts out a

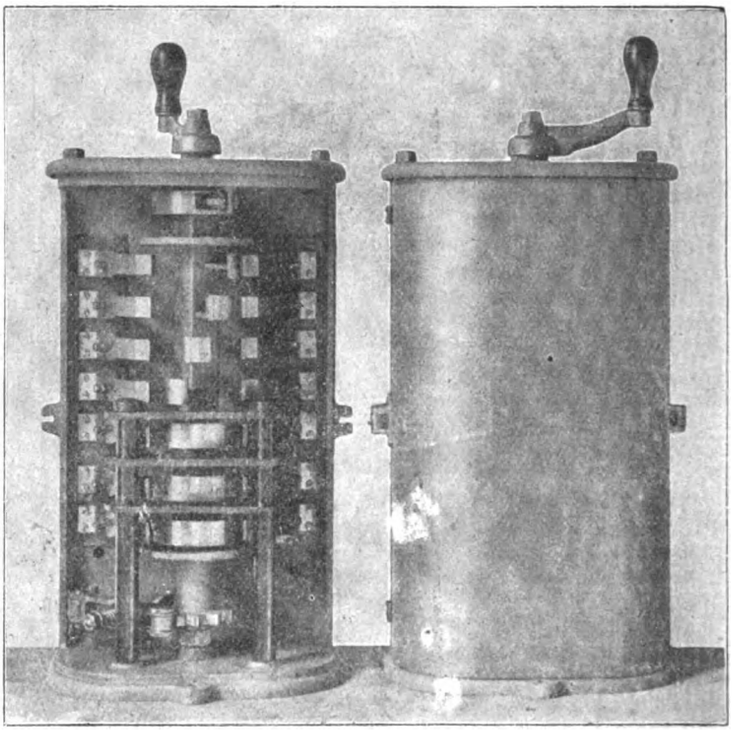

FIG. 18.

certain portion of the resistance, and this is continued until contact 5 is reached, when the armatures are directly connected in series across the points of supply. Upon moving the controller so that the movable contact pieces join contacts 6 6 to the 'bus bars simultaneously, the circuit is opened between A and B and closed between A and C and B and D, thus joining the armatures in parallel across the mains; then as the motion of the controller is continued, the resistance which was inserted when contacts 6 6 were reached is gradually cut out. The operation is simple, but the controllers must be well made and every care must be taken to obtain a quick break, so as to minimise the risk of arcing; this is a most important point, as it must be remembered that the motors will operate at probably 500 volts.

In the teazer systems of control the same general principles have to be adopted. Here the actual operation is somewhat different. There are two generally-accepted systems of motor-teazer control—viz., the Bullock and the Holmes-Clatworthy. In the first the auxiliary machine consists of a small motor-generator, and the first operation consists in starting the motor of the teazer portion of the equipment through an external armature resistance; the motor commences to rotate slowly, and the current given

Digitized by Google

out by the generator is supplied to the main motor; the speed of the teazer motor is gradually increased by the controller cutting out the armature resistance, and consequently the E.M.F. generated by the dynamo is raised, and the main motor rotates at a higher speed. As this speed is increased, the circuit between the main motor and the supply is closed through an armature resistance, and this main motor is then taking current partly from the mains and partly from the generator of the teazer equipment. Finally, the circuit through the teazer is opened, and the main motor takes current only from the mains, at first through an armature resistance, and at last direct. If a higher speed be required, this is obtained by inserting a resistance in the field circuit.

In the Holmes-Clatworthy system the device adopted is slightly different, as there is no alteration in the value of the E.M.F. Here the auxiliary motor drives the main motor through gearing when the equipment is first started. Gradually the speed of the auxiliary motor, and consequently that of the main motor, is increased by cutting out the resistance in circuit with the teazer armature. The circuit is then closed between the main motor armature and the supply through a resistance, and as this resistance is cut out the speed increases, until finally the teazer motor automatically drops out of gear and is stopped. Final adjustments of speed are made in the same manner as is the case with the Bullock equipment.

It will be noted that the general arrangement of the controller in either case is very similar to that of the tramway controller already described. There is thus no necessity to describe the construction or function of them in any detail. The object of referring to them was to emphasise the remarks made in the first article on the necessity for sound and well designed starting switches for operating every size and type of motor. It is a matter of the rarest occurrence for one of these controllers, whether for tramway use or for use in connection with a teazer equipment, to break down or to give any trouble, and yet it is apparent that they are far more complicated than any type of starting switch used in ordinary practice with isolated motors. The reason is not far to seek. The manufacturers of the teazer sets and of the tramway motors are fully aware of the trying conditions under which their equipments have to work, and will only supply these motors on the understanding that proper controlling apparatus is installed with them. It is necessary to see that not only the controllers but also the whole plant is kept clean. The necessity of this is impressed on the users, who soon learn that the plant is so delicate that if it does not receive proper attention it will refuse to work, and therefore this class of equipment does receive proper attention, but not more than any piece of machinery should receive. Let the contractor for a motor installation and the purchaser of the same compare these results with the reports of the various insurance companies who insure and inspect electrical machinery. They will see from these reports that at least one machine in nine breaks down annually, and in 90 per cent. of the cases the cause is put down to dirt or to faulty, poor, and defective starting apparatus. Then if they consider that nearly every morning newspaper is printed by electrically-operated presses, and that even the large London dailies do not keep any stand-by plant either in the form of spare motors or controllers, and that such a case as the failure to publish through the breakdown of the electrical equipment is unknown, they should be forced to the rational conclusion that it is one of the greatest mistakes to reduce the cost of an installation by adopting a cheap and inefficient form of starter, and so to court certain breakdown of the plant and dislocation of work in the near future, but that, on the other hand, the money is well expended that is spent in installing the best—not necessarily the most costly—starting switches, which should be designed for the particular class of work the motors are called upon to do.

Erratum.—We regret that when dealing with "Electric Lighting for the Inexperienced," which we reviewed in our issue of the 11th ult., the author's name was given as "Herbert Walton," instead of Hubert Walter.

THE USE OF IRON IN ALTERNATE-CURRENT INSTRUMENTS.*

BY W. E. SUMPNER, D.SC., MEMBER.

(Continued from page 809.)

I now pass to the consideration of wattmeters. The introduction of electromagnets into these instruments is naturally a more difficult problem. With the exception of electrostatic instruments, all accurate wattmeters are of the dynamometer type. Iron, and, indeed, all metal parts, are severely excluded, with the result that these instruments are insensitive, lacking in range, and subject to disturbances caused by external fields. It has, nevertheless, become necessary to use transformers in conjunction with them, owing to the high potentials and heavy currents now common. These accessories, of course, contain iron, and introduce errors, due to small differences in phase, which are as serious, I believe, as those which would arise from the use of well-designed electromagnets in the wattmeter itself.

The error in wattmeters due to the lag of current in the pressure coil has frequently been theorised about, but I think a somewhat exaggerated idea exists as to its nature and extent. A commercial wattmeter is intended to work on circuits of fixed voltage and for a maximum load current. I have calculated in the accompanying table the wattmeter error caused by 1deg. lag in the pressure coil for a fixed load current corresponding, say, with 1,000 volt-amperes and for loads of different power factor.

TABLE I.—Wattmeter Error for a Load of 1,000 Volt-Amperes (for a Lag of 1deg. in the Pressure Coil).

Power factor.	True watts.	Error.	Error per cent.
1·0	1,000	·3	·03
·9	900	7·6	·85
·8	800	10·5	1·31
·7	700	12·5	1·78
·6	600	13·9	2·32
·5	500	15·1	3·02
·4	400	15·9	3·98
·3	300	16·6	5·54
·2	200	17·1	8·55
·1	100	17 3	17 3
·02	20	17·4	87·2

The error increases the reading if the load current lags, and diminishes it if it leads. If the power factor of the load is cos ϕ, the error in the reading is proportional to sin ϕ, while tan ϕ represents the error per cent. of the true reading. It will be seen that the error in the reading, instead of indefinitely increasing as the power factor diminishes, rapidly attains a maximum value, which is less than 2 per cent. of the reading corresponding with the same current if non-inductive. The error per cent. may be enormous for low power factors, but the error as a deflection may all the same be unreadable unless the instrument has a wide scale. (The theory of this error, and the application to wattmeters used on three-phase circuits, are given in the appendix.)

The lag in the pressure coil can be easily reduced to one-tenth of a degree, and the error caused by it is proportionately diminished. It is not so well known that the phase differences introduced by current and voltage transformers can, if these are properly designed, be reduced to similar small values. Of course, the errors due to such phase differences are of the same nature and importance as if they were all due to lag in the pressure coil.

Electromagnets may be introduced into wattmeters either by putting the magnetising coil in series with the current or by connecting it in shunt across the mains. In the former case, owing to hysteresis, eddy currents, and varying permeability, the induced magnetism will not properly follow the variations of the current, even when the magnetic circuit contains an air-gap and only low magnetic densities are needed. On the other hand, if a shunt coil is used to produce the magnetism, not only is there an error due to the resistance of the coil, but the flux of magnetism is practically in quadrature with the voltage producing it. The resulting errors can, perhaps, be made negligible in either case, but it is the latter method I have tried

* Inaugural address of the Chairman, delivered before the Birmingham Local Section of the Institution of Electrical Engineers.

Digitized by Google

experimentally lately, in order to bring the question before you.

If N is the magnetic flux in the core of a transformer or electromagnet produced by a current, C, through a winding of n_1 turns of resistance, R, the voltage, V_1, necessary to produce this current is given by

$$V_1 = R\,C + n_1 \frac{d\,N}{dt}.$$

We also have $$V_2 = n_2 \frac{d\,N}{dt},$$

where V_2 is the voltage on open circuit of a secondary winding of n_2 turns (assuming no magnetic leakage). For large transformers on open circuit the term R C may be less than one-ten-thousandth part of V_1. For magnetic circuits of small dimensions, suitable for instruments, especially if an air-gap is introduced to allow a moving coil to cut the flux, the term R C is much larger compared with V_1, but may still be a small proportion of it. As a rule the copper drop, C R, is by no means negligible compared with V_1. This is only too noticeable when testing small masses of iron for hysteresis losses by the wattmeter method, since the losses in the magnetising coil are often an appreciable fraction of the whole. In such cases I have often found it convenient to use two windings (as shown in Fig. 5), one of a few turns, n_1, suitable for a considerable magnetising current, C, passed through the current coil of the wattmeter, W; the other of a large number of turns, n_2, connected with the pressure coil of the instrument. The reading of the wattmeter must then be divided by the ratio n_2/n_1 in order to get the watts wasted in the iron circuit. This method has several advantages. Only the core losses are measured,

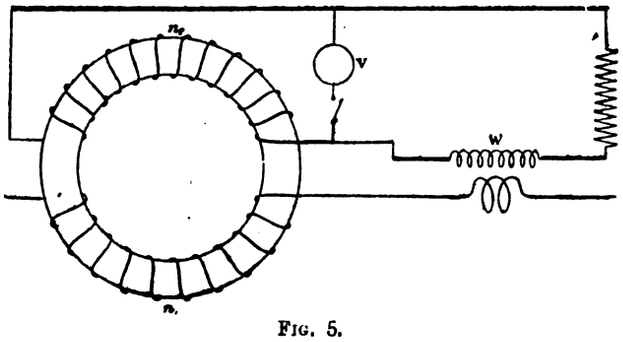

FIG. 5.

the losses in the magnetising coil becoming a matter of indifference. A wattmeter suitable for heavy currents, and the measurement of large amounts of power, may be utilised for the estimation of only a few watts; and the flux can be calculated independent of the copper drop in the primary coil, by attaching a voltmeter, V, to the secondary coil, the resistance of this being allowed for, if need be, by the ordinary fall of potential method.

Unfortunately, there does not appear to be any similar method of eliminating the copper drop when the electromagnet is to be used as part of the wattmeter itself. The effect of hysteresis, eddy currents, and variable permeability is to alter the R C term; but if we assume that by suitable design this term R C can be made negligible compared with V_1, we have

$$V_1 = n_1 \frac{d\,N}{dt},$$

and hence, whatever the nature of the iron, the strength of the flux, N, and, therefore, the magnetic density in each part of the air-gap is strictly proportional to V_1, and in perfect quadrature with it. If now the load current, A, be passed through the primary of an air-core transformer (shielded, if necessary, from external fields by a shell of suitably laminated iron), the voltage induced in the secondary coil will be proportional to A in magnitude, and in quadrature with it as regards phase. It may thus be used to produce a minute current, a, through a large non-inductive resistance, and the moving coil of the instrument. Theory then shows (see appendix) that if a is in quadrature with A, and if N is in quadrature with V_1, the torque on the moving coil is proportional to the average value of the product $V_1 A$, and, therefore, measures watts, independently of frequency and wave-form, and of the nature of the iron used in the electromagnet.

The first instrument using this principle which I had made was of the reflecting type, having a metallically suspended coil as in ordinary moving-coil galvanometers. Its action was promising. I have since constructed two

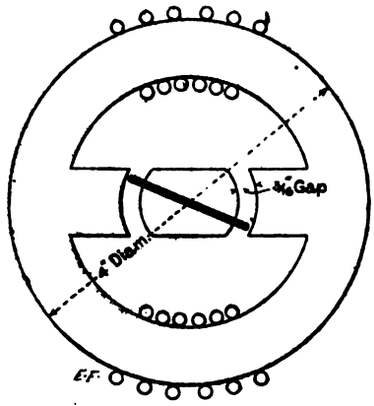

FIG. 6.

non-reflecting instruments (illustrated in Figs. 6, 7, and 8) which I now show you. In each of these instruments the moving coil is exactly similar to those used in commercial moving-coil instruments for direct currents. They are pivoted and controlled by helical springs of the usual kind The magnetic circuits are indicated in Figs. 6 and 7. That of the earlier instrument is of the Manchester dynamo type and contained two air-gaps. The later instrument has a magnet of the Lahmeyer type, but arranged to have only one air-gap, the moving coil turning about an axis coincident with one of the long sides of the coil, and placed outside the magnetic field, the opposite side moving through the air-gap. The magnetic circuit is jointed along the line J J to allow the insertion of the coils. The complete instrument with its current transformer and resistance is shown

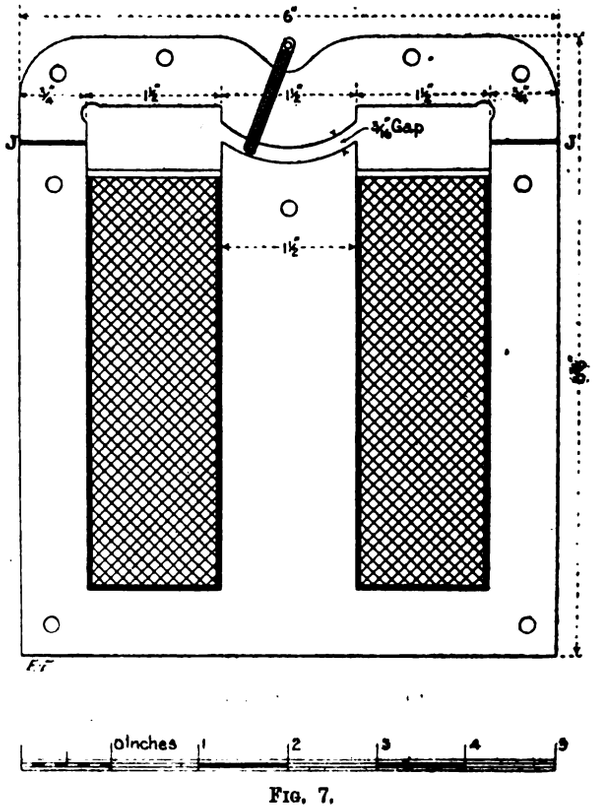

FIG. 7.

in Fig. 8. By winding the magnetising coil on the centre limb as in Fig. 7, instead of on the two side limbs as in Fig. 6, the effect of an ampere-turn is doubled, and by reducing the number of air-gaps from two to one the effect is again doubled. To further reduce the copper drop, C R, as compared with V_1, the voltage on the magnetising coil,

Digitized by Google

this coil should be liberally supplied with copper, and should fill as much winding space as possible. Of course, the air-gap should be a minimum. In the instruments shown each air-gap is $\frac{3}{16}$in. across. It is quite possible to halve this and still allow plenty of room for the free movement of the coil.

The calibration curve of the instrument outlined in Fig. 6 was tested by passing direct currents through the fixed and moving coils. For magnetising currents producing air-gap densities similar to those found in direct-current moving-coil instruments, the calibration curve obtained by varying the current in the moving coil was always of the same shape. When the deflection was interpreted by means of this calibration curve, the reading was found strictly proportional to the product of the currents in the two coils. The instrument was then tested with alternate currents against a standard wattmeter on a non-inductive load of lamps. A voltage transformer was used to reduce the voltage of the circuit to one suitable for the instrument. The minute current through the moving coil (having 50 turns and a resistance of six ohms) used in series with a non-inductive resistance of 300 ohms, was taken from a few turns of thin wire forming the secondary of a small iron-cored transformer, the primary of which consisted of two turns carrying the load current. The experiments

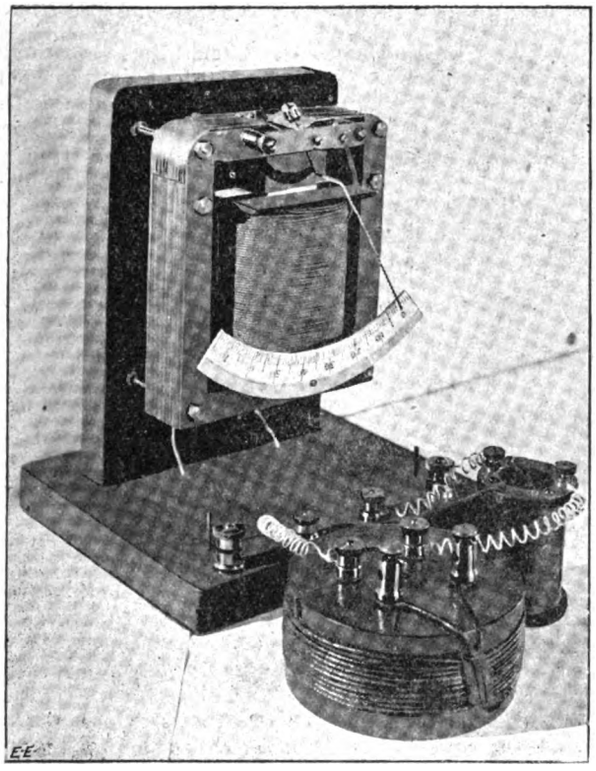

FIG. 8.—Wattmeter, with Current Transformer

showed that the calibration curve, or the relation between deflection in degrees and watts, was exactly the same as that obtained with direct currents, the load being non-inductive throughout the tests. When the power factor of the load was suddenly altered from 1·0 to about 0·1, it was, however, found that the constant of the instrument was considerably changed. This result was due partly to the fact that the copper drop in the magnetising coil was not negligible compared with the applied voltage, but it was also largely due to the phase differences introduced by the two transformers, each of which had closed iron magnetic circuits. These transformers were, indeed, quite unsuited for the purpose, and the copper drop in the magnetising coil of the instrument was (at 40 cycles) about 20 per cent. of the total voltage applied. But even under these circumstances the deflection of the moving coil, as interpreted by the calibration curve obtained with direct currents, was strictly proportional to the watts for a load constant in power factor and frequency.

No further experiments were made on this instrument, which was constructed simply out of such stampings as were to hand, while waiting the arrival of special stampings ordered for the instrument shown in Fig. 8. In this instrument much more space was allowed for the magnetising coil, and in other ways already mentioned the construction was modified with the view of reducing the copper drop. The magnetising coil consists of 1,051 turns of No. 18 wire, having a resistance of 3·68 ohms. The section of the middle limb of the magnetic circuit is a trifle over two square inches, the length of the winding bobbin is about 4in., the air-gap is $\frac{3}{16}$in. The moving coil consists of about 60 turns, having a resistance of 5·4 ohms. The structure is such that the moving coil can turn through an angle of 80deg. without leaving the field. Testing with currents of 80 cycles per second, it was found that 54 volts produced a current of 0·13 ampere through the magnetising coil. It follows that the copper drop is only 0·88 per cent. of the applied voltage, when the frequency of the current is 80. This means that, even supposing there are no hysteresis or other

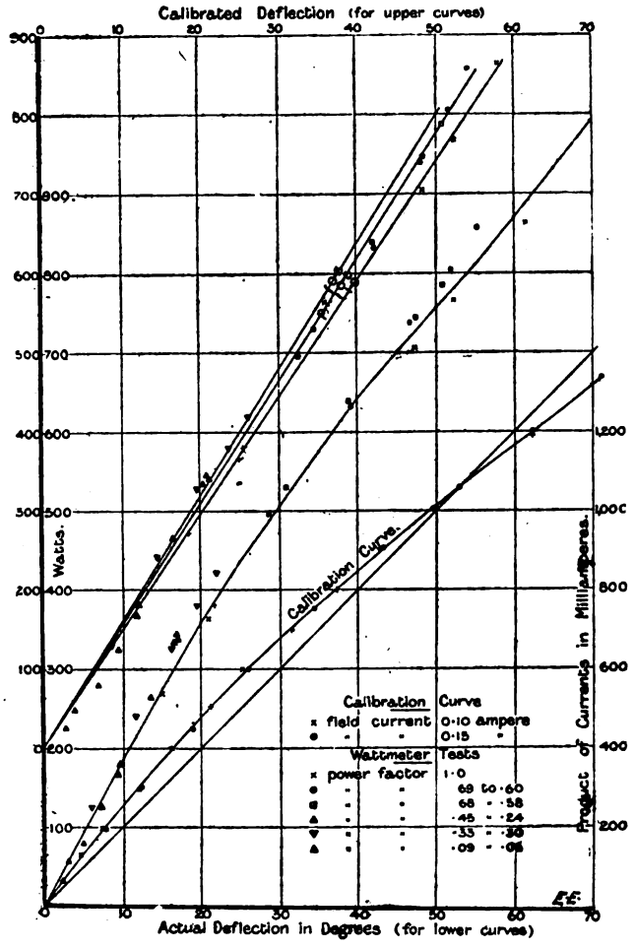

FIG. 9.

losses in the iron circuit, the phase of the applied voltage cannot differ from that of the induced voltage due to the flux in the coil by more than ½deg. If there are hysteresis losses, this phase difference will not be increased, but diminished, since the vectors representing the copper drop and the voltage due to the magnetic flux will no longer be at right angles to each other. In fact, hysteresis is an advantage from this point of view, although, of course, it increases the losses involved in producing the electromagnet. The losses in the magnetising coil are quite trifling. The copper losses for 0·13 ampere only amount to 0·062 watt. The iron losses I have not measured, but they must be small owing to low induction density and the small volume of iron. For the current transformer for this instrument I have simply wound a coil of 10 turns (resistance 0·0163 ohm) so as to surround a secondary coil of about 600 turns having a resistance of 8·5 ohms. No iron was used with this transformer. The copper losses for 20 amperes through the primary are 6·4 watts. These could easily be made negligible by using thicker wire.

The results of several tests on the instrument with a resistance of 500 ohms in series with the moving coil and

Digitized by Google

the current transformer are shown in Fig. 9. The calibration curve was first found by taking two sets of tests with direct currents. In one of these the magnetising current used was kept constant at 0·10 ampere, and in the other set it was made 0·15 ampere. Various currents were passed through the moving coil, and the corresponding deflection in degrees shown by the pointer was noted. When the product of the two currents, each measured in milliamperes, was 1,006, a deflection of 50deg. was obtained. The observations are plotted to form the calibration curve, the two sets of points being distinguished by different signs, as shown. It will be noticed that both sets of points lie well on the same curve. A straight line is drawn from the zero through the point corresponding with 50deg., in order to show the deviation of the calibration curve from strict proportionality. Six sets of tests with alternating currents were then made on loads of different power factor, but with the current frequency kept constant at about 80 cycles, and the voltage of the circuit in all cases being about 60. In each set of tests, except for the non-inductive load, the power factor of the load diminished as the current and deflection increased, the limiting values being indicated, and the points corresponding with different sets of tests being separately distinguished (as shown in Fig. 9). The line drawn among the points is a reproduction of the calibration curve, the ordinates of the latter being all increased by 50 per cent., in order to show how far this curve indicates the relation between the deflection and the watts. It appears from these tests, and from numerous others which I have made, that the same calibration curve holds for the instrument under all circumstances, or, in other words, that for a specially prepared scale determined from this calibration curve the reading of the pointer will be proportional to watts for a varying load of any fixed power factor and frequency. The constant to be used with such a scale is the same for all currents and voltages if the power factor and frequency are unaltered, assuming, of course, no change in the transformer circuit. The constant of the instrument does change to some extent for alterations of frequency and power factor. For the tests shown in Fig. 9 the frequency was kept at 80 cycles, but the power factor of the loads used in the experiments ranged between 1·0 and 0·06. The divergencies of the plotted observations from the calibration curve drawn among the points indicate the alteration of constant with the power factor of the load. To show this more clearly the observations have been replotted as shown in the upper curves of Fig. 9. In these curves the observed power in watts is plotted, not with the actual deflection of the instrument, but with the calibrated deflection as determined from the calibration curve for a scale properly graduated, and such that the reading is 50 for a deflection of 50deg. Under these circumstances all the observations for loads of the same power factor should lie on a straight line drawn through the zero, and this proves to be the case. It appears from these tests that the constant for unity power factor loads differs by about 4 per cent. from that for loads of power factor 0·6, and by about 8 per cent. from that for loads of 0·3 power factor. These changes are much greater than correspond with the phase difference of about 0·5deg. due to the copper drop in the magnetising coil, since reference to Table I. will show that for the power factors mentioned the changes in the constant should be respectively only 1·16 per cent. and 2·27 per cent. This shows that the main part of the alteration of constant is caused by the current transformer, which was not specially designed for the purpose, and the errors caused by which I have not yet had time to investigate. This view is confirmed by tests showing the effect of alteration of frequency. With the same resistance, of 500 ohms, in series with the transformer secondary circuit, as used in the tests shown in Fig. 9, I found that for non-inductive loads traversed by currents the frequency of which varied from 93 cycles to 43 cycles, the alteration of the constant was 1·4 per cent. This change is very much greater than corresponds with the phase difference of half a degree at 80 cycles caused by the copper drop. The error due to the transformer can be reduced by diminishing the number of secondary turns, by increasing the number of primary turns, or by increasing the secondary resistance. Similar tests made, with a resistance of 750 ohms in the transformer circuit, showed a change of constant of less than 1·0 per cent. for frequencies varying between 100 cycles and 45 cycles. A set of tests on the effect of power factor made with this resistance in series with the moving coil, and at a frequency of 80 cycles, showed no measurable alteration of constant for power factors ranging between 1·0 and 0·1. Of course, there must have been some error, but in such tests as I have as yet had time to make I was unable to detect it, and there seems no doubt that the error is much less than in the previous tests.

Now, in my opinion, no wattmeter should be considered a satisfactory instrument if it has errors like some of those mentioned. Though it will hardly be denied that many commercial instruments present greater errors in practice, I am not concerned to-night with any claim that the instrument shown you is accurate under all conditions. Still less am I concerned to show that the use of transformers with wattmeters must necessarily introduce grave errors. On the contrary, my belief is that however faulty some wattmeters may be when used with transformers, a little attention given to the design of the latter will reduce the resulting errors to a negligible amount. This will, I believe, also prove true for transformers of the particular type needed for the instrument I have described. The chief importance attaching to the tests referred to is due to the light they throw upon the question of the possibility of constructing good wattmeters with iron-cored electromagnets.

The greatest errors arising in practice in wattmeter readings are neither due to transformers nor to intrinsic faults in the instruments. They arise from the presence of heavy currents in neighbouring conductors. Some wattmeters are protected from such influences by surrounding the coils with a shield of suitably laminated iron. Iron is used for the transformers, and is used for these surrounding shields. Iron is used anywhere and everywhere, except in the place where it is most efficient—namely, within the coils of the wattmeter itself. In the instrument I have shown you iron has been put in the wattmeter, and has been removed from the transformer coils. The shield may still be needed to protect these coils, but not for the instrument itself, since this will be even less affected by external fields than ordinary permanent-magnet voltmeters and ammeters.

I foresee no difficulty in rendering negligible the error due to the transformer, and the instrument itself can be much improved upon. The length of the air-gap can be reduced, and other arrangements made to further diminish the copper drop as compared with the voltage applied to the magnetising coil. There is a discrepancy between the flux density in the air-gap as calculated (1) from the number of turns, the applied voltage, the frequency, and the section of the circuit; and (2) from the number of ampere-turns on the coil, the length of the air-gap, and the other particulars of the magnetic circuit. This is possibly caused by undue eddy currents, which reduce the effectiveness of the ampere-turns and increase the copper drop. If so, the use of thinner stampings will improve matters. But as the instrument stands, it is as good a wattmeter as many using current and voltage transformers, while it possesses greater range and is more sensitive. My main object is to show that the errors arising from using iron magnetic circuits in wattmeters are not necessarily greater than those involved in the use of transformers with such instruments. I consider that the action of the instrument shown justifies this view.

If it be once granted that the errors can be rendered sufficiently small, no one will doubt the great advantage of an iron-cored instrument, or dispute its supremacy in regard to sensitive qualities. It must necessarily be as delicate as a permanent-magnet, moving-coil instrument, since the magnetic field can easily be made as strong, or even stronger. An instrument such as illustrated in Figs. 7 and 8 can be utilised for the detection of very small alternating currents or voltages. Of course, phase difficulties arise, but these can be overcome by making use of phase-changing devices for applying a voltage of the right phase to the magnetising coil.

The influence of small differences of phase on the action of alternate-current instruments can generally be calculated

Digitized by Google

if the phase differences are known, but these are difficult to determine experimentally. In order to investigate the action of transformers for instrument purposes, I have devised voltmeter methods for measuring small phase differences. It would take too long to explain these now, but I have set forth in Table II. the results of a number of recent measurements. In carrying out these tests I have had the benefit of the able assistance of my colleague, Mr. David Owen. The phase differences measured are given in the column headed θ.

TABLE II.

The last column shows for the smaller values of θ the number of parts in *one million* by which cos θ differs from unity. The first number given relates to a common water resistance, and implies that its power factor may be taken as 0·999978. This should bring comfort to anyone who has doubted the non-inductiveness of such resistances. The values of θ given for the wire spiral and for the direct-current arc are the minimum values I could detect with certainty with the voltmeters I had at disposal when the tests were made; consequently all that these numbers prove is that the power factor in these cases does not differ from unity by more than corresponds with the figures given. Then follow a number of tests on voltage transformers of various capacities, with the secondaries, in some cases on open circuit, and in others supplying currents of various magnitudes and power factors. The last three tests were on current transformers with secondaries closed on the circuits for which they were designed. It will be noticed how exceedingly small the value of θ is for some of the transformers on open circuit. This is of special interest in regard to electromagnets for wattmeters, since such electromagnets are essentially transformers on open circuit, and the phase difference measured is that caused by the copper drop in the magnetising coil. For the one-unit equal-ratio transformer this value of θ is only 0·02deg., and cos θ differs from unity by less than seven parts in *one hundred million*. On full load θ is only $\frac{1}{3}$deg., and is much the same for a load of power factor 0·09 as for unity power factor. The three-unit transformer shows a lower phase difference for inductive loads than for non-inductive, and it is noteworthy that a very sharply-defined minimum value of θ of 0·18deg. occurs at about 80 per cent. of the full-load current, with a secondary circuit of power factor 0·09. The small 10-ampere transformer was supplied by the British-Thomson Houston Company to reduce current in the ratio of 20 to 1, for any secondary resistance not absorbing more than two volts or 0·5 ampere. The phase difference between the primary and secondary currents at full load is less than $\frac{1}{10}$deg. The five-ampere current transformer was supplied by a firm of the highest standing for use with one of their own wattmeters. The large phase difference found of 2·3deg. would seem to imply great error in use, yet on fully considering all the conditions of the instrument, I find that the error in reading works out to be only 1·7mm. on the scale, even when the full currents—*i.e.*, such as to produce full deflection on a non-inductive circuit—are flowing in the coils, and the power factor of the load tested is the lowest for which the instrument is guaranteed—viz, 0·6. For smaller load currents this error is proportionately diminished, and it disappears altogether on high power-factor circuits.

My object in bringing these numbers before you is to afford evidence for my belief that while transformers as supplied commercially for wattmeters may in many cases be such as to cause phase differences of more than one or two degrees, it nevertheless seems true that a little care spent in designing them would result in reducing these angles in practice to about $\frac{1}{10}$deg. Even as matters stand, the errors caused by them are less than is generally supposed. They are, however, greater than those which need result from the introduction of iron-cored electromagnets into wattmeters and other alternating-current instruments. Under these circumstances my contention is that such instruments should be designed on the lines of the permanent-magnet moving-coil instrument, and that well-considered efforts in this direction will command success.

The object in view is no small one when we consider how much electrical advance, which has all been based on exact measurement, really owes to the introduction of sensitive galvanometers and voltmeters for direct currents; and that, in all probability, similar instruments for alternating currents will lead to important developments also. At all events, when we think of electrical progress in the past, it is only fitting for us to remember how greatly this has been dependent upon the work of one man. When most of us commenced to study electricity, the name of Sir William Thomson was already historic. When *he* first started the subject, the instruments available for testing were of a kind such as are only now used for class teaching of the most elementary description. But at a time before most men now living were born, and at an age younger than most of us now present, Sir W. Thomson applied for the first time to the structure of instruments skilful engineering design. He altogether revolutionised them, and brought them to such a state of perfection that, except in comparatively small details, they have not been improved upon since. The Thomson reflecting galvanometer, the siphon recorder, and the quadrant electrometer represent the best instruments of to-day, as they did when first introduced as long ago as the middle of the last century. The sudden increase of sensitiveness then secured constituted a step in advance quite unexampled either before or since. It is as difficult now to properly realise its magnitude as to truly estimate its influence on electrical development. But we are all glad that Lord Kelvin has been able not only to take a great leading part in, but also to watch, the *whole* of this progress, and that we can still congratulate him on possessing the enthusiasm and mental activity of younger men.

(To be continued.)

Action of Radium Emanations on Diamonds.—The *Proceedings* of the Royal Society contain Sir William Crookes's contribution on this subject. An "off colour" diamond, of a very pale-yellow colour, was put inside a tube with radium bromide, and after 78 days the diamond had darkened and become bluish-green in tint, no yellow colour being apparent. When heated at 50deg. in a mixture of nitric acid and potassium chlorate for 10 days, the diamond lost its dull surface colour and was bright and transparent, but its tint had changed to a pale bluish-green. The radium emanations have accordingly a double action on the diamond. The β-rays effect a superficial darkening, converting the surface into graphite in a manner similar to, but less strongly than, the more intense electrons in the cathode stream. In the presence of radium, the diamond is extremely phosphorescent, and continues to shine during the time of the experiment. The diamond which had been submitted to the action of radium was still strongly radio-active after it had been away from radium for 35 days, for 10 of which it was being heated in a mixture powerful enough to dissolve its outer skin of graphite.

TRADE NOTICES AND NOVELTIES.

Improved Ball Bearings for Electric Motors.

In order to improve the efficiency of electric motors, the Lahmeyer Electrical Company, Limited, have recently given special attention to the design of the bearings, and are now introducing small motors fitted with ball bearings of an improved type, whereby the losses due to friction are reduced to a minimum, great saving is effected in the consumption of oil, and the space occupied is less than for motors fitted with

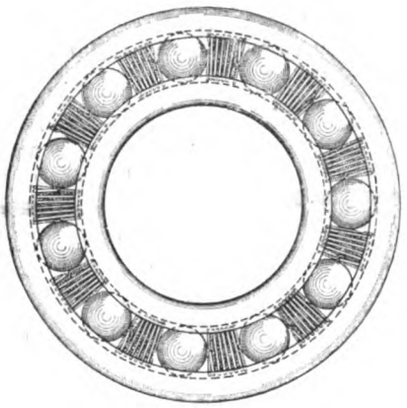

FIG. 1.

ring lubricated bearings. Instead of filling the whole space between the inner and outer rings with balls, as hitherto, a smaller number is provided, the spaces between the balls being fitted with springs, as shown in the accompanying illustration (Fig. 1). If, in consequence of the bend of the shaft there is a tendency of the outer ring to get out of truth with the inner ring, the variation in the speed of the balls, due to their running on a periphery of smaller radius at the upper and lower parts of the bearings than in the lateral parts, is counterbalanced by the

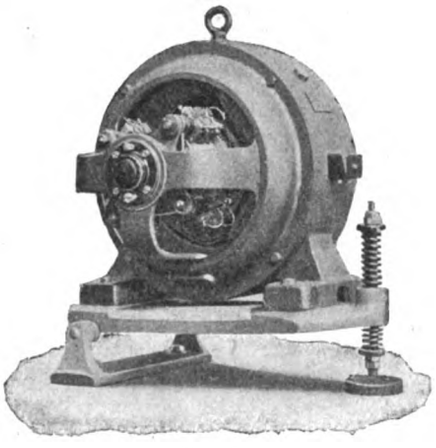

FIG. 2.

action of the springs, so that the balls will not be damaged. A further advantage of this design is that the springs are filled with felt, which forms a rotating lubricating machine. Easy access to the balls for the purposes of inspection, etc., is provided for. Fig. 2 shows a Lahmeyer continuous-current machine fitted with ball bearings. Single-phase alternating-current, two-phase, and three-phase small motors similarly fitted are also being constructed by the firm.

Enclosed Arc Lamps.

From the Union Electric Company, Limited, 151, Queen Victoria-street, E.C., we have an advance copy of their new list of "E. V." and "E. V. S." type enclosed arc lamps for direct-current circuits. The "E. V." lamps are made both single and double enclosed, and of two burning periods—viz., 100 hours and 300 hours. In each case the remains of the positive carbons are used up when trimming as the negative carbons, thus effecting a very great saving in the cost of the carbons. With the 300-hour type a special arrangement has been introduced, securing a minimum consumption of carbons and ensuring practically no deposit on the inner globes. The "E. V. S.," or traction type, lamp, is specially constructed for burning in long series, and for remaining unaffected by instantaneous and large changes in voltage.

Comstick.

Mr. S. W. Cuttriss, M.I.E.E., Prudential-buildings, Park-row, Leeds, has sent us a sample of a preparation known as Comstick, which he has been manufacturing some years for the specific purpose of lubricating the commutators of dynamos and motors having metal brushes. It is claimed that Comstick will keep the commutator in good condition, prevent cutting, and promote that high gloss which is so desirable. Graphite apparently enters largely into its composition. The valuable properties of this material as a lubricant are well known. There is no doubt that the judicious use of a preparation such as Mr. Cuttriss supplies in the handy form of a stick will greatly help to maintain a commutator in good condition. Too much pressure of the brushes on the commutator, coupled with the absence of suitable lubrication, is responsible for much of the turning up which has to be done. We should have been glad to have tested the merits of Comstick ourselves, but the machines at our disposal for the purpose do not happen to be fitted with metal brushes.

Model Dynamos, Motors, etc.

"Electrical Novelties" is the title of a catalogue recently issued by Messrs. F. Darton and Co., Clerkenwell Optical Works, London, E.C. The contents of the catalogue comprise a large number of model dynamos, motors, and gas-engines, besides accumulators, medical coils, and sundry apparatus, in which we understand the firm are doing a large and increasing business.

Calendars and Catalogues.

CALENDARS.—Wm. Augs Gibson, Limited, makers of hydraulic and electric lifts, 28, Fleet-street, E.C. An ornament to any office.

CATALOGUE.—Heathman and Co., Parson's Green, Fulham, S.W., patent extension ladders, folding steel ladders, wheeled ladders, telescopic trestles, etc.

PERSONAL.

The Bridlington Corporation have appointed Mr. Arthur J. Beckett as resident engineer at the new electricity works, at a salary of £210, rising by £10 per annum to £250. Mr. Beckett has been acting as clerk of the works during the installation.

The Glasgow Corporation Tramway Sub-Committee have agreed to recommend that the salary of Mr. James Dalrymple, the new manager of the tramways, be fixed at £1,000 per annum.

The Bury Tramways Committee have resolved to increase the salary of Mr. W. A. Turnbull, overhead equipment clerk of works, from £2 to £2. 5s. per week. We also understand that the salary of Mr. Clough, as tramways manager, has been fixed at £250 per annum.

Mr. Walter Binns, A.M.I.E.E., A.M.I Mech.E., engineer and manager of the Reading Corporation tramways, has had his salary increased from £300 to £400 per annum, rising by two annual increments of £50 to £500 per annum, upon his agreeing to remain in their service for a period of three years.

Mr. E. Moxon, mains superintendent to the Huddersfield Corporation, has been appointed mains assistant to the Blackburn Corporation electricity department out of 80 applications.

Mr. R. B. Leach, assistant engineer to the Aston Manor electricity works, has been appointed assistant electrical engineer to the Farnworth Urban District Council.

The Leigh Electricity Committee have selected the following short list—W. Ainscough (Leeds), H. C. Caldwell (Altrincham), D. A. Hamilton (Lancaster), B. S. Hornby (Bolton), and A. T. Smith (Bury)—out of the 147 applicants for the post of electrical engineer to the Corporation at a commencing salary of £250 per annum, rising by annual increments of £20 to a maximum of £350.

APPOINTMENTS VACANT.

Electrical Engineer, Worcester Corporation. Salary £400, rising by instalments of £20 per annum to a maximum of £500. Applications by 10 a.m. on 19th inst. See advertisement.

Improver, Peterborough Corporation. Salary 20s. per week. Applications by 16th inst. See advertisement.

Assistant, City and Guilds Central Technical College. Salary commencing at £150 per annum. See advertisement.

Assistant, thoroughly experienced in estimating for switchgear, arc lamps, and the like. Apply to Box 202, *Electrical Engineer* Office. See advertisement.

Draughtsman for high and low tension electrical switchboard apparatus, for large electrical engineering firm in Manchester district. Apply to Box B 76 *Electrical Engineer* Office. See advertisement.

Electrical Foreman, Manchester Education Committee. Wages, £2. 5s. per week. Applications to Mr. J. H. Reynolds, principal, Municipal School of Technology, Sackville-street, Manchester.

Distributing Assistant, Belfast Corporation, £200 per annum Dec. 15.

Junior Assistant Engineer, Hebden Bridge Urban District Council. Dec. 13.

Assistant Shift Engineer, Horsham Urban District Council, £100 per annum. Dec. 13.

LEGAL INTELLIGENCE.

MANCHESTER TRAMWAY ARBITRATION.

The Court of Appeal gave judgment on Saturday on the appeal arising out of the arbitration between the Manchester Carriage and Tramway Company and the Swinton and Pendlebury Urban District Council.

The latter appealed from a judgment of Mr. Justice Channell on a special case by the late Sir F. Bramwell as to whether the District Council were to purchase any of the company's depôts outside their district. The purchase clause of the Tramways Act provides that the promoters shall sell to the purchasing authority their undertaking, or so much of the same as is within such district, upon the terms of paying the then value of the tramway and "All lands, buildings, work, material, and plant of the promoters suitable to be used by them for the purposes of their undertaking within such district."

The motion which rose upon the appeal was whether the words, "Within such district," qualified the word "undertaking," so that a depôt outside the Council's district, but suitable to and used for the purposes of such part, was within such district. The special case found as a fact that the Church-street depôt in dispute was "suitable and used" with the undertaking, and Mr. Justice Channell upheld the special case. Hence the present appeal.

Their Lordships allowed the appeal, holding that it had not been shown that the District Council were under an obligation to pay £24,000 for the Church-street depôt.

NERNST ELECTRIC LIGHT COMPANY.

Reduction of Capital.

Mr. Justice Swinfen Eady last week heard a petition by the company for reduction of capital. The original capital of £320 000 consisted of £140,000 preference shares and £180,000 ordinary shares. Upon the acquisition of patent rights the company had spent £270,000, of which £65,000 was paid in cash and the remainder in shares. The whole of the £320,000 stock had been issued, but 260 preference shares had been forfeited through non-payment of calls.

Mr. Eve, K.C., stated that the price paid for patent rights seemed out of all proportion to their intrinsic value, and as the company hoped that they had now entered upon a dividend-paying career, they were desirous of getting rid of the incubus of a large amount of capital which was not represented by available assets. Resolutions had been passed in favour of reducing the capital to £90,000, in 90,000 ordinary shares, preference shares to be extinguished. In regard to the patents, the royalties paid by licensees in this country were estimated to be worth £20,000, leaving £258,000 for the original patent, according to which the company were practically unable to manufacture saleable lamps at all. What they had to do was to purchase them from a Berlin company, who had some secret process by which marketable lamps were made. The value of the patent, which expires in 1915, was estimated at £40,000 beyond the £20,000 from royalties.

Documentary evidence having been read, his Lordship sanctioned the reduction.

TRAMWAY ACCIDENTS.

In the Civil Court of Leeds Assizes Mr. Justice Darling heard three cases in which negligence was alleged against the servants of the Bradford Corporation.

The first of these actions was brought by Harry Dexter, who claimed damages for personal injuries caused on May 26 last by a collision between a tramcar and a furniture van that he was driving. It was stated that the driver of the car disregarded the plaintiff's warning not to attempt to pass the van at a narrow part of the road, and the collision ensued, with the result that the plaintiff was thrown to the ground and rendered unconscious. For the defence it was contended that there was room for the car to pass, and that the accident happened through the plaintiff allowing his horse to swerve. A verdict for the defendant Corporation was returned by the jury.

In the next case a youth named Arthur Phillips Hampshire sought to recover damages for personal injuries caused by a tramway accident on May 4 last at Shipley. On that day the Bradford Exhibition was opened, and Bradford trams were running over the line from Shipley to Saltaire, which had been taken over from a private company two days before. The plaintiff, it appeared, was riding on the top of the car along this line, on which the overhead wires were 2ft. higher than in Bradford, so that the trolley pole did not hold tight up to the wire. While passing over the points the trolley pole came off the wire and caught in a span wire, and the iron standard was wrenched off the top of the car. The plaintiff was knocked down and had his nose broken. Liability was admitted, and the jury assessed the damages at £150.

The third action was brought by John Gerrard Hogan, a retired mill manager, who claimed for the loss of his wife, 72 years of age, who was run over by a tramcar on Aug. 19. The case was withdrawn, the plaintiff agreeing to an amount of compensation offered by the Corporation.

TRAMCAR INSPECTOR ASSAULTED.

At Cardiff Police Court last week Charles Morris, labourer, was summoned by William John Davenport, an inspector of the Cardiff Corporation tramways, for assault.

Mr. F. W. Ensor (from the town clerk's office) conducted the prosecution.

According to the complainant's evidence, defendant's conduct was offensive and brutal. Complainant said that on the afternoon in question he was on a car from Clarence-road to town. Witness was inspecting the tickets, and defendant, when it came to his turn, used abusive language. Although told that if he didn't behave he would have to leave the car, defendant continued his objectionable conduct and language. At Penarth-road junction defendant refused to leave, and struck witness in the face and then on the side of the head. Detective Harris and Police-constable Rich appeared upon the scene, and in their presence defendant again caught hold of him and dealt him several hard knocks in the ribs. He fell against a hand truck, his head striking the wheel. Defendant refused his name and address to witness and to the police.

Defendant was fined £5, including costs, or one month.

HEAVY DAMAGES.

At Liverpool Assizes on Tuesday Dr. Hall, medical officer of Prescot Union, was awarded £1,000 damages for injuries sustained by his forcible ejectment from a tramcar belonging to the Corporation, whereby his leg was fractured. The plaintiff's offence consisted in holding in his hand a cigar which was smouldering, which the conductor alleged was an infringement of the by-law against smoking. The plaintiff refused to put out the cigar or quit the car, and was forcibly ejected.

Mr. Justice Walton held that the plaintiff's conduct was obstinate and stupid, though it did not justify recourse to unnecessary violence.

AUTOMATIC TELEPHONE PATENTS.

A public enquiry was held before Mr. Registrar Hood on Tuesday into the promotion and failure of the Automatic Telephone Company (1903), Limited, against which a winding-up order was made last March upon the petition of shareholders. The statement of affairs shows liabilities £1,175, against assets £4,185, but a deficiency of £10,051 as regards shareholders. Mr. H. Brougham attended as official receiver, Mr. Harry Dobb for shareholders, and Dr. Counsel for Mr. Max Margowski (the late managing director). After evidence had been taken from Mr. Margowski, the enquiry was adjourned *sine die*.

COMPANIES' MEETINGS AND REPORTS

BRITISH WESTINGHOUSE.

The fifth annual general meeting was held on Tuesday at Hamilton House, Mr. William I. Buchanan presiding. The report for the year ending July 31 appeared in our last week's issue.

The Chairman, in moving the adoption of the report, stated that what he might say in this connection would be based upon two or three points. In the first place, the formation of their Company and the building of their plant at Trafford Park were evidently not the result of immature thought on the part of Mr. Westinghouse or of his associates, but of their well-considered, careful thought, founded on their experience in like enterprises; secondly, the Company was evidently not formed or the works built for the present, or for the next two or five years, but upon what must have been a conscious belief on the part of those who initiated the undertaking, and who still believed in the correctness of their view, that it would not be found too large for the work which would one day come to it; and in the next place results secured during the early years of the "life" of any large industrial enterprise were not conclusive as to what its future would be. The expected development which had been anticipated had not yet taken place, and an abnormal expenditure both in the original outlay for the plant and in its completion and operation had, therefore, naturally resulted. It was believed at the time that important electrical developments in Great Britain—especially in methods of transportation and in connection with electrical power distribution—were within sight. While this belief had not yet been fully borne out by results, he did not think any person conversant with the trend of affairs to-day would deny that a radical change in the present methods of transportation in this country—within certain wide limits, at least—was to-day a "self-evident certainty"; but whether this would take place within the next year or within the next two, three, or five years, he was not willing to hazard an opinion. The character of some of the chief work undertaken by the Company more than a year ago had also been a factor in the results attained; he referred particularly to the great turbines now being completed, the first of which were just beginning in London to do their work of furnishing power for the underground railways. This work was so entirely new in every way, and involved such great risks in construction and operation, that every precaution which prudence could suggest was demanded of their staff at the works. The development charges thus brought about were of necessity large. The production of similar work in the future would become but a matter of manufacturing, instead of one of origin, development, and manufacturing. Industrial conditions had been very adverse during the last year or so. But there was another competitive element, far-reaching in its results, which had entered into this matter of the prices the Company had been obliged to meet—namely, competition from manufacturing concerns outside Great Britain. His own view of this phase of competition and of its results was that it was not so much the amount of business contracted in Great Britain by German and other Continental electrical manufacturing concerns—very large as that was—but rather the influence which the presence of this competition in all important tenders exerted upon prices quoted by British manufacturers, since the logical sequence to be drawn from such a condition was that it became necessary for the sales department of a British company to try in advance to discount this unknown outside price, with the net result that much lower prices were made by

Digitized by Google

British companies in such circumstances than would be the case were the competition they had to meet limited to Great Britain alone. This feature of competitive business at home being embodied in their public policy was hence beyond the control of any Board. He could not, however, refrain from expressing his individual belief that it was a matter of more importance to manufacturing interests here, and especially to such as their own, than appeared to him to be realised by many. To those who directed large specialised companies like theirs, which had to meet this wide competition to a greater extent than did others, there was but one course left open—namely, courageously to use their very best endeavours to meet the situation by economical work, and then to go ahead and secure, at the best obtainable price, as large a proportion as possible of the work offered. Alluding to the Company's investments in other concerns, he referred especially to the Traction and Power Securities Company (in which this Company hold shares to the amount of £250,000, of which £175,000 has been paid up) and to the Clyde Valley Electrical Power Company—the largest power development company, he thought, which had been thus far undertaken in Great Britain—and remarked that it was on the building of such large electrical undertakings as these that electrical manufacturing concerns such as the Company's must in a considerable measure depend for their success. He had been asked to say something with regard to the condition of the Company's property at Trafford Park in view of the auditors' reference to the matter of depreciation thereon. Concerning the buildings and grounds, he had already stated that in the accounts under review a considerable sum had gone into their completion, but quite apart from this special care had been exercised in the upkeep of the buildings. He held that the opinion of the Board was justified, in the circumstances, that no depreciation was necessary in making up last year's accounts. With regard to their large machine tools and their general plant equipment, these had also been maintained at a very high degree of efficiency, and during the year £25,490 had been charged to general expenses in connection with their maintenance and with improvements in them. Many new tools were also added during the year. The Board, therefore, thought that the £10,500 charged for depreciation under this heading was a fair adjustment. In the matter of patterns and dies and small tools, quite outside the sum of £19,033 charged against their upkeep during the year, the Board in the middle of the year adopted the policy of charging all dies, patterns, small tools, etc., direct to factory expenses or to a particular contract. The sum thus charged to factory expenses during the six months referred to amounted to £20,346. It was, moreover, clear that the general subject of depreciation would more properly come up for consideration when the profit warranted the payment of a dividend. He afterwards referred to the measures which had been taken for reducing general expenses and the cost of manufacturing, and stated that much had been accomplished in this direction. The cost price at which work was now being produced in the factory was steadily dropping in all cases, and it was nearing a normal mark in several. This was because the workmen were now becoming efficient units in a whole, and the organisation more coherent and better co-ordinated for the work in hand through the decrease in its *personnel* which had been found possible. As to what the future might bring in the way of business he could not say, nor would he hazard an opinion. It seemed fair to assume, however, that if the development in electrical traction in Great Britain to any measurable degree kept pace with the present outlook in the same direction in the United States, there should be, with the gains which seemed likely to take place in the demand for electrical apparatus in the British Colonies, sufficient work in the near future for the electrical manufacturing concerns in Great Britain. Their plant and organisation at Trafford Park were equipped to this end, The American shareholders had during the last year invested £900,000 more in the business without asking a penny from the British shareholders.

Mr. J. H. Lukach seconded the motion.

The **Chairman**, replying to questions, stated that he was unable to say whether another company which had been mentioned were buying stock in this Company or not, but, so far as he knew, he could absolutely deny the statement. The average interest paid to their bankers and others had been 4½ per cent. On July 31 last their sundry creditors were £374,678, and their temporary loans stood at £200,750; on Oct. 31 the sundry creditors were £248,562, and there were no temporary loans. The cash at the bankers now amounted (on that morning) to £90,006, and there were unpaid vouchers in the offices representing £45,776. The goods in process of manufacture on Oct. 31 amounted to £334,397, and they had in finished products at the factory that day a very much larger amount than they required or than they ought to have, and every effort must be made to reduce this amount, which now stood at £251,846. A great deal of this work had been ordered by those who, owing to lack of accommodation, had so far not been able to accept delivery.

The report was adopted.

WEST INDIA AND PANAMA TELEGRAPH.

The ordinary general meeting was held at Winchester House, Mr. W. B. Kingsford presiding. Particulars of the report for the half-year ending June 30 appeared in our last week's issue.

The **Chairman**, after reviewing progress, moved the adoption of the report and the payment of 7s. per share on account of arrears of dividend on the first preference shares.

Mr. Henry Holmes seconded the motion.

A short discussion followed, in which **Mr. W. H. Birks** and **Mr. Edmonds** supported the policy of the Board in transferring the interest on the reserve fund investments to revenue.

Mr. Thorpe suggested the advisability of placing the interest to reserve, observing that in view of the depletion of that fund year by year to provide for the renewal of cables, it was desirable to adopt some such automatic mode of maintaining the reserve at a proper level.

The **Chairman** pointed out that if the interest were placed to reserve, as was formerly the practice, the effect would be to cause the dividends on the first and second preference shares to fall yet further into arrear. In reply to a question, he stated that up to June 30 last the Company's traffic receipts showed a decline of about £500, and he was informed by Mr. Quick that so far during the current half-year there had been a decrease in the receipts of some hundreds of pounds.

The motion was agreed to unanimously.

ARON ELECTRICITY METER.

The seventh ordinary general meeting was held at Winchester House. Particulars of the report for the year appeared in our issue of the 25th ult.

Mr. H. Hirst, who presided, moved the adoption of the report, which, he said, was a record of progress. The profit and loss account showed a gross profit on trading of £23,256. The business which the Company had done since Oct. 1 justified the Board in anticipating a continuance of sound trading during the coming financial year.

The report was adopted.

GENEVA TRAMWAYS.

The second annual general meeting was held at Salisbury House, the Hon. Arthur G. Brand presiding. An abstract of the report appeared in our issue of the 25th ult.

After reviewing the history of the Company during the past two years, the **Chairman** predicted a substantial increase in receipts during next year, as the traffic was showing great improvement. It would, however, be necessary to rearrange their finances before long.

BRITISH ALUMINIUM.

An extraordinary general meeting of the shareholders was held for the purpose of considering resolutions authorising the funding of the arrears on the 7 per cent. preference shares, the borrowing of £300,000 on debentures to be called "Loch Leven Debentures," and the creation of £190,000 additional ordinary capital.

The resolutions were carried.

ISLE OF THANET ELECTRIC TRAMWAYS AND LIGHTING.

The Company report that the total receipts for the year ended Sept. 30 were £37,620, and the net profit £13,493. In order to pay interest, the dividend on the preference shares, and a few minor charges, an additional sum of £2,454 was required, which was taken from the unappropriated balance, reducing it to £1,558.

NEW COMPANIES REGISTERED.

Birmingham and Midland Motor-Omnibus Company, Limited. Capital, £60,000. Objects: to adopt an agreement with the Birmingham Motor Express Company, Limited, and to carry on the business of motorcar, omnibus proprietors, and vehicle builders, engineers, manufacturers of accumulators, dynamos, and other apparatus for the manufacture and equipment of such vehicles, etc. Registered office: Winchester House, Colmore-row, Birmingham.

Liens Registered.

United Electric Light and Power Supply Company, Limited, Manchester.—Lien registered Nov. 25 for £450 6 per cent. debentures, part of £3,000. Amount previously issued, £2,375. No trustees. Charged on the undertaking and all the property, present and future, including all the buildings, machinery, and other property at Guimarães, Portugal, and also the uncalled capital.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Guirgia (Roumania).—Tenders are required for the electric lighting of the town. Particulars from the town's secretary. Tenders by Jan. 28, 1905.

Salamanca.—The Municipality require tenders for public electric lighting of the town. Tenders by Dec. 12 to above or to Direccion-General de Administracion, Madrid.

Edinburgh.—The Corporation invite tenders for the electric lighting installation at the branch free library, Morningside-road, Edinburgh. Tenders by Dec. 14. See advertisement.

Erith.—The Urban District Council invite tenders for motorcars, trucks, motors, and equipments, track sweeping and watering car. Tenders by Dec. 19. See advertisement.

Almendrajo (Spain).—Tenders are invited for public electric lighting for 10 years. Particulars may be obtained from the Secretary of the Ayuntamiento of that town. Tenders by Dec. 22.

Swindon.—The Corporation invite tenders for the supply and erection of one 300-kw. steam dynamo, or, alternatively, one 400-kw. steam dynamo. Tenders by Dec. 20. See advertisement.

Madrid.—The Public Works Branch of the Department for Agriculture require tenders for construction and working of an electric tramway between Azeritia and Zumaya. Tenders by Dec 10.

Bradford.—The Corporation invite tenders for the supply of miscellaneous stores required by the tramways department during the year ending Dec. 31, 1905. Tenders by Dec. 17. See advertisement.

Digitized by Google

Caen (France).—The Prefect requires tenders for concession of a tramway from Ryes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1, 1905.

Stoke-upon-Trent.—The Guardians invite tenders for proposed electric lighting of a portion of the workhouse premises. Tenders to be delivered to Mr. C. Daniel, clerk, Union Offices, Stoke-upon-Trent, by 9 a.m. on Dec. 14.

Rochdale.—The Corporation invite tenders for high-tension three-phase switchgear and extensions to the low-tension continuous-current switchboards. Tenders to Mr. Wm. Henry Hickson, town clerk, by 27th inst. See advertisement.

Madrid.—The call for tenders for the service of the electric lighting of Almendralejo was without result. The conditions of contract have, therefore, been modified in certain respects, and tenders are to be called for to be opened on Dec. 22.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient fo the number of lamps required. Tenders by Jan. 15, 1905.

London, S.E.—Tenders are invited for the erection of an electrica traveller to lift 12 tons over a span of 40ft. Persons desirous of tendering should send their names on or before Dec. 10 to B. E. Nightingale, Albert Works, Albert-embankment, Lambeth, S.E.

Fulham.—The Council require tenders for the supply and erection of a 3,000-volt steam alternator of 1,000 kw. capacity, coupled to a Belliss engine, at their generating station, Townmead-road. Tenders to Town Clerk not later than 12 noon on Dec. 20. See advertisement.

Johannesburg.—The Municipal Council invite tenders for two 35-ton electric overhead travelling cranes and transformer pillars and switchgear. Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W., and received by them not later than Dec. 27.

Pontefract.—The Guardians invite tenders for extensions to present installation of electric light at the new workhouse buildings. Tenders to be delivered or sent to Mr. T. J. Amies, clerk, by 9 a.m. on Dec. 10, at the Poor-Law Offices, Pontefract.

Southend-on-Sea.—The Corporation invite tenders for additional plant for their generating station, comprising the following: two boilers, one steam dynamo, one fuel economiser, two electrical feed pumps. Tenders to be delivered at the offices of Mr. William H. Snow, town clerk, Southend-on-Sea, by Dec. 21.

Glasgow.—The Corporation invite tenders for the supply of 100 electric motor equipments and spare parts for same. Specification, etc., can be obtained on application to Mr. James Dalrymple, general manager, 102, Renfield-street, Glasgow. Tenders must be lodged with Mr. James G. Monro, town clerk, City Chambers, Glasgow, by 10 a.m. on Dec. 22.

Stockport.—The Guardians invite tenders for providing and fixing electric light (wiring only), telephones, and bells required at the new infirmary, Stepping Hill. Plans and specification may be seen and all other information obtained from Mr. W. H. Ward, architect, Paradise-street, Birmingham. Tenders to Mr. Charles F. Johnson, clerk, and to be delivered by 10 a.m. on Dec. 12.

Valladolid.—Tenders are required for the public lighting by means of electricity of the city of Valladolid. Fifteen hundred incandescent lamps of 17 c.p. will be required. The concession will terminate on Dec. 31, 1911. The annual payment to the concessionnaire will be about £965. A deposit of £48 is required to qualify any tender. The adjudication will take place at 11 a.m. on Dec. 26, at the Casa Consistorial, Valladolid.

Ilford.—The Urban District Council invite tenders for the installation of a telephone fire-alarm system on the double or metallic principle. Particulars and form of tender may be had on application to Mr. H. Shaw, A.M.I.C.E., surveyor, Town Hall, Ilford, on payment of a deposit of £2. 2s., which will be returned on receipt of a bona fide tender. Tenders, addressed to the Chairman, must be sent to Mr. John W. Benton, clerk, town Hall, Ilford, by Dec. 19.

Perth (Australia).—Tenders are invited by the Duputy-Postmaster-General for the supply of the following telephone material; 19½ miles 26-pair lead-covered cable, dry core, to standard specification No. 7; 5,000 paper sleeves, 3in. long by $\frac{3}{16}$in. diameter; 350 yards paper strips, 2in. wide. Conditions, etc., may be obtained at the General Post Offices at Perth, Adelaide, Melbourne, Sydney, Brisbane, and Hobart. Tenders by Dec. 28.

Shanghai.—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

Bromsgrove (Worcs.).—The Visiting Committee invite tenders for the supply and erection at their new lunatic asylum of the following plant: (Section A) engines, dynamos, booster, and steam services; (B) storage battery and accessories; (C) main switchboard, ring main, feeders, distribution boards, wiring, lamps, and accessories. Specification, etc., may be obtained from Mr. Robert J. Oliver, clerk of the Visiting Committee, Shirehall, Worcester, on payment of £5 for each section of the work as above, which will be returned on receipt of a bona fide tender.

Cardiff.—The Corporation invite tenders for the following plant for the extensions to their power station on the extra high-tension three-phase system—viz.: two 1,600 slow-speed vertical engines, two 1,100-kw. three-phase alternators, four Lancashire boilers with accessories, steam and other piping, switchboard gallery and staircase, extensions to central service gangway, extra high-tension three-phase feeder cables. General conditions, specification, and form of tender may be obtained on application from Mr. Arthur Ellis, M.I.M.E., M.I.E.E., borough electrical engineer and manager, Central Offices, The Hayes, Cardiff. Tenders to be delivered at the office of Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff, by Dec. 19.

Madrid.—Tenders are invited for the public lighting by means of electricity of the town of Villanueva y Geltru for a term of 10 years. Twenty-four arc lamps of 500 c.p. and 239 incandescent lamps of 20 c.p. will be required. The concessionnaire will be allowed to supply private individuals without payment of a municipal tax subject to his supplying, free of charge, the Casa Consistorial with 75 kw. per month. He will be required to maintain a duplicate set of machinery in order to avoid the possibility of the town being left in darkness through a breakdown. The annual payment (upset price) to the concessionnaire will be 23 145 pesetas (about £678). The adjudication will take place on Dec. 24. A deposit of £68 is required to qualify any tender.

Madrid.—The *Gaceta de Madrid* of Nov. 9 publishes a notice inviting tenders for the construction and working for 60 years of an electric tramway between Azcoitia and Zumaya (Province of Guipúzcoa), in accordance with certain conditions set out in the *Gaceta*. An application for this concession has already been received from Don Dionisio Sorseta Garcia who, at the same rates, will enjoy certain preferential rights over other tenderers. The competition will turn, in the first place, on the reduction of the tariff fixed for the conveyance of passengers, etc.; in the event of equal terms being offered, it will turn on a reduction of the period of concession. Adjudication of tenders will take place before the Director-General of Public Works, Madrid, on Jan. 10. A deposit of 16,297 pesetas (about £475) is required to qualify any tender

Manchester.—Tenders are invited for (Contract C) switchboards, mains, feeders, etc., for supply of electric current for power and lighting, and for arc lamps, etc., in connection with the new dock works, Salford, for the Manchester Ship Canal Company. (Contract D) for mains, feeders, etc., for the supply of electric current for power and lighting, and for arc lamps, etc. Drawings for both contracts can be inspected and copies of specifications, bills of quantities, and forms of tender can be obtained at the office of Mr. W. H. Hunter, M.I.C.E., chief engineer to the Manchester Ship Canal Company, 41, Spring-gardens, Manchester, on payment of a sum of £3. 3s., which will be returned on receipt of a bona fide tender. Tenders to be addressed to Mr. F. A. Eyre, secretary, Manchester Ship Canal Company, 41, Spring-gardens, Manchester, by 10 a.m. on Dec. 22.

RESULTS OF TENDERS.

Hammersmith.—The Council have ordered eight additional 100 kw. transformers from the British Electric Transformer Manufacturing Company, Limited, at £120 each.

Cheltenham.—The tender of the Pfluger Accumulator Company has been accepted for the supply of a battery of 265 cells at £827. 12s. plus £3. 3s. 6d. for each extra cell required.

Rotherham.—The Corporation have accepted the tender of Messrs. Smith Bros. (Rotherham), Limited, High-street, Rotherham, for wiring the new isolation hospital buildings in Badsley Moor-lane.

Southwold (Suffolk).—The Hart Accumulator Company, Limited, Stratford, E., have been awarded the order to supply 110 of their standard lighting type cells to replace the existing battery at the electricity works.

Woolwich.—The tender of Callender's Cable and Construction Company, Limited, at £8,493. 6s. 8d., has been accepted for the supply, laying, etc., of the extra high-tension mains required for the Shooters Hill and Eltham extensions.

Hammersmith.—The following tenders have been recommended for acceptance for the electrical installation at the new workhouse and infirmary buildings: Scott, Anderson, and Co., Royal Insurance-buildings, Sheffield, electric wiring, £6,700; Suter and Co., 66, Berners-street, W., transforming apparatus, etc., £2,061. 12s. 6d.

Belfast.—The City Council have decided to accept Messrs. J. G. White and Co.'s entire contract for the electrification of the tramways at £543,404. 4s. 9d., which is £5,500 more than the same work would have cost had the contracts been placed in separate sections as recommended by the Tramways Committee, and reported in our last issue.

Aberdeen.—The Electricity Committee have recommended the following tenders for acceptance (but the whole matter has been referred back) for the proposed alterations on the municipal buildings: Pratt and Keith, electric lighting, £255; Aberdeen Electrical Engineering Company, Limited, telephones and bells, £161; Otis Elevator Company, Limited, electric lift, £540.

Hammersmith.—The Borough Council have received the following tenders for cables and street boxes:—

Western Electrical Company (accepted)	£2,375	5	10
Henley's Telegraph Works Company, Limited	2,465	3	0
Callender's Cable Construction Company, Limited	2,493	6	8
Imperial Engineering Supplies Company, Limited	2,533	4	0
Siemens Bros. and Co., Limited	2 604	9	0
Electrical Company, Limited	2,656	5	0
W. F. Dennis and Co.	2,905	0	0
St. Helens Cable Company, Limited	3,196	1	8
Lucy and Co., Limited	3,485	6	8

Sale of Plant.—In consequence of the opening of the new borough electric lighting station, the Bridlington Corporation have for sale the electrical plant which has been in use in connection with the lighting of the Prince's-parade. Full particulars appear in another column.

Digitized by Google

BUSINESS NOTES.

TRACTION.

Leeds.—It has been decided to extend the Swinnow-road lines.

Kilmarnock.—The Corporation tramway system is to be opened to-morrow.

Portsmouth.—A service is to be run between the Floating Bridge and Copnor.

Bradford.—The Tramways Committee contemplate measures for materially expanding their parcels traffic.

Islington.—The Borough Council refuse to assent to the London County Council employing the overhead system.

Spain.—The Bilbao Santander Railway Company, which owns the line from Bilbao to Las Arenas, proposes to transform same to electric traction.

Barking.—An important extension of the electric tramway system is being made by the Barking Council, which is linking up through Barking the tramways of East Ham and those of the Ilford District Council.

Crewe.—Rival promoters have applied for the Council's approval to the introduction of an electric tramway and a service of motor omnibuses respectively. A decision has been deferred pending enquiries.

Electric Traction on Railways.—It is now reported that the Brighton Company have practically decided upon the electrification of their suburban lines, and that the experiment will first be tried on the Victoria-to-Peckham section.

Leith.—The Electric Lighting Committee have resolved to extend the Leith electric lighting station, at an estimated expenditure of £7,000 or £8 000, for the purpose of accommodating additional plant for the working of the tramway system by electricity.

Tipton.—It is stated that, as the result of communication between the District Council and the company, the electrification of the line may be expected before long, as the company do not propose to wait until the route from Wednesbury to Dudley has been completed.

South Shields.—The Tramways Committee recommend that the company be given 12 months' notice to terminate its lease (dated Sept. 5, 1900) of the existing tramways on Feb. 1, 1906. The lease was for seven years, terminable by the Corporation at the end of five years.

Croydon.—In reference to the Corporation's opposition to the British Electric Traction Company's application for an extension of time to complete the Mitcham Light Railway, the Board of Trade, in granting a year's enlargement, intimates that no further extensions may be expected without very cogent reasons.

Wednesbury.—Replying to a question at last week's meeting of the Town Council, the Mayor stated that he had been informed that the electrification of the system between Wednesbury and Darlaston would be commenced forthwith. He was also informed that tenders were out and contracts had been entered into for the commencement of the work.

Gorton.—At a meeting of ratepayers a resolution was unanimously carried in favour of promoting a provisional order to construct tramways along Wellington-street, Gorton-lane, and Reddish-lane. The meeting was convened by the District Council. The proposed tram route, when completed, will have the effect of connecting the system of tramways between Stockport, Reddish, Gorton, and Openshaw.

Shoreham.—At the meeting of the Urban District Council a letter was read from the British Electric Traction Company, Limited, to the effect that the company were desirous in every way possible to meet the Council's views. Regarding the commencement of the work of reconstructing the tramways, the Council's wishes would receive most careful attention. It is possible that the company may commence work next month.

Calais.—The Calais Tramway Company are going to convert their system to electric traction, and to extend it. Financially, the proprietors of the Calais lines are working in conjunction with the Dunkirk Tramway Company, who transformed their lines to electricity last year, since when their earnings have increased by 30 per cent. They, too, contemplate an extension of their lines, and also the purchase of more cars.

Musselburgh.—A trial has been made over the entire system, three miles in length, and the result was completely satisfactory. The points were smoothly negotiated, and the spurts of speed and the application of emergency brakes were satisfactory. Mr. W. Bain, local manager, and Mr. F. E Stanley, track and overhead equipment engineer, were in charge of the trial. The Board of Trade inspection takes place to-day, and the inaugural ceremony has been fixed for Monday afternoon.

Bournemouth.—At a meeting of the Corporation a motion was brought forward that the trams should run on Sundays. After considerable discussion, in which strong opposition was manifested towards the proposal, the motion was defeated by a large majority, only four votes being recorded in favour. The Council also decided not to light the main thoroughfares by electric light on Sundays, as this would entail additional Sunday labour at the Corporation generating station, but continue to light the streets with gas on those days.

Colchester.—The receipts from the Corporation tramways, like those from the neighbouring system of Ipswich, seem to be on the down grade. For the week ending Aug. 4 (when the system was opened) the receipts totalled £604. The next week they were £333. Later they reached £361, but since then there has been a progressive decline, and the week ending the 1st inst. produced £133 only. This is a large drop allowing that conditions have not been favourable to travel of late. The diminished receipts have been counterbalanced in a measure by reduced expenses.

Aston.—The report of the Public Works Committee states that the reconstruction of the tramways is now complete. A councillor called attention to the lack of through communication between Birmingham and Aston. In reply, the Chairman stated that there was a 10 minutes' service between Steel House-lane and Witton, but so far as he could understand the Tramway Committee had not come to an arrangement with Birmingham, and was not likely to until the matter of the station bridge was settled. When the bridge was altered he thought they would quickly get over the present difficulty.

Middlesex County Council.—The tramway route from Cricklewood to Edgware, a distance of five miles, was opened on Saturday. The new line has been constructed by the Middlesex County Council, acting with the Metropolitan Electric Tramways Company, which is working the line under an agreement with the Council. The cars will hold 30 passengers inside and 38 out, and the fare for the entire distance is 3d., with intermediate 1d. and 2d. stages. The system adopted is that of the overhead trolley, and the speed laid down by the Board of Trade regulations varies from 12 to 14 miles an hour.

Bath.—At the meeting of the Rural District Council a member asked that the Council, when giving their attention to the plans of the proposed tramway extensions, should draw the attention of the company to the promise which was made when the plans of the existing routes were approved, that some means of communication should be afforded to those districts which lost their 'bus services through the trams coming there, and were not covered by the present tramway routes, particularly the district of Bathampton. It was resolved to assent to the plans, and to refer in the covering letter to the question of communication with other districts.

Bury.—The Town Council have sanctioned a scheme for the collection and delivery of parcels on the tramway system. Conductors of cars travelling into Bury will now receive parcels at any stopping-place at a charge of 2d. up to 7lb. weight, 3d. up to 14lb., and 4d. for 28lb. Parcels will be distributed from the central office to within half a mile of any part of the system, or forwarded by parcels post or train. Railway parcels will also be collected within half a mile or a mile of the system at additional charges. Many parcels have already been carried. As an alternative route to that along Brandlesome-road for the Ramsbottom tramway scheme, powers are to be sought to construct lines from Tottington by way of Greenmount.

Inquest.—At the Southwark Coroner's Court on Friday last Dr. Waldo held an enquiry into the circumstances attending the death of Christopher Lockley, a cabman. Deceased was killed in an electric tramcar collision. Mr. Preston appeared for the London County Council and Mr. Fowler appeared on behalf of the widow. The deceased was crossing the road in Newington-causeway when an electric car, coming from St. George's Church, smashed into the cab. The cab wheel was struck and the driver thrown to the ground, and the tramcar went over him. According to one witness, there was little traffic at the time. The tram was going at the rate of 12 miles an hour. A passenger stated that the car was going at the rate of six miles an hour. The jury returned a verdict of accidental death, and expressed the opinion that the tram-driver was guilty of some negligence.

Penarth-Cardiff.—At Monday's meeting of the Penarth Urban District Council a resolution was moved that the approval of the Council be given to the scheme of the Penarth Tramways Syndicate for running a service to Cardiff, subject to their agreeing to the conditions already laid down by the Council. There are 11 conditions in all, the chief of which refer to the lowering of Cogan-hill 7ft., the laying of a double line, and the rebuilding of the Ely Bridge. A communication was read from Messrs. Herbert Lewis and Fletcher, the consulting engineers, in regard to the conditions laid down by the Council, which stated that they had not been able to obtain the consent of Lord Bute for the widening and lowering of Cogan-hill. A lengthy discussion ensued, and it was ultimately decided by the casting vote of the chairman that the Council were not prepared to reopen the question under existing conditions.

Glasgow and Paisley.—The decision of Lord Balfour of Burleigh on the claims of Glasgow Corporation and the Paisley and District Tramways Company regarding the proportion of fares payable to each for passengers carried between Hawkhead and Paisley Cross is to the effect that the company are to receive £250 from Glasgow for constructing the siding. The Corporation are to pay to the company the whole fare for each local passenger carried between Hawkhead and Paisley, and, in the case of through passengers, they are to pay two-thirds of a penny on each fare. On the other hand, the Corporation are to receive from the company 3½d. per car mile for working expenses—that is, about 7d. for each car run from Hawkhead to Paisley and back. Beside paying this, the company are to bear the cost of the electric current. The extra expense of checking tickets, etc., is to be borne equally. This award is to last till Dec. 31, 1914. The arbiters' and clerks' fees are to be borne equally.

Dover.—At a meeting of the Town Council the following report was read: "Gentlemen,—I beg to report that I have made a survey and taken levels for the light railway from Buckland Bridge to Minnis-lane, River. In preparing my estimate of the cost of the work, I have included for a double line with the exception of a short length in the narrowest part of Crabble-road. The permanent way in the public streets to consist of a bed of concrete and granite pitcher paving, and the portion through Mr. Edward Coleman's property to be laid on sleepers

Digitized by Google

and ballast. I estimate the cost of the work as follows: land, £750; permanent way, electrical equipment, fencing, etc., £13,892; four new cars, £2,400; providing slipper brakes to existing 18 cars and new trolley standards to eight cars, £624; paving, forming, metalling etc., the streets to be laid out for Messrs. Flint and Tritton, £1,394; cost of obtaining provisional order, legal expenses, etc., £1,500; contingencies, £440—£21,000.—Henry E. Stilgoe." In the course of a discussion which followed, the town clerk said the figures showed a loss of £756 a year. It was eventually decided to apply for borrowing powers.

Blackpool.—The St. Annes and Lytham Tramways Company has intimated to the Corporation that the deposit of a Bill by the company asking for compulsory running powers over the Corporation lines is only a precautionary measure, and the company trust that an agreement may be arrived at which will enable the Bill to be withdrawn. The proposed terms are as follows: The company would, as a temporary arrangement, be prepared to accept running powers over three of the Corporation routes for the period of two years from Jan. 1, 1905, on the basis of all the terms in every respect whatsoever with regard to such running powers being settled by mutual agreement between representatives of this company and representatives of the Corporation, and that any points in difference as to the terms of such running powers and the wording of the agreement should be settled by the sole arbitration of either the manager of the Manchester tramways or the manager of the Liverpool tramways, or if the Blackpool Corporation have some objection to either of these gentlemen, then some other equally competent and experienced person to be agreed upon, who should have power in his sole discretion for the purposes of such two years to determine and settle such differences and the form of the agreement. The period of two years is suggested because the first season would give both sides an ample opportunity of testing such running powers and the terms thereof in actual working, and would afford an opportunity at the close of the 1905 season to either side to bring forward any suggestion for alteration which circumstances might disclose to be advisable, having regard to the experience that one whole season thus obtained and the further period of 12 months would enable the temporary arrangement to be continued until any such new suggestions on either side could be arranged or receive the necessary sanction.

Birmingham.—At the meeting of the Corporation, Alderman Beale, chairman, submitted the report of the Tramways Committee, and moved the approval of their recommendation that the amount included in the Birmingham Corporation Bill of 1905, in connection with the purchase of land for, and the execution of, street widenings, should be increased to £202,200. The Council might possibly look upon this recommendation as something in the nature of an after-thought, but such was not the case. It related to the widening of a portion of Dale End, which both the Tramways Committee and the Public Works Committee had hoped they would be able to do without. There was a short length of street between the junction of Masshouse-lane and Moor-street, and the junction of Chapel-street and Dale End. The Council had sanctioned the proposal to widen the upper portion of Dale End, and also to widen Coleshill-street at the junction of Chapel-street. They originally left this piece out because it was expensive. The Tramways Committee could manage with a single line, which would not necessitate widening, and the Public Works Committee also wished to study economy, but after further consideration by both committees they were convinced that they would not be making a good job by leaving a bottle neck between two portions of the street, and since the Tramways Bill was approved by the Council they had ascertained that one of the largest interests which would have to be acquired for the widening could be so acquired at a figure which the surveyor advised was a reasonable price. The cost of the street widening would be divided between the Public Works and the Tramway Committees. The resolution was approved. Replying to questions, Alderman Beale stated that the Coventry-road route was to be equipped upon the Bristol-road terms. The company would supply the cars, and at the end of the lease the Corporation would take them over at their then value. The Tramways Committee would therefore exercise supervision over the class of cars to be provided. It was quite different on the Dudley-road route. There the Corporation did not take over the cars, and did not exercise the same strict supervision. These cars, when the lease terminated, would go out of Birmingham into outside districts. With regard to the opening of the Coventry-road route he could not give a date. The Corporation had fulfilled its obligation as regarded converting the road some time ago, but he understood the tramways company were waiting for their own electric department to complete its work. It had been understood that the line would be opened before Christmas, and he hoped such would be the case. At a meeting of citizens at the town hall on Wednesday, the Bill to sanction tramway extensions was unanimously approved.

London County Council.—The agenda for Tuesday last contained a recommendation by the Highways Committee that £750 should be voted for a full range of specifications, drawings, and designs covering every detail of tramway rolling-stock with a view to the standardisation of same so as to secure economy and efficiency. The receipts from April 1 to Nov. 26 total £440,811, against £346 552 for the corresponding period last year. Three of the Council's motormen were convicted last week for driving at an excessive speed. The petition of Sion College presented to the City Corporation against the proposal to bring the tramway lines over Blackfriars Bridge states that the petitioners have at considerable expense erected large premises on the Thames Embankment, close to the corner of Blackfriars Bridge, for the purposes of their college; that the site was selected for its comparative quietude, which would be broken by trams; and that the report of the Royal Commission should be awaited. The petition was referred to the Streets Committee. A conference has taken place between representatives of the Highways Committee of the County Council and the members of the Streets, Bridge House Estates, and Special Committees of the Corporation. At a precinct meeting of the parish of Farringdon Without Mr. J. Lewis objected to the proposal to bring the trams across the river. If, he said, trams were once brought into the City, they would never be able to get rid of them. The traffic down Fleet-street and Farringdon-street was sufficient already without adding to it. Mr. J. W. Gaze said he was absolutely opposed to the tram scheme. It meant ruination to the Embankment and to the bridges—Blackfriars Bridge in particular—and was, in his opinion, the thin end of the wedge to start a system of tramways running in the City. Further, if the scheme were adopted, they might be sure that it would mean an addition to the county rate of 3d. in the £. Mr. N. Fortescue, C.C., in dealing with the same matter, said they must be in a certain sense progressive, and study the convenience and wants of the population. One of the first means of doing this was to give every facility for going from one part of London to another. As to the particular question of bringing the lines over Blackfriars, he would not agree to it while the bridge was constructed as at present. Without any difficulty, however, and at a comparatively small cost, the acute angle of the roadway at the juncture with the Embankment might be done away with, and the width of the road at that point nearly doubled, simply by setting back the first stretch of the balustrade at an angle so as to join the Embankment some yards further down, and filling in the space. The entire cost would be borne by the Bridge House Estates Committee. The trams could then be brought over the bridge, and he was sure, would prove a great boon to the public. The ruination of the Embankment had been spoken of, but they should remember that very little of it actually belonged to the City. He intended to put a motion on the paper asking the Corporation to instruct the Bridge House Committee to bring up a scheme on those lines, and he had every hope that it would be well supported. It would be one of the best improvements in the neighbourhead that had been carried out for some considerable time.

Hastings.—The work of construction is about to be commenced, if it has not already started. The whole of the system is expected to be finished by June or July, with the exception of the front line, and when that is started it will only take a week or two, or a month at the outside. The promoters will not wait for this, however. As each section is completed it will be inspected and opened. A line, for instance, might run between Bexhill and Bopeep with those places as termini, until the front line is connected. An employment bureau in connection with the work has been opened, and applications have been numerous. Messrs. Dick, Kerr, and Co.'s wages account for labour only is estimated to come to something like £2,000 a week. A rumour has been current that the gasworks in Queen's-road were to be utilised as a power station, but this is understood to be erroneous. Negotiations are in progress to secure a place for this purpose, but have not yet been completed. There will also be several sub-stations, probably at Ore, Hollington, and Bexhill. The Town Council debated last week the proposal of the company to use the overhead system. The following report was presented by the Tramways and Railways Committee: "The committee have had before them the communication from Messrs. Ashurst, Morris, Crisp, and Co. on the subject of the Hastings tramways, intimating that they are instructed to apply to Parliament next session for a Bill to authorise the front line being worked by overhead traction uniformly with the rest of the system, and at the same time to seek to modify the terms of the Act of 1903 so far as to permit of the lines along the front and London-road being constructed, notwithstanding that the lines 'A' in Upper Church road, and 'B' from Bexhill to Kewhurst, have not been constructed; or, in other words, that the construction of those two lines may be postponed—which communication was referred to them for consideration and report at the meeting of the Council in committee held on Nov. 18, and recommend that Messrs. Ashurst and Co. be forthwith informed that the Council object to the proposal to work the tramways along the front line by overhead traction, and that the committee had decided to defer the consideration of the proposal to postpone the construction of the tramway in Upper Church-road until they have had an opportunity of seeing the Bill." A letter was also read from the Hastings and St. Leonards Ratepayers' Association enclosing a resolution against the overhead system. The report was carried without opposition. Councillor Bones, in seconding, said that the majority of the men in the street agreed in objecting to overhead wires on the front. One councillor drew attention to a clause in the new Bill by which the promoters appeared to be asking for power to do lighting along the route, which, if granted, would greatly affect their own electric lighting operations. The company contend that there is no system in existence which can be successfully worked on the Hastings front line except the overhead wire system. With regard to the decision arrived at by the Town Council, the company's opinion is that it is manifestly unfair of the Corporation to come to any decision on the question of overhead wires on the front before it has received the representatives of the company to explain the purpose of the Bill. The company is going to be the largest ratepayer in Hastings, and during the next six months will spend something like £400,000, and it considers that at the least it is entitled to some consideration. The Bill seeking permission to use the overhead system has not been deposited yet, but the question of the use of overhead wires for the front line does not require the consent of the Corporation. To oppose the Bill in Parliament would doubtless involve heavy expenditure on counsel's fees and other disbursements. The promoters are quite prepared, without any cost to the Corporation, to put up poles of any design the Corporation like, and to put arc lamps on the top of the poles, and so do away with the hideous monstrosities at present along the front. The promoters have not put the clause about overhead wires on the front in the Bill without serious consideration. The company quote the precedents for the overhead system set by other towns. They are desirous of an opportunity of explaining their ideas to the Council, as they think the method they propose to employ for constructing the overhead system along the front will remove any objections on æsthetic grounds.

LIGHTING AND GENERAL.

Hammersmith.—An extension of cables, estimated at £222, is to be made for private supply applied for.

Macclesfield.—The Town Council have now decided to adopt a municipal electricity scheme forthwith.

Private Installation.—The London India Rubber Works are to be lighted electrically. Mr. Frederic H. Taylor is the consulting engineer.

Loughborough.—Twenty-eight applications were received last month for the supply of current, amounting to the equivalent of 2,362 8-c.p. lamps.

Woolwich.—Loans of £5,196 with regard to the gross overspent balance in the electricity works and £16,275 for electricity purposes are to be applied for.

Ramsgate.—A number of letters appear in the local Press urging that at present there is an excellent opportunity for proceeding with the electric lighting scheme.

Wednesbury.—Application is to be made for sanction to a loan of £1,000 for necessary extensions of the main in connection with the electric lighting undertaking.

Bath.—We understand that the Rural District Council have received an offer regarding their powers under the electric lighting provisional order concerning Monkton Combe, Freshford, and Claverton.

Electric and General Investment Co.—The directors have declared an interim dividend at the rate of 10 per cent. per annum on the capital paid up on the ordinary shares, being 1s. per share for the six months ended the 30th ult., payable, less tax, on Jan. 9.

Arbroath.—Further correspondence with reference to the proposed introduction of the electric light into the burgh with the company which has recently been in negotiation with the Council for the undertaking, will be dealt with by the Electric Lighting Committee in the course of next week.

St. Andrews.—The Electric Supply Corporation, Limited, have obtained the Town Council's consent to lay cables for the supply of electric light on both sides of certain streets in the burgh. This is for private lighting, the Town Council not having decided upon street-lighting by electricity at present.

Croydon.—The Lighting and Electricity Committee have re-elected Alderman Miller chairman of the committee and Councillor Rogers vice-chairman for the current year. Mains are to be extended through Elmwood and Lodge roads to Greenwood-road in due course as suggested by the borough electrical engineer.

Kensington.—Notices from the undermentioned electric lighting companies relative to proposed extensions of their mains etc., in the borough have been agreed to: Kensington and Knightsbridge Electric Lighting Company, Kensington Court-place and St. Albans-road; Brompton and Kensington Electricity Supply Company, Stratford-road.

Ashington.—The Northern Electric Supply Company have decided to put electric installations into private dwellings in the Ashington and Hirst district free of cost. A number of the inhabitants have availed themselves of this concession. The large power station in course of erection at Ashington will be completed in the course of a few weeks.

Change of Address.—Owing to the completion of his engagement as consulting electrical engineer with the Stalybridge, Hyde, Mossley, and Dukinfield Tramways and Electricity Board, we are advised that after Dec. 16 all communications of a personal nature to Mr. Alfred H. Gibbings should be addressed, Lynton, Wellington-road North, Stockport.

Burgess Hill.—The Urban District Council have formulated a scheme for the establishment of electric lighting works in the district, and have obtained tenders for the works; but in consequence of the large amount of capital expenditure involved, no further progress has been made in the matter. Under the circumstances they have requested the Board of Trade to allow the provisional order still to remain in force.

Acton.—With regard to the loan of £54,091 for electric lighting purposes, an offer from the Metropolitan Electric Supply Company to advance £25,000 at 3¾ per cent., repayable in 25 years, has been accepted. The clerk is to report to the next meeting as to the taking up of the balance of £29,091. He has also been instructed to apply for sanction to borrow £10,000 for wiring of houses and the supply of electrical fittings.

Retford.—At a meeting of the Town Council on Friday a recommendation to adopt a scheme for supplying the borough with electricity was defeated. Mr. A. B. Mountain explained the scheme, and recommended a minimum expenditure of £5,375. A vote of thanks was passed to Mr. Mountain for his admirable explanation of the scheme, and in replying, he said he hoped the Council would not have cause to repent of the decision they had made.

South Shields.—The statement of sales of current and receipts in connection with the electric light undertaking for the three months ended Sept. 30 shows that the units consumed were 137,250, as compared with 137,148 in the corresponding quarter of last year. The total amount of sales, including public and private lighting and meter rents, was £3,664, compared with £3,470, an increase of £194. The number of consumers advanced to 1,055.

Stock Exchange.—The Stock Exchange Committee has appointed Dec. 9 as a special settling day for the Telephone Company of Egypt, Limited, £60,000 4½ per cent. debenture stock, and also ordered these securities to be quoted in the official list. Application has been made to the committee to allow the Auckland Electric Tramway Company's further issue of £85,100 5 per cent. first mortgage debenture stock, redeemable, to be quoted in the official list.

Ashton-under-Lyne.—The Corporation and the Oldham, Ashton, and Hyde Electric Tramway Company have concluded a renewal of the agreement by which the Corporation supply the whole of the energy for working the tramway for 14 years, commencing next July. The company use over 800,000 units per annum, and we understand that they have recently expressed their entire satisfaction with the supply given them by the Corporation during the past six years.

Economical Combustion.—Erith's Engineering Company, 70, Gracechurch-street, E.C., have just published an interesting pamphlet, entitled "Smoke Prevention and Fuel Economy as a Paying Investment," with the object to explain the principles involved, and the simplest and most efficient methods of attaining success. Amongst the illustrations we note a typical installation of Erith's underfeed stokers on Lancashire boilers at Burnley Corporation electricity works.

Lytham.—An agreement is being drafted between the Urban District Council and Messrs. Foote and Milne, Limited, who are applying for a provisional order to supply electricity. The Urban District Council have decided to inform the Board of Trade that no steps will be taken by them to carry out their obligations under the Lytham Electric Lighting Order, 1900. Consideration of the terms offered by the St. Annes Council to supply electricity has been deferred.

Gloucester.—The City Council have approved a scheme for the extension of electric lighting, and resolved to apply for authority to borrow £15,000 in order to carry out the work. During the first half last year there was a net loss of £1,050, but in the second half a profit of £570 was made. During the first half of the current year the loss was reduced to £290, and the electrical engineer estimates that the profits on the second half will be £767, leaving a net profit of £477 for the year.

Middlesbrough.—The Electric Lighting Committee have re-elected Councillor Charles Dorman chairman for the ensuing year. The electrical engineer (Mr. H. M. Taylor) in his last report states that during November 91,000 units were sold, compared with 66,000 for the corresponding period of last year, 352 tons of coal being consumed against 230 last year. The income amounted to £1,258, and the cost £457, against £919 and £368 respectively a year ago. The cost per unit was 1·2d., as compared with 1·32d. last year. The estimated profit was £801, exclusive of interest.

Edmonton.—The District Council held another special meeting on Friday night to further consider the electricity offers received from the North Metropolitan Electric Power Supply Company, Foote and Milne, Limited, the Industrial Engineering Company, and the National Electric Construction Company, Limited. To a motion that the offer of the first-mentioned company should be accepted, an amendment was proposed in favour of the National Construction Company. Upon a vote being taken, the amendment was defeated by 11 votes to 10. A further amendment was then proposed that the Council should themselves take steps to supply the compulsory area, and this was under discussion when, by the operation of the standing orders, the meeting was adjourned.

Northern Section of Electrical Contractors' Association (Incorporated).—Meetings of the Northern Section of the Electrical Contractors' Association were held at the Queen's Hotel, Stockton-on-Tees, on Saturday, Dec. 3, when Mr. J. McDermott, J.P., Manchester, presided over a representative attendance of members, including Messrs. Cross, Robon, Usher, and Andrews (Newcastle), Hirst (Leeds), Taylor (Huddersfield), Harford (Liverpool), Steinthal and Shaw (Manchester), Brown (Sunderland), Tattersall (Middlesbrough), Geipel and Prescott (West Hartlepool), Watson (Stockton), and W. Cross, hon. secretary. It was reported that the membership was increasing rapidly since the incorporation of the association, and very many matters of interest were discussed.

Edinburgh.—The Town Council on Wednesday agreed to apply for consent to the borrowing of a further sum of £90,000 for capital works under the Edinburgh Electric Lighting Provisional Order, 1891. Their total capital expenditure to May 15 was £845,366. The expenditure for the current year was £60,820, or a total of £906,156, or £46,156 in excess of the amount for which consent to borrow had already been obtained. The additional £90,000 will be sufficient to carry them on very probably for the next two years, bringing the amount sanctioned up to £950,000. The accounts for the past year showed a remarkable progress all along the line. There was an increase of over 1,000 consumers, an increase of over 100,000 8-c.p. lamps, and the output has been increased by 1½ million units. Along with this remarkable increase of business there has been effected a still further reduction in the cost of production, which now stands at ·89d. per unit, although the Council have not the advantage of a traction load.

India.—The Madras Municipal Commissioners have adopted the report of the committee appointed to consider the applications of Messrs. Crompton and Co. and Messrs. Burn and Co. for electric licenses to light Madras and supply power. The committee, after discussing the relative merits of the offers of the two companies decided in favour of Messrs. Crompton and Co., and recommended that the option of purchase should be exercised at the end of 21 years instead of 42 years, renewable every subsequent seven years. The Commissioners forwarded the report to the Government, inviting the latter's attention to the necessity for satisfying themselves by security or otherwise that the licensee is in a position to discharge the duties and obligations imposed on him by license. The proposal for the provision of high-tension transmission from the E. I. R. shops at Lillooah to Howrah railway station yard, and also for the provision of plant for lighting the new joint passenger station and the goods yard with electricity, as also the construction of step-up transformer house at Lillooah, has been provisionally sanctioned at an aggregate cost of about 1 lakh and 24,000 rupees.—*Indian Engineering.*

Digitized by Google

Fulham.—It is proposed that the necessary electric mains for public lighting be laid in Bishop King's-road, and six Nernst lamps substituted for the present gas lamps at an estimated cost of £42. 10s., and that Nernst lamps be substituted for the present gas lamps in Edith-road, between North End-road and Gliddon-road, at an estimated cost of £27. 10s.

Bradford.—The Electricity Committee last night discussed an exhaustive report on the distribution of electricity by the city electrical engineer (Mr. Alfred Blackman), which contains recommendations involving an expenditure of over £40,000. It is estimated that £26,165 will be required for the tramways distribution, including a spare 500-kw. feeder laid into each sub-station; £10,250 for transforming plant at the works; and £4,452 for high-tension feeders for general supply.

Spain.—It has been decided to instal electric lighting at Iznar, Pedrajas, and Olmedo, in the Province of Segovia. The Electro-Minera de Valdemorillo Company has obtained the concession. The three electrical companies at Saragossa—viz., Aragonesa de Electricidad, Electra Peral Zaragozana, and Fuerzas Motrices del Gállego—are about to combine. The shares of the former company will rank for a preference dividend of 6 per cent. for six years, after which the shares of all companies will rank equally.

Dudley.—It has been decided to extend the electric lighting to Hall-street and Dixon's-green, and to apply for sanction to the borrowing of a further £21,000 to cover excess of expenditure of old loans and on account of expenses to be incurred for additional boilers, engines, dynamos, cables, and electrical plant. The result of the working of the first two years was a loss of £390, and of the second two years a profit of £1,452. Last year's profit was £650, of which £505 consisted of the difference between the cost of the gas lighting and the electric lighting of the streets.

Bridgend.—A curious matter came before the District Council last week. The clerk read a letter from the South Wales Electrical Power Distribution Company protesting against the action of a private customer who had connected the lighting mains of his house with the company's mains which are supplying power to the works. It was explained that the customer had been misled by his electrician, who had since left the district, that the estimated loss in revenue had been paid to the Council, and that the Council's electrician having reconnected the place in question with the Council's mains, the matter was now dispensed with.

Hampstead.—The Borough Council have adopted a report of the Lighting Committee stating that they had had under consideration the desirability of using slack coal in the furnaces in connection with the superheaters at the station. They had received a report from the electrical engineer thereon, and had found that a saving would be effected by burning the slack coal mixed with 33 per cent. of coke, instead of using the best Welsh coal. They recommended that 200 tons of small coal and wharf screenings be obtained at the price of 9s. per ton, and that a quantity of coke, not exceeding 50 tons, be obtained at the price of 15s. per ton.

Mexico.—The *Diario Official* of Mexico of Nov. 2 notifies an application by Señor David Reyes Retana for the appropriation of 60,000 litres of water per second from the River Mexcala, State of Guerrero, half this quantity to be used for irrigation, and half for the production of power. The *Diario* of Nov. 4 notifies an application by Señor Gustavo A. Lilliendahl for the appropriation for the production of power of 8,000 litres of water per second from the Rivers Casillas and Pilon, Municipality of Rayones, State of Nuevo León. The *Diarios* may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between the hours of 10 a.m. and 5 p.m. (Saturdays, 10 a.m. to 1 p.m.).

Hastings.—The Electricity Committee have received from the borough electrical engineer a report in which he stated that the high-tension feeder cables which carry the high-tension electricity from these works to the hospital sub-station, and thence to the Shepherd-street sub-station, are becoming too heavily loaded to be safe. On Nov. 18, he said, there was a load of 667 kw. at these works, against the maximum load of 610 kw. on Christmas Eve last year, an increase of 57 kw., and at the same time an increase of 90 kw. on the load for the corresponding evening of last year. To get over the difficulty he proposed to run a $^{37}/_{18}$ cable (this being the largest size that could be got into the present iron pipes) from the works to the hospital sub-station, the length being 1,300 yards, and the cost £450 if all the pipes were in good order; if not, it might be necessary to open at the bad places and repair the pipes, but this cost could not be estimated. The cause of the work was due to the number of consumers that were coming on to the mains in St. Leonards. There are at the present time as many consumers in St. Leonards as there are in Hastings. It has been agreed that the additional cable be put in as suggested, and that the cost be defrayed out of the loan already sanctioned for mains extensions. The Council have made arrangements for the expenditure of £3,417 for purposes of electric lighting and alterations to and extensions of plant. Mr. Alderman Dighton has been appointed chairman of the Tramways Committee.

London Gazette.—At a general meeting of the Cross Electric Engineering and Manufacturing Company, Limited, held at 153, Farringdon-road, London, it was resolved that the company be wound up voluntarily. A general meeting of the Sheffield Electric Advertisements, Limited, will be held at 4, York-street, Sheffield, on Jan. 5, 1905, to receive the liquidator's report, showing how the winding up of the company has been conducted and the property disposed of. The partnership between Walter E. Wort and Charles Hyde Beadle, carrying on business as consulting engineers, etc., at Arctic-chambers, Cowes, Isle of Wight, has been dissolved by mutual consent. A first and final dividend of 2s. 7d. in the £ has been declared in the estates of Frederick William Parkes and Edward Sadleir, electrical engineers and fitters, carrying on business under the style of Parkes and Sadleir at the Dingle, Colwyn Bay, Denbigh. A first and final dividend of 20s. in the £ has been declared in the estate of Frederick William Parkes, electrical engineer and fitter, Etwall, Grove-park, Colwyn Bay, Denbigh (separate estate). A winding-up order has been made out in the estate of the Sir Hiram Maxim Electrical and Engineering Company, Limited, 44, Gillingham-street, Westminster. The partnership between Ernest Gandy and Robert Henry Dewbery, carrying on business as electrical and general engineers at 71, Parliament-street, Nottingham, has been dissolved by mutual consent. The first meeting in the estate of Harry Cooke, electrical engineer, 102, Buccleugh-road, Normacot, Longton, will be held at the Town Hall, Stoke-on-Trent, at 2 p.m., on 19th inst. The last day for receiving proofs in the estate of Albert Smith, electrical engineer, and lately trading as the Electric Motor Supply Company at 54, Houndsgate, Nottingham, is 22nd inst.

West Bromwich.—At a meeting of the General Purposes Committee of the Town Council last Friday, a report was presented by the Electricity Committee with reference to the complaints made against Alderman S. Pitt (chairman of the Electric Lighting and Power Committee) and the foreman fitter. This, according to the *Birmingham Post*, stated that the memorial received from the men at the electricity works on the subject might be divided into two heads—viz: (1) the chairman's alleged interference and annoying visits to the works; and (2) the alleged undue preference given by him to certain employés. In reference to the first head, the committee had to remember that the electrical department was a new undertaking, and whatever chairman had been appointed he would have felt it incumbent upon him to pay very close attention to the establishing of so important a branch of municipal work. The chairman had given an immense amount of time to the development of the undertaking, and they could quite understand he might have been over-anxious for its financial success. The committee could further understand that some employés who had worked in stations where it had not been necessary for the chairman to take so active a part had found his visits not exactly to their taste. However, this difficulty had now been met by the chairman voluntarily consenting not to make his visits to the works so frequent. They (the committee) felt that the men had absolute cause for their complaints. With regard to the second head, the committee had had before them the man who they had reason to believe was the prime mover in the memorial, and he admitted that if he had known all the facts with reference to the appointment of the foreman fitter, he would not have penned the clause in the memorial alleging undue preference, and he thereupon withdrew it and promised to inform the other men who had signed of what he had done. During the course of the enquiry the committee found that many of the complaints were trivial, and it became very apparent that much of the friction was due to the duties of the men not being properly defined. The report was adopted. Alderman Pitt has again been elected chairman of the Electric Lighting Committee.

Cheltenham.—In order to afford supply to the light railway company to work the extensions now being made, a storage battery and booster is to be purchased, and application made for sanction to a loan of £2,000 for the purpose. The Lighting Committee will be guided by the following policy: (1) no capital expenditure outside the compulsory area without the minimum income being secured, or in the case of new streets, unless the builders undertake to wire the houses which, if connected up, would at least secure that minimum income, or in the case of works extensions or alterations with a view to economy in working, but the committee except from the above special or exceptional circumstances; (2) they will endeavour to reduce cost of production if possible; (3) no further extension of street electric lighting at present; (4) to secure a remunerative return from the light railway, having regard to the capital invested; (5) periodical visits to the works, so as to keep in touch with the concern; (6) no capital expenditure without first obtaining the sanction of the Local Government Board. The light railway company will be charged for traction purposes a flat rate of 2½d. The report of Mr. James Swinburne (which appeared in a previous issue) upon the electric undertaking was considered at the last Council meeting. It was resolved: (1) that in view of the heavy burden upon the ratepayers in order to comply with the statutory requirements as to the provision of sinking fund and payment of interest and the discharge of the accumulated deficit upon the undertaking, the committee cannot at present recommend the Council to provide additional sums by way of depreciation, which they are not legally required to do; (2) that this committee recommend that a rent of £8 per annum be charged the electricity department in respect of the land occupied by the central station; (3) that before deciding as to the expediency of appointing a canvasser, the local wiring contractors be invited to attend a conference with this committee with a view to increasing the demand for the electric light; (4) that further consideration of the recommendations and suggestions contained in the report be adjourned until the committee have before them certain information to be obtained by the electrical engineer. The question as to whether the borough electrical engineer should be required to devote his whole time to the service of the Council, and not be permitted to engage in private practice, also came up for consideration. Mr. Kilgour said that, while not required by the terms of his appointment to devote his whole time, as a matter of fact he had necessarily been compelled to do so during the last five or six years, and he was quite willing to undertake to devote his whole time to the duties of his office. This offer was accepted.

PROVISIONAL PATENTS, 1904.

Nov. 28.

25811. Improvements in means for adjusting the height of pendant electric lamps. Arthur Charles Keeping, 3, Tamworth-road, Boscombe, Hampshire.

Digitized by Google

25801. **Improvements in reversing controllers for use in connection with electromotors.** The Electric and Ordnance Accessories Company Limited, Robert Frederick Hall, and Joseph Richardson Garner, 24, Temple-row, Birmingham.

25817. **Electrical incubator alarm.** Walter James, The Rookery, Thurmaston, Leicester.

25829. **An improved composite material for architectural and other analogous purposes and for electrical insulation.** Salo Wohle and Alice Marian Hart, 27, Chancery-lane, London.

25833. **Apparatus for regulating the voltage of alternate-current generators.** Miles Walker, 7, Skerton-road, Old Trafford, Manchester.

25839. **Improvements in and relating to electrolysing apparatus.** Edgar Leslie Thorp, 139, Queen Victoria-street, London.

25898. **Improvements in and connected with switchboards for telegraphic, telephonic, and other electrical systems.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, Chancery-lane, London. (William Pierson Hammond, United States.) (Complete specification.)

25900. **Improvements in safety fuses.** Arthur George Bloxham, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Roburitfabrik Witten a. d. Ruhr, Germany.) (Complete specification.)

25902. **Improvements in and relating to secondary batteries.** The Ekstromer Accumulator Company, Limited, and Emil Laurence Oppermann, 1, Queen Victoria-street, London.

25903. **Improvements in apparatus for the distribution of electric current.** Claude William Atkinson, 1, Queen Victoria-street, London.

25905. **Improvements in and relating to electromagnetic change speed gear for motor vehicles and boats and other purposes.** Percy William Smith, Norfolk House, Norfolk-street, Strand, London. (Count Alain de Kergorlay, ———.) (Complete specification.)

Nov. 29.

25933. **Improvements in or appertaining to junction and disconnecting boxes for underground electric mains.** Robert Hird Clark, 2, Market-street, Bradford.

25937. **A novel or improved composition to be used as a coating for metallic surfaces for the prevention of corrosion and, if desired, for electrically insulating such surfaces.** Thomas Moore Hickman, Prince's-chambers, Wolverhampton.

25950. **Coin-collecting device and system for telephone exchanges.** Harold Dudley Stroud, 65, Chancery-lane, London. (Complete specification.)

25972. **Improvements in and connected with the protection of conductors and insulation of flexible cords for electrical apparatus.** Sydney Stuart Galsworthy, 10, Cravenhill-gardens, Lancaster-gate, London. (Complete specification.)

25985. **Improvements in means for automatically winding clocks and the like with the aid of electricity.** Georg Hartmann, 18, Buckingham-street, Strand, London.

Nov. 30.

26034. **Improvements in telephonic intercommunication.** John Young, 21, Gloucester-walk, Campden-hill, Kensington, London.

26043. **Improvements in submarine telegraphy.** Isidore Kitsee, 18, Fulham-place, Paddington, London. (Complete specification.)

26063. **Electric current generating and motive-power machine.** Walter Shelverton Frost, 135, High-street, Homerton, London.

26082. **Improvements in dynamo construction.** Henry Leitner and Richard Norman Lucas, 4, South-street, Finsbury, London.

26092. **Improvements in or relating to receiver switches for telephone instruments.** Isidore Bernard Birnbaum and Francis George Bell, 322, High Holborn, London.

26096. **Improvements in controlling systems for electric motors.** Arthur Clarke Eastwood, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, March 21, 1904, being date of application in United States.) (Complete specification.)

26097. **Improvements in magnetic clutches.** Arthur Clarke Eastwood, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, April 1, 1904, being date of application in United States.) (Complete specification.)

26098. **Improvements in electric current-controlling systems.** Arthur Clarke Eastwood, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, June 4, 1904, being date of application in United States.) (Complete specification.)

26099. **Improvements in motor-controlling systems.** Arthur Clarke Eastwood, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, June 10, 1904, being date of application in United States.) (Complete specification.)

Dec. 1.

26124. **Electrical release movement.** Charles Vincent, 142, Great Dover-street, London.

26157. **Improvements in and relating to electric arc lamps.** Ferdinand Nusch, 81 High Holborn, London. (Alfred Cotis, France.) (Complete specification.)

26161. **Improvements in or relating to electrical circuit breakers** William Sherman Toplis, Westinghouse-building, Norfolk-street, Strand, London.

26169. **Improvements in thermal cut-outs.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26170. **Improvements in electric switches or cut-outs.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26171. **Improvements in armature windings for dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26172. **Improvements in electric switches and the like.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26173. **Improvements in paper articles and methods of making the same.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26174. **Improvements in and relating to electric transformers.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26175. **Improvements in electric transformers.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26176. **Improvements in and relating to electric transformers.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. The General Electric Company, United States.)

26179. **Improvements in and relating to percussive tools, particularly applicable to electrically-operated percussive drills.** Percy John Ogle, 1, Queen Victoria-street, London.

26194. **Improvements in dynamo-electric generators and motors.** Ludwig Torda, 40, Chancery-lane, London.

Dec. 2.

26220. **Improvements relating to troughs or conduits for underground electric mains or cables and for similar purposes.** John Wilkinson, 18, Southampton-buildings, Chancery-lane, London.

26260. **Improvements in electric arc lamps.** James Bernard Sipe, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

26262. **Improved magnetic separating apparatus.** Carl Scholl, 6, Lord-street, Liverpool. (Complete specification.)

26269. **Improvements in coils for electromagnets, solenoids, and the like.** James Bernard Sipe, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

26282. **Improvements in switch installations for telephone exchanges and in switches therefor.** Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Akt.-Ges., Germany.) (Complete specification.)

26283. **Improvements in electric meters.** Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Société pour l'Exploitation de Compteurs Electriques Rittener et Cie., Switzerland.)

26285. **Improvements in rotary-field electricity meters.** Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Akt.-Ges., Germany.) (Complete specification.)

26288. **Improvements relating to electrical apparatus for training and elevating heavy guns.** Vickers Sons, and Maxim, Limited, Alfred David Williamson, and Cecil Leslie Sumpter, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

26290. **Improvements in the control of alternating-current motors and in apparatus therefor.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26291. **Improvements in and relating to vapour electric apparatus.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26292. **Improvements in joints between metals and vitreous materials and method of forming the same.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26293. **Improvements in and relating to dynamo-electric generators.** Allgemeine-Elektricitäts-Ges., 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 3, 1903, being date of application in Germany. (Complete specification.)

26294. **Improvements in electric brakes.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Digitized by Google

26295. Improvements in electric control systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

DEC. 3.

26327. Improvements in electric switches. Thomas Henry Large, 154, St. Vincent-street, Glasgow.

26331. A guard for electric cars and such like for the saving of life. Fred Darnton, 11, Duke-street, Millfield, Sunderland.

26367. An improved system of wireless telegraphy. William Phillips Thompson, 6, Lord-street, Liverpool. (Gesellschafc für Drahtlose Telegraphie, Germany. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 22, 1904.

1903.

24220. Apparatus for lighting gas lamps by electricity. Gergacsevics.

25765. Electricity meters. Cervera.

25886. Coin operated or controlled electricity meters. D'ck.

26124. Apparatus for controlling and operating the points of electric railways and tramways. Stewart, Turner, and Dixon.

26513. Canopy trolley standard for electric tramcars driven on the overhead system. de Macedo.

27893. Controllers for electric motors. British Thomson-Houston Company, Limited. (General Electric Company.)

1904.

821. Systems of electric motor control and controlling apparatus therefor. British Thomson-Houston Company, Limited. (General Electric Company.)

1624. Device for preventing accidents from overhead trolley wires when broken. Mudie.

1968. Motor-control systems. British Thomson-Houston Company, Limited. (General Electric Company.)

2243. Trolleys for collecting electricity. Thomson.

2315. Electrical terminal attachment device. MacIver and Guy.

2397. Construction of trolley wheels or pulleys for collecting electric currents used in overhead electric traction and the like. Carnegie and Beevers.

2449. Emergency brakes for electrically-propelled vehicles, trains, and the like. British Thomson-Houston Company, Limited. (General Electric Company.)

2452. Controlling alternating-current electric motors. British Thomson-Houston Company, Limited. (General Electric Company.)

2453. Controlling alternating-current electric motors. British Thomson-Houston Company, Limited. (General Electric Company.)

2558. Device for automatically switching off the electric current in an overhead trolley wire immediately a trolley wire breaks or is broken. Payne and Poupart.

2614. Terminals for electric batteries. Prested.

14105. Means for connecting the electrodes of galvanic batteries with their leads. Wiechmann.

16479. Telephone repeaters. Kretzinger.

17528. Apparatus for automatically indicating and registering by electrical means the progress or course of several physical processes or phenomena. Siemens Bros. and Co., Limited. (Siemens und Halske Akt.-Ges.)

18628. Holder or socket for electric incandescent lamps. Stern and Greene.

22964. Gas or vapour electric apparatus. Baker. (Date applied for under International Convention, Nov. 6, 1903.)

23050. Electrical railways. Gill.

23279. Electrical resistances. Aron.

23377. Regulating dynamo-electric generators. Deutsch.

23452. Insulation of coils of electrical apparatus. Moore. (Date applied for under International Convention, Nov. 21, 1903.)

23622. Galvanic batteries. Möllmann.

DESCRIPTION OF ELECTRIC LIGHT AND POWER SCHEMES IN NEW YORK, WITH SPECIAL REFERENCE TO THE WATERSIDE STATION OF THE NEW YORK EDISON COMPANY.*

BY P. S. SHEARDOWN, MEMBER

New York City, the metropolis of the United States, and the largest and wealthiest city in the Western Hemisphere, is finely situated on the islands and mainland at the mouth of the Hudson River. The population of the city in 1903 was estimated by the United States Census Bureau at 3,716,139. In point of numbers, as well as from a commercial and financial standpoint, the city is second to London alone among the great cities of the world. Although owing to the configuration of State boundaries, certain neighbouring cities, such as Jersey City, Newark, and Paterson, lie in the State of New Jersey, and cannot be reckoned as a part of the city in a political sense, they should, nevertheless, be considered in the metropolitan area, and with this addition the total population is increased to about 4,500,000. New York City is divided into five boroughs.

	Area of miles.	Population in 1900.

The borough of Manhattan, which may be called New York proper, comprises the whole of the island of Manhattan. This island is a long narrow strip of land lying nearly north and south. The extreme length of the island is 13½ miles, its breadth varying from ½ to 2½ miles, the total area being 21 miles. It is, of course, this island position of New York which has made land so valuable, and building sites being so costly has brought into existence the skyscraper style of building.

I should like to explain here that except for the old portion of the city, at the extreme south end, the island is laid out quite symmetrically. A commission was appointed in 1807 to lay out the upper streets of the city, and Houston-street was taken as the starting point. It was decided to lay out streets designated by numbers instead of names running east and west, and making 20 to the mile, and to intersect these streets by numbered avenues running north and south, giving seven to the mile. A slight protuberance on the eastern side of Manhattan Island, below Fourteenth-street, was taken care of by short avenues, designated A, B, C, and D. Later on, two additional avenues were added—one to bisect the territory between Fifth and Fourth avenues, called Maddison, and one to bisect the territory between Fourth and Third avenues, called Lexington-avenue. The streets are called "East" or "West," according as they lie east or west of Fifth-avenue. It will thus be understood that a block is a square of buildings bounded on two sides by streets and on the other two sides by avenues. Fourteenth-street is usually taken as making the boundary between up-town and down-town. Down-town, or south of Fourteenth-street, is the commercial or banking and general financial portion of the city; north of Fourteenth-street we come into the shopping, hotel, and theatre quarter; and north of this again we arrive in the more purely residential part. The celebrated Broadway runs more or less diagonally across the island from south to north-west, intersecting most of the avenues and streets.

The electric power stations and systems, which can only be very briefly described in the limits of a short paper, may be divided (A) into those situated on Manhattan Island (area, 21 square miles), and (B) those situated in what may be called the outlying or suburban districts: (A) Power stations and systems on Manhattan Island, the property of (1) New York Edison Company, for the supply of current for public and private lighting, and power for stationary motors, elevators, and fans; (2) the Metropolitan Street Railway Company, for operation of street electric tramcars; (3) the Inter-Borough Rapid Transit Company's Manhattan Railway power station, for operation of overhead electric railway; (4) the Inter-Borough Rapid Transit Company, subway division station, for the operation of electric trains in the new subway. (B) Power stations situated outside Manhattan Island: (5) Edison Electric Illuminating Company, of Brooklyn; (6) Brooklyn Rapid Transit Company; (7) New York Central and Hudson River Railroad Company; (8) New York and Pennsylvania and the Long Island Railroads.

The New York Edison Company and the Waterside Generating Station.

The history of the New York Edison Company is most interesting. They started with and have always kept to a low-pressure direct-current supply network. Originally it was a two-wire, 120-volt system, but is now a three-wire system with 240 volts across the outers. In 1882 they were in possession of the celebrated Pearl-street generating station, which was considered a wonder at the time, and contained six 125-h.p. "Jumbo" generators. Compare this with the new Waterside station of the same company, which has in operation 16 generators, each rated at from 5,500 h.p. to 8,000 h.p., and we are enabled to form some conception of the enormous growth of the business in 20 years. Between these two extremes we have Duane-street station, erected in 1891, with the system of sub-stations by which the city of New York has been supplied. This station is a most interesting one. It was erected before the era of high-potential transmission, and perforce was located near the centre of gravity of the load. Real estate in the heart of the centre of the city of New York City being very expensive, it was necessary to concentrate the power in the smallest space. The form of switchboard first installed in this station, and now in use there and in the other sub-stations throughout the city, is remarkable for its space economy, and was developed by the company's technical staff. In the Vanvleck edgewise system all instruments and regulating switches are read or handled in a vertical plane on the edge of a quarter circle instead of being moved around the face. Besides this station there were numerous other steam generating stations, located in different parts of the system as close as possible to the centre of gravity of the principal portion of the network that it was intended to supply, but owing to the fact that in New York and other large cities the heaviest load in the business section occurs at a different time from the peak load in the theatre and residence section, it would evidently be a most desirable and economical arrangement to have the stations in these districts so connected that each could help the other, utilising the capacity of the generating equipment to the best advantage. This result was attained before the completion of the Waterside station by installing rotary converters and static transformers in Duane-street and the various sub-stations. A net efficiency of over 82 per cent. from direct current to direct current is obtained, and now that Waterside station is in operation the apparatus already installed in the sub-stations is used to transform from high-tension alternating to low-tension direct.

It became evident several years ago that even with this system of mutual help the time was soon coming when the full capacity of the various stations would be inadequate to supply the demands of a rapidly increasing number of consumers; and the multiplication of generating stations being undesirable, plans were drawn for a new station where practically all the current used by the company could be generated, the various stations throughout the city being retained as rotary converter sub-stations. The Waterside station, equipped with the most modern and economical plant, now generates the bulk of the current used on the system, the larger Edison stations—Duane, Twelfth, and Twenty-sixth streets—being used as distributing stations, and as supplementary generating stations during the period of heavy load in the winter months. Some of the less important stations — Vandam, Thirty-ninth, and Fifty-third streets—equipped with less economical generating apparatus, will have their generating equipment removed and will serve as distributing centres. Storage batteries located at all the important distributing centres, in addition to acting as a reserve, will also be used to eliminate the peaks from the local demand, so that the load on the Waterside station will be almost constant during the 24 hours. By utilising the more important generating plants during the months of heavy demand, the larger generating apparatus already installed is used to advantage, additional new investment being saved, which would otherwise be necessary to take care of this capacity.

We notice, then, that in new work the original system of distribution is a direct-current low-pressure one. In the old days, before the development of high-pressure transmission, the feeding of this system was direct current and at low pressure, and under these conditions the economy of having a station located close to the waterside, where rent was low, coal could be obtained cheaply, and the steam plant run condensing, had to be sacrificed because the capital involved in the outlay on copper of low-tension feeders would be a still more costly matter. With the development of the high-pressure three-phase method of distribution it is now possible to have the advantage of a low-pressure network fed economically from a distance by high-pressure currents generated in a station which can be located in a position where the greatest economy in generation can be obtained.

There is, of course, a certain amount of loss, both in capital outlay and in distribution, by using an alternating-current transmission and a direct-current system of distribution, which necessitates practically a double outlay on electric generating machinery, owing to the fact that rotary converters or motor-generators have to be employed at the sub-stations, these also requiring more expense in the way of attendance than if alternating current is used all through. This matter was carefully considered by the Edison Company, who remark in one of their interesting publications: "The arc lamp may be used upon

* Paper read before the Dublin Section of the Institution of Electrical Engineers.

direct or alternating circuits provided the frequency is not less than 40-50 cycles, and although the New York Edison Company has found that satisfactory commercial service can be obtained from alternating-current arcs on ordinary circuits, direct-current lamps are considered, on the whole, somewhat more efficient and reliable. For general industrial use the alternating-current motor, particularly that of the induction type, has reached a stage of perfection making it in every way the peer of the direct-current motor, the absence of commutator and brushes constituting a prime element of simplicity and ready maintenance, although involving a higher first cost. Though constant-speed motors may be designed to operate with satisfaction on alternating currents, yet the direct-current motor is decidedly superior where intermittent service or variable speed is required. As a considerable part of the power used in large American cities is required for elevators and machinery running at variable speed, it becomes almost obligatory to furnish direct current to satisfy this demand. After a careful consideration, therefore, of all the local conditions, the character of the large existing stations, sub-stations, and underground system, the territory to be covered, the present and prospective business, the broadening nature of the electrical industry, and other features none the less perplexing because less indefinite in engineering outline, it was decided to build a large central station generating high-potential alternating-current transmission to sub-stations, and after passing through static transformers and rotary converters to be fed as direct current into the usual low-tension three-wire network. In deciding upon the location of such a central station, the general rule that it shall be located as nearly as possible at the centre of gravity of the system is often modified by the cost of land, availability of water supply, coaling facilities, and various local considerations. The Waterside station of the New York Edison Company is admirably situated to satisfy all these requirements."

There is one other advantage not mentioned in the above statement by the Edison Company which the direct-current network has over the alternating-current network, which is, that storage batteries can be located in the sub-stations, which enable a splendid load factor to be obtained at the generating station, and also give a large reserve of power in case of sudden darkness caused by fog, etc.

THE WATERSIDE STATION OF THE NEW YORK EDISON COMPANY.

The buildings of this station are located on First-avenue, covering the block between Thirty-eighth and Thirty-ninth streets, and running to the East River, an area of 272½ft. long by 76ft. wide. The boiler-house is 276ft. long by 76ft. wide, and is separated by a massive brick wall from the main generating room, which is the same length, but 115ft. wide.

Coal-Handling Equipment.—The coal is entirely handled mechanically by means of grab, bucket, and conveyors. The coal is lifted from the hold of the colliers and distributed into the bunkers over the boilers, which have a capacity of 10,000 tons, or sufficient for two weeks' supply. To avoid the possibility of interruption in the coal supply, very large storage capacity has been provided. Labour questions at the mines or on the railroads, or storm blockades in transportation over the railroads, the water, or the city's streets are possible causes of interruption. To avoid these, at each step in its growth the company has made what seemed to be adequate provision for coal storage. Consequently, in 1903, a large tract of land known as Shadyside, on the New Jersey shore of the Hudson River, opposite the Grant Monument on Riverside Drive, Manhattan, was purchased and thoroughly equipped with coal-handling machinery. Coal may be delivered on the property by either boat or rail, and automatically placed in the storage piles. In the station, buckets or endless chains lift the coal to the bunkers on the upper floors, and it is delivered at the doors of the boilers by gravity. In this storage yard it is lifted on enormous trusses, and by gravity takes place on the pile, where it remains until needed for use.

Boilers.—There are 56 boilers of the water-tube type, each 18ft. long, with 6,500 square feet of heating surface, and rated at 650 h.p. As the engines require only 12·5lb. of steam per indicated horse-power, the boilers easily develop enough steam to meet all their requirements. As divided, there are 28 boilers on each floor, standing in two rows, in batteries of two each, facing an aisle 30ft. wide. They are designed for 225lb., and now operate at 176lb. pressure per square inch. There is a complete installation of blowers of large capacity for forced draught, and 20 of the boilers are provided with automatic stokers with the necessary auxiliary apparatus for their operation. The remainder, in which anthracite coal is used exclusively, are fired by hand.

Engines.—It was intended originally to instal 16 engines of the vertical marine type, three-crank, with one high and two low pressure cylinders. The development of the steam-turbine in the larger units has made it seem desirable to modify these plans somewhat, and 11 only are so far erected. The balance of the equipment will consist of turbines and their auxiliary apparatus. With 175lb. of steam pressure at the throttle, 27in. of vacuum, and 75 revolutions per minute, at the most economical load the engines indicate between 5,200 h.p. and 5,500 h.p. They are capable, however, of a sustained load of 8,000 h.p., and of an ultimate capacity at the maximum cut-off of five-eighths of the stroke of 10,000 h.p. The load or speed of any engine when running in multiple can be varied by the adjustment of the governor mechanism by an electric motor controlled from the operating gallery. Each engine has a surface condenser of the Worthington type with a cooling surface of 9,200ft.

Steam-Turbines.—Turbines of the Curtis type, manufactured by the General Electric Company, each having a capacity of 5,000 kw., are now in course of installation, and will be in service in time to assist this winter. The first turbine is of the two-stage type, with eight rows of revolving blades and six rows of guide blades, divided equally between the stages. The second and third turbines will be of the four-stage variety, having four sets of expanding nozzles and four revolving units, each unit containing two lines of blades, with one line of guide blades between them. In the first type the steam is partially expanded at the first set of nozzles, flows through the four revolving blades and three guide blades of the first wheel, and expansion is then finished in the nozzles between the stages. The steam then passes through the four revolving blades and three guide blades of the second stage into the exhaust chamber in the base of the turbine, and from there passes into the condenser, standing beside the turbine and of about the same height.

Generators.—Directly connected to the engines, the generators are of the revolving-field type. They are rated for continuous operation at 3,500 kw., and for short periods are capable of sustaining an overload which is limited only by the capacity of the engine. Three-phase current at 6,600 volts is generated at a frequency of 25 cycles per second. By test, the actual efficiency for one-quarter overload is 97·2 per cent.; full load, 97 per cent.; three-quarter, 96½ per cent.; and half-load, 95½ per cent. The regulation is such that if the full load be suddenly thrown off, the rise in the voltage of the generator will not exceed 8 per cent.

Field Excitation.—Each exciter set, of which there are three in the station and a fourth in course of installation, consists of a 225-h.p., 6,600-volt three-phase induction motor, directly connected to a 150-kw. direct-current four-pole generator giving a potential of 200 to 280 volts. A storage battery, occupying the vault on the Thirty-eighth-street side of the building, ensures absolutely continuity in the exciting current. The battery alone is capable of exciting the fields of 16 generators for one hour.

The Switchboard.—The controlling, indicating, and recording features of the electrical equipment of the station are confined to a series of galleries occupying the entire westerly end of the structure. The general switching arrangement in this station, which is typical of American modern high tension, is most elaborate and carefully planned out, the following conditions being carefully attended to: (*a*) that each switch shall be located in a fireproof chamber by itself so as to obviate any risk of fire; (*b*) to so separate all switches and high-tension cables leading thereto that if by chance a fire should occur on any part it will be impossible for it to incapacitate any other part of the plant; (*c*) that there shall be ample room to get at any part of the switching apparatus; (*d*) to arrange that in case of one piece of switchgear getting out of order that this shall not interfere with the operation of the unit with which it is connected; (*e*) that as far as possible there shall be a duplicate method of feeding from point to point.

It is obvious in dealing with plant of the size contained in a modern power station that this cannot be controlled in the old way, where all leads and connections are brought to one switchboard and operated by switches fixed thereto. In the station now being described, the high-tension switches are contained in separate brick or other incombustible chambers, and thus we have in the station four galleries, on each of which are situated rows of these brick chambers, each containing a three-phase oil-break switch. On the top of each chamber is located a small series motor which operates the oil switch, and is itself operated by a low-pressure current. The leads from all these small motors are carried back to a controlling board, on which are mounted close together and in a most compact space the small switches for operating the small currents at low potential which operate the main switch motors. By this means the control of a huge station can be brought to quite a small board, usually arranged in the form of a flat table.

The general lay-out of the arrangement for the control of each generator and cable is as follows: The main cables from each three-phase generator are brought first to a three-phase, oil-break, motor-operated switch, the cables being so arranged that they are kept perfectly separate from the cables of any other generator or feeder. This main oil-break switch is situated on the first gallery above the ground floor. From here the machine cables run to the fourth gallery, where they are connected into what is known as the selector oil-break switch. This is a similar type of switch to the main switch, but is

Digitized by Google

arranged so that the machine can be thrown by it on to either the main 'bus bars or on an auxiliary set of 'bus bars. Each feeder cable on entering the station is brought first to an oil-break switch motor, operated and also equipped with a relay, which enables the switch to be used as a circuit breaker, automatically opening the circuit at any predetermined limit of current. From this it passes straight up to a second oil-break switch similar to the first, but not arranged as an automatic breaker. The object of having two switches in series is to be able to disconnect a cable even if one of the switches becomes inoperative. From the top of the second switch the leads pass through what is known as the feeder selector switch, which enables each cable to be connected to either the main or auxiliary 'bus bar. The controlling board which operates these switch motors contains small double-throw switches. Throwing the switch in one direction closes the main oil switch and in the other direction opens same, a small red lamp showing bright when the oil switch closes and a green one being lighted up when it is opened. If for any cause the oil switch does not respond when its controlling switch is operated, the lamps indicate same to the engineer of board. Not only are the oil switches operated from this controlling board, but the governors of the engines are also operated by motors, the control of which is brought to the same board, so that the engineer in charge has the operation of the whole station under his command at this control board.

The three-phase 25-cycle current at 6,600 volts generated at the Waterside station is distributed to the various rotary converter sub-stations by underground cable feeders following four distinct trunk lines of subway ducts. The size of the cables used for feeders has been selected to secure the best utilisation of a 3in. duct, the size generally used by the Subway Company, through whose ducts much of the cable is laid. To fill these conditions the standard copper section was adopted of 250,000cm. sectional area for each of the three conductors. The company is now operating about 41 miles of rubber-insulated cables and 28 miles of paper-insulated 6,600-volt cables. The company has now in operation 16 rotary converter sub-stations on Manhattan Island. In several of these sub-stations the rotary converters are operated in connection with existing steam plants; in others rotary converters only are operated. In each of the latter, as well as in several of the former, there are one or more storage batteries, of which mention will be made later.

Of the existing generating stations, only the Duane, Twelfth, and Twenty-sixth streets stations are operated as combined steam and rotary sub-stations, their existing steam plants being utilised as generating stations supplementary to the Waterside station during the period of heavy loads in the winter months. All the other stations will finally be exclusively rotary converter sub-stations.

The Sub-Distributing Stations.—The typical equipment of a rotary converter sub-station is: (1) high-tension switchboard for high-tension feeders and rotary converter machine panels; (2) air-blast static transformer; (3) low-tension alternating-current switchboard for the operating of rotary converters; (4) rotary converter I.R.T. regulators; (5) rotary converters; (6) low-tension direct-current switchboard and 'buses with instruments and synchronisers; (7) storage battery and booster set; (8) compensating for balancing loads on three-wire system; (9) low-tension feeder panels. The course of the current through one of the sub-stations is as follows: Coming into the station on the high-tension three-conductor cable feeder as three-phase, 6,600-volt, 25-cycle alternating current, it passes through the high-tension feeder panels. From the high-tension machine panels connections are made by duplex cables to the high-tension primaries of the static transformers; the secondaries are connected through alternating-current switches to an I.R.T. regulator and then to the alternating-current collector rings of the rotary converter. The direct-current terminals of the rotary converter are wired to the positive and negative switches of the machine, which can be connected to three sets of 'bus bars supplying current to the low-tension direct-current feeders. The rotary converters are all built for a normal potential of 270 volts, which can be raised or lowered 30 volts by the I.R.T. regulators, and the unbalancing of the station load between the two sides of the system is taken care of by the storage battery and a compensator.

The reason for the employment of three sets of 'bus bars is because the company have only one standard size of low-tension feeder cable, which is of an area of 1,000,000cm., as the length of these cables between the sub-stations' 'bus bars and the point at which they feed the network vary considerably. If they were all supplied at the same electrical pressure the short feeders would be overloaded, and the ones feeding to a distance would supply the network there at a low pressure. Consequently, in each sub-station there are three sets of 'bus bars, each set at a slightly higher potential than the one below, and the cables can be connected as required to either of the three sets of 'bus bars according to the load which it has to carry. The different voltages of these three sets of 'bus bars are also useful for the charging and discharging of the accumulators, the arrangement at peak load usually being that the accumulators are discharging through the lowest pressure set of bars which feed the shortest feeders. The bulk of the generating machines are connected to the middle set of 'bus bars, a few machines being connected to the higher set of 'bus bars, to which are connected the extra long feeders. On a large system like this the arrangement of having only one size of low-pressure and one set of high-pressure feeder cables illustrates well the length to which American organisation will go in order to have standardisation and simplicity wherever possible.

Static Transformers.—The static transformers are all of the air-blast type, and are in sets of three 200-kw. and three 400-kw. respectively for 500-kw. and 1,000-kw. rotary converters. They are mounted on a platform constituting the air-duct for ventilation under an air pressure of ½oz. to ¾oz. supplied by electric blowers installed at one or both ends of the platform. The primary and secondary transformers are wound for a ratio of transformation of 6,300 to 170 volts, but other ratios may be obtained by connecting to intermediate taps to compensate for drop on feeders of different lengths and to facilitate adjustment of alternating-current voltage to direct-current voltage required. In the later transformers a thermometer is mounted in a casing between transformer coils to give temperature indications.

I.R.T. Regulators.—The secondaries of the induction regulators are connected in series between the electrically-operated switches and the alternating-current collector rings of the rotary. The potential or primary windings of the regulators are connected across the secondaries. The primary windings are wound on the rotor of the regulator, which can be turned through a fixed angle in either direction by a small direct-current motor or induction motor controlled from the operating switchboard. The I.R.T. regulators of General Electric and Westinghouse make have 65 kw. capacity for 500-kw. rotaries and 130 kw. capacity for the 1,000-kw. rotaries.

Rotaries.—The rotaries are six-phase and of two sizes, 1,000 kw. and 500 kw. rated capacity. The 1,000-kw. rotaries are 270-volt direct current, 187½ revolutions per minute; the 500-kw. rotaries are either six-phase 270-volt direct-current, 375 revolutions per minute, or six-phase 300-volt direct-current, 375 revolutions per minute. The latter type are equipped with 130-kw. I.R.T. regulators, by means of which the rotary can be operated between the range of 240 to 360 volts direct current, the higher voltage being required in the up-town sub-stations owing to the length of low-tension feeders. The overload capacity of the rotaries is liberal; they are designed to carry 25 per cent. overload for three hours after carrying continuously full rated load, or 50 per cent. overload for one hour. The efficiency of the rotary converters is high. In the case of 1,000-kw. converters an efficiency of 96 per cent. and in the 500-kw. 95¾ per cent. has been obtained. The rotary converters were supplied by the General Electric Company and the Westinghouse Company.

Storage Batteries, Boosters, and Compensators.—Storage batteries are installed at nearly all the stations from which current is distributed, and they perform at least three important functions: (1) they ensure continuity of the service; (2) they smooth out the irregularities of the local demand; (3) they assist in the regulation of the system. The standard battery used contains 150 cells, 75 between the neutral and each outside wire. Each cell has a capacity of 2,000 ampere-hours at a one-hour rate, 3,000 ampere-hours at a three-hour rate, 4,000 ampere-hours at a 10-hour rate.

Low-Tension Feeders and Mains.—The feeders and mains are all underground, and are connected in a continuous network on the Edison three-wire system, 2×120 volts at the customers service. For feeders the company has adopted a lead-covered, paper-insulated, two-conductor, concentric cable, with a copper section of 1,000,000cm. for each conductor, and provided with six pressure wires. The common neutral system is used as a general neutral serving for all feeders, and connecting with a neutral main at every block.

Currents Generated.—For all the company's generating stations the maximum load on Manhattan Island during 1903 was 359,460 amperes, which at the average station pressure of 140 volts equalled 50,600 kw. It is expected that the Manhattan Island maximum of 1904 will approximate 425,000 amperes at 140 volts. The output of the generating stations on Manhattan Island during 1903 aggregated 131,000,000 kilowatt-hours. The ratio of maximum load to connected installation was 36·6 per cent., a percentage which has been decreasing from year to year with increased concentration in the generation of current and greater diversity in the purposes for which it has been employed. The average load on the Waterside station for the maximum day of 1903 (Dec. 24) was 21,535 kw., a load factor of 56 per cent. of the 24-hour capacity; the average for the month of December was 18,059 kw., 47 per cent. of the capacity.

Installations Supplied.—Current is supplied through more than 42,000 meters to installations aggregating 1,507,342 incandescent lamps, 19,386 arc lamps, 85,072 h.p. in motors, and 2,000 kw. in customers' storage batteries, heating, and cooking

Digitized by Google

appliances and experimental apparatus. Of the arc lamps, 3,126 are supplied for the municipality. The aggregate of these installations is the equivalent of 2,955,214 lamps of 16 candles, each averaging 50 watts.

Prices.—Current is sold to the public under several schedules, the one selected in each instance being that which offers to the customer the best arrangement that can be made. The price varies only between given classes. One cannot obtain a price better than another's in the class, and to get in any class it is only necessary to comply with the conditions that control it, which are alike to all. To the smaller customers current is sold under a retail contract, in which the maximum price is 15 cents a kilowatt-hour, falling as the average use of the installation increases; thus it is 10 cents for the third and fourth hours of average use, 7½ cents for the fifth and sixth hours, and five cents a kilowatt-hour for all use in excess of six hours daily. The larger installations are supplied under wholesale contracts, which, through the medium of guarantees, ensuring a relatively large consumption of current, offer marked reductions from the prices of the retail schedule. Thus, on what is known as the wholesale "A" form, a customer guarantees a monthly use of current amounting to 2,000 kilowatt-hours, and a daily average use of the installation of two hours, for 10 months of the year, and the maximum price is reduced to 10 cents a kilowatt-hour. For all current in excess of four hours' daily average use of the installation, the price is reduced to five cents a kilowatt-hour. There is also a second wholesale form of contract, which deals with customers taking a still larger quantity of power; and there is a third form of wholesale contract, which was developed in order to get on to the supply mains, many of the huge blocks and buildings which have hitherto been supplied with current by their own private lighting plant. This schedule is for customers taking supplies of from 10,000 units per month for 12 months in the year, when the maximum charge is five cents per unit, which is reduced to three cents per unit for current in excess of 50,000 units per month per year. For these wholesale contracts the consumer has to supply space free for the installation of a high-tension sub-station by the company.

Incandescent Lamps.—Experience has shown that where customers who are not informed technically purchase incandescent lamps upon the open market their standards of lighting diminish materially, causing not only dissatisfaction to the immediate user, but a very poor opinion generally on the part of prospective users. For this reason the company requires that all retail customers shall permit it to supply incandescent lamps, including them within the price for current. The wholesale customers in the private plant class, however, have the option of purchasing incandescent lamps either from the company or elsewhere, and when this option is exercised a special reduction of one cent per kilowatt-hour is made.

Metropolitan Street Railway of New York.

As is well known, the electric tramways in the Manhattan Island, New York, are operated on the conduit system, although there are still to be seen in New York a number of short lines operated by horses, the expense of constructing the conduit not being warranted by the traffic on these lines. The company work electrically the equivalent of 200 miles of single track, and to produce the necessary power for operating the 2,000 cars on the daily schedule (over 3,000 cars are owned by the company) there are two power stations, one known as the Ninety-sixth-street and the other as Two hundred and eighteenth-street stations. The Ninety-sixth-street station contains 11 6,600-volt 3,500-kw. three-phase 25-cycle generators. These generators are driven by vertical cross-compound condensing engines. Steam is furnished to the engines by 80 boilers, nominally rated at 250 h.p. each. The output has been in times of heaviest load (which occurs about Christmas) as high as 575,000 kilowatt-hours per day. The output during the maximum hours of the day has frequently gone as high as 36,000 kw., or about the nominal load for the 11 generating units. The coal consumption at this power station is stated to be about 2·8lb. of coal per kilowatt-hour, and the total output of the station for the year ending Dec. 31 last was 149 million units. The Kingsbridge or Two hundred and eighteenth-street power station supplies current to the two northern sub-stations on Manhattan Island, to the borough of the Bronx, and to the sub-station at Mount Vernon and Yonkers. The arrangement at this station follows the same general plan as the Ninety-sixth-street power station, the generating unit being eight in number and of the same size as those just described. This station is not at present and never has been fully loaded. The three-phase current is distributed to rotary converter sub-stations located throughout the city, the general arrangements with regard to switchboard distribution and sub-station equipment being practically of the standard type as already described in the Edison station.

Electrical Equipment of the Inter-Borough Rapid Transit Company.

Manhattan Island Railway Division.—The Inter-Borough Rapid Transit Company have leased all the elevated railways now in operation in Manhattan Island and in the borough of the Bronx. The rolling-stock required is over 1,500 cars, and during the hours of heavy traffic 1,332 of these cars are in service on the road. About 85,000 passengers are carried each day, the heaviest passenger load on record being 1,063,000 passengers carried on April 4 this year. The trains were formerly operated by steam locomotives, but are now worked by electric cars on the General Electric Sprague system of multiple-unit control. The power station for operating this system is equipped with eight Allis-Chalmers engines, each of 8,000 h.p., and which are each directly connected to a 5,000-kw., three-phase, 11,000-volt, 25-cycle generator, but the alternators, and also the engines, are designed to carry an overload of 50 per cent. for two hours, and in service they are frequently loaded up to this amount for short spaces of time. The eight alternators have delivered to the line from 40,000 kw. to 47,000 kw., and, at the same time, an additional 500 kw. to 6,000 kw. was being supplied by the Kingsbridge station of the Street Railway Company. In order to meet the increased demand for power, a 5,500-kw. alternator, driven by a Parsons steam-turbine, is soon to be installed. The 11,000-volt alternating current is transmitted to seven rotary converter sub-stations, the general arrangements being similar to those already described, with the exception that the high-tension gear is designed to deal with 11,000 volts current. The General Electric form H oil switch is used throughout, and it is stated that, under most severe conditions in service, it has opened the 11,000-volt circuits without trouble of any kind.

Subway Division.—As well as operating the elevated railways of Manhattan, the Inter-Borough Company has just constructed at huge expense a subway totalling a length of about 20 miles, or equivalent to 63 miles of single track, of which a small portion at either end is elevated. On part of the route there are four tracks, so as to enable the operation of express and local services. This subway is in no way a deep-level tube, as in London, but is immediately under the surface of the road. The service is just now opened, and when thoroughly organised it is estimated that the combined express and local services will require 700 cars, and the power required when the maximum number of trains are on the line is estimated to be 52,300 kw. The power station is located on the North River, between Fifty-eighth and Fifty-ninth streets. It is designed to contain 11 5,000-kw. engine-driven alternators, which will furnish power for the subway cars, and four 2,500-kw. turbine-driven alternators for the supply of light in the subway. The station differs from all other large power stations in New York in the arrangement of the boilers, which are all on one floor, placed in two rows, with centre fire aisle. Six brick stacks will eventually be erected, although at the present time only four are built. The stacks are 15ft. inside diameter and 225ft. above the grates. The nine Allis-Chalmers engines ordered are of the same type as those in the Manhattan elevated train section, consisting of two horizontal high-pressure cylinders, each 42in. in diameter, and two vertical low-pressure cylinders, each of 86in. diameter. Each engine is rated at 7,500 i.h.p., and when operating at best efficiency the guaranteed steam consumption is 12·25lb. of dry steam per indicated horse-power. The 11,000-volt three-phase alternator is mounted on the main shaft, between the main bearings of which there are only two, as the high and low pressure connecting rod on each side are connected to the same crankpin. Fuel economisers will be installed, and most of the boilers are hand fired. The alternators are of the Westinghouse make, and rated at 5,000 kw. The armature windings differ in design from those of the Manhattan engines, the conductors being formed in U-shape coils, which are slipped through the partially closed slots from both sides of the armature; the ends of the U-shaped conductors are bent and soldered together, forming closed coils, the ends of which are connected to other similar coils. There are eight sub-stations located—four on the main line and two on each branch—at an average distance apart of 12,000ft. Foundations are provided for eight 1,500-kw. rotary converters in each station, and the transformers are air cooled by forced draught.

(To be continued.)

Brisbane.—Tenders are invited by the Deputy Postmaster-General for the supply and delivery at the Telegraph Office Yard, Thursday Island, of 100 tubular wrought-iron telegraph poles to Specification No. 11 and Schedule No. 51, and also for the supply and delivery at the cable tanks, Thursday Island, of three nauts of submarine cable to Commonwealth Specification No. 8 (Queensland, No. 22) and Schedule No. 50. Tenders by Dec. 12. They must state the time required for delivery; this time will be counted from the date of the notification of the acceptance of the tender. Specifications and forms of tender can be obtained at the General Post Offices, Sydney, Melbourne, Brisbane, and Adelaide. Neither the lowest nor any tender will necessarily be accepted. Tenderers are required to note that Customs' duties must be included in all charges, as per clause 2 of the general conditions. All tenders sent by post must be registered.

NOTES.

The Institution.—At last week's meeting the President stated that he thought the proceedings of the Institution should terminate, as nearly as possible, by 9.30, in justice to the staff of the Institution of Civil Engineers.

The McMillan Fund.—We are pleased to learn that, owing in a large measure to Mr. W. H. Patchell's vigorous appeal at the Institution dinner, this fund has now realised the £2,000 which the committee always hoped to attain. This generous response of the members on behalf of the late secretary's family is a matter for congratulation.

Right of Way.—The Supreme Court of the United States has decided in favour of the Pennsylvania Railroad, a case involving the right of that company to remove poles belonging to the Western Union Telegraph Company from its right of way. The court held that the Congressional Act of 1886 does not grant an "eminent domain" to telegraph companies over the private property of railroad companies.

Scientific Education.—The new science buildings connected with King's School, Grantham, which have been erected at a cost of £16,000, were opened last week by Sir Oliver Lodge, principal of the Birmingham University. Sir Oliver, in his address, said he would like to see the control of education more localised, as he considered that the Board of Education was overburdened. Scientific education had great possibilities, but to some extent was on its trial, and it rested with the boys of to-day to establish it.

Wireless Telegraphy.—In order to obtain better results, and to foster the wireless telegraphic industry in that country, the firm of Siemens and Halske in Russia is developing the Popoff system in conjunction with the Gesellschaft Drahtlose Telegraphie. It is anticipated that the experience gained with the various systems in Germany will enable the undertakers to bring the Russian system up to the modern standard. It is reported that the wireless telegraphy station at Bari (Italy) has received 400 words from Poldhu (Cornwall) in half an hour. The experiments are being continued with very satisfactory results.

What is a Workman?—This oft-asked question was submitted to the Bournemouth magistrates on Wednesday, when a journeyman butcher was charged with using a workman's ticket in contravention of the local tramway by-laws. The bench held that the defendant was not a "workman," and imposed a small penalty. The usual definition of a "workman" is one engaged in manual labour, but this interpretation is not rigidly adhered to at all places. In some cases a part of a man's duties are of a manual character, which rather complicates matters. Would not the simplest solution of the controversy about ill-remunerated clerks being charged full fare, while well-paid foremen have the benefit of the reduced rate, be to make cheap travelling the reward of early rising irrespective of occupation? This is the practice on the Central London Railway, where prince or peasant can have the advantage of the cheap rate by using the early morning trains.

Personal.—Our sincerest sympathy is with Mr. C. J. Sutherland, who, on the ground of ill-health, has just resigned his position of electrical engineer to the Worcester City Council. At the meeting of the Council last week the members were unanimous in their expressions of regret, and some enthusiastic tributes were paid to the admirable manner in which Mr. Sutherland had performed his duties. The chairman of the Electricity Committee said that he had always acted fearlessly and faithfully, and the advice he had given to the Council was of the soundest. Alderman Millington said that Mr. Sutherland was one of the best officials he had ever come into contact with. We echo the chairman's regret that the resignation should be due to such a cause, but trust that the complete abstinence from work which has been ordered by his medical adviser, and perhaps a change of climate, will result in Mr. Sutherland enjoying many years of well-earned relaxation. It is gratifying to hear that the last few days have witnessed an improvement in his health.

Another Tramway Association.—There are already in existence three associations in connection with tramways and light railways, and the general consensus of opinion seemed to be that the number should be reduced rather than enlarged. A fourth has, however, recently made its appearance, but its *raison d'être* is explained by the fact that its operations will relate solely to the affairs of the Metropolis and its environs. The Metropolitan Association of Electric Tramway Managers, as the new institution is designated, was decided upon at a meeting of tramway managers held at the Municipal and County Club. The membership area will cover the county of London, Croydon, Bexley, Erith, West Ham, East Ham, Ilford, Barking, Leyton, Walthamstow, South Middlesex, and other districts in close proximity to London where electric tramways are being developed, either by municipalities or companies. Mr. A. L. C. Fell, chief officer of the London County Council tramways, was elected chairman, and Mr. H. E. Blain, tramways manager, West Ham Corporation, hon. secretary.

The Pacific Cable Conference.—It is announced that the Pacific Cable Conference, which was to have met at the Colonial Office last month, has been postponed owing to the fact that the Canadian Postmaster-General is unable to be in England at present on account of the elections and other matters. So far the Canadian Government has not indicated a date on which the Dominion delegate will be able to come to London, but the Pacific Cable Board, as well as the delegates to the conference, are anxious for the conference to meet as soon as possible, and it is hoped that it will assemble at an early date. The delegates to the conference appointed by the contributing governments are: the Secretary of State for the Colonies, president; Sir William Mulock, Canada; Sir Sandford Fleming, New Zealand; and Lord Jersey, the Australian Commonwealth. Sir Sandford Fleming, who is in Canada, has been collecting information for presentation at the conference. Lord Massy has joined the Pacific Board as one of the representatives for Australia, in succession to Sir Horace Tozer, who has resigned his post owing to his return to Queensland.

Speed Limits.—From time to time the anomaly in regard to the speed limits for trams and motorcars respectively has been the subject of comment, and now the Tramways and Light Railways Association have made cogent representations to the Board of Trade. It is scarcely apparent why trams running on a well-defined track, and for the public convenience, should be restricted to an average of something like eight miles an hour, while owners of motorcars may in general career along at between double and treble that pace. This disparity, however, is due rather to the ultra-cautious policy which places such limits upon the speed of trams than to excessive latitude in the case of the motorist, because, as the association point out, a higher speed is now practicable for road traffic, with due regard to the public safety, than was formerly considered desirable. The association submit that the Board should, therefore, adopt a standard uniform with that of the motorcar, and sanction a general limit of 20 miles an hour, reservations being made for special cases. This is certainly a pretty big jump, and may savour somewhat of the hustling

Digitized by Google

tactics of New York. If, however, this be considered too radical a change, tentative increases of, say, 20 per cent. in urban and something up to 50 per cent. in rural districts might be tried.

Birmingham Electric Club.—A large number of members assembled at the first meeting of this new institution on Saturday night at the Colonnade Hotel, Mr. J. J. Inniss presiding. In his inaugural address Mr. Inniss pointed to the great possibilities of the club, and said it was essential that the standard of the aspirations of the members should be raised as high as possible, having regard to the advance, educationally, which has taken place during recent years in Birmingham. As the club membership included all departments of the electrical profession, he hoped that the papers to be read at the meetings would be as practicable as possible. Like other professions, that of the electrical engineer was somewhat crowded in some of its departments, but there were satisfactory openings for good men, such as designers of machines, as at present some of the large firms had to go abroad for their chief designers. There were also great possibilities in other directions, and in support of this he reviewed the advance that has taken place during the past decade in the various branches of the electrical industry. We are happy to see that this new organisation has been launched under such favourable auspices, but we sincerely trust that it will refrain from duplicating the work of the Birmingham Section of the Institution of Electrical Engineers, and devote itself rather to the social side, in which sphere it should have a distinct future.

The Dolter Surface-Contact System.—We note that a trial has been given to the Dolter surface-contact system in Dresden, over a section of track between 300 and 400 yards long. An old accumulator car was converted for the purposes of the experiment, and it is an interesting fact that this car has a wheel base of only 1·75m., despite which no difficulty was found in mounting the electromagnets used to actuate the contact studs. There is a short break in the continuity of the current supply as the car is approaching or leaving the section, during which a 12-volt osmium lamp serves for illumination at night, being run off the accumulators installed as a reserve for energising the electromagnets. Since the trials, extending over some four months, have been satisfactory, the authorities are retaining the system, and have granted a concession for the regular service of the converted car between Blasewitz and Tolkewitz It has also been decided to adopt the Dolter system on some of the routes at present served by accumulator cars. Thus Dresden, which long boasted of three distinct systems of electric traction, has now added a fourth, the overhead trolley, conduit, accumulator, and surface-contact systems being all represented on a practical scale within its borders.

Tramway Electrical Equipment.—The *Official Circular* of the Tramways and Light Railways Association contains the model description issued by the Board of Trade for the electrical equipment of tramways or light railways on the overhead trolley system: "Power will be supplied at from 500 to 550 volts through underground feeders to hard-drawn trolley wires —— S.W.G. The feeders will be lead covered, laid in troughing, filled in solid with composition, and covered with hard-burned tiles or other suitable protection, or will be drawn into earthenware ducts. Swivel trolley heads will be used, and the trolley wire will be in general at a height of about 21ft., and at a distance horizontally of from 4ft. to 5ft. from the centre of the track. The trolley wires will be flexibly suspended from brackets fixed to tubular poles, or in some cases from span wires fastened to poles or to the walls of houses by suitable means, and in such a way as to provide for double insulation throughout between the trolley wires and earth. The bracket arms will have an average length of — ft., and will in no case exceed — ft. in length. Section switches will be provided at every half-mile, either in pillar boxes, or in boxes attached to the poles or to houses. Feeder switches will be provided in pillar boxes, and all pillar boxes will be arranged to prevent explosion of gas accumulating in them, or in ducts connected with them." The Board of Trade have also issued a plan on a scale of 6in. to one mile giving a typical diagram of the feeders, feeding points, return feeders, earth-plates, and pilot wire points.

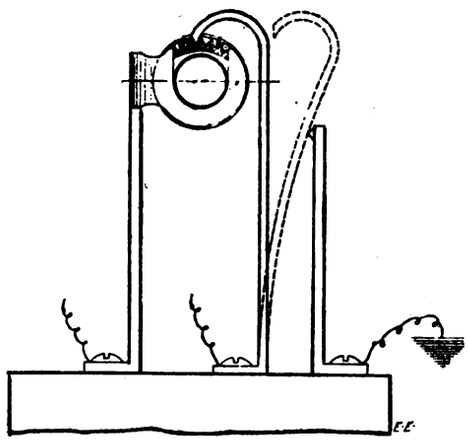
The Electrical Engineers (R.E.).—The annual dinner of the non-commissioned officers' mess was held at Anderton's Hotel on Saturday, C.S.M. Marshall in the chair. An excellent attendance, including several officers, assembled, very few vacant chairs being noticeable. There were some half a dozen toasts, and a number of capital speeches were made. C.S.M. Marshall, in giving "The Officers," alluded to their admirable technical qualifications, which included the ability to run a dynamo and still keep the belting on! Captains Rosenthal and O'Shaughnessy replied, the latter paying a warm tribute to the N.C.O.'s as "the backbone" of the force. Q.M.S. Applebee gave "The Permanent Staff," which was responded to by the adjutant (Captain Dumble), C.S.M. Wiltshire (who is leaving the corps amid mutual regrets after completing his term of service), Sergeant Riley, and Sergeant Bufton (who expressly disclaimed the gift of oratory). The toast of "The Visitors" was responded to by Q.M.S. Logley (R.G.A.), Sergeant Sheer (of the 1st Middlesex R.E.), and Mr. Tucker. Lieutenant Shepherd proposed "The N.C.O.'s Mess," and expressed the belief that the new system of company formation would prove a great advantage, Sergeant Matthews and others responding. Finally, Sergeant Bird gave "The Press," and doubtless said some very agreeable things, but the mirth prevented all his remarks from being audible at the Press table. C.S.M. Marshall was a most genial chairman and ready spokesman, and mention should not be omitted of the several entertainers, some of whom were exceedingly humorous.

The New York Subway.—Despite the objections raised by some physicians to the hygienic conditions of the New York Underground, the service appears to have given pretty general satisfaction, and some influential members of the medical profession have voluntarily undertaken the task of rebutting the views of their professional brethren. The feature that appeals most strongly to the down-town business man and the theatre-goer is the system of express trains, in which the operating company has fully redeemed its promise of a 15 minutes' service to Harlem. These trains have hitherto been run under a four-minute headway, but now that the east side branch of the road has been opened, the expresses will be run under a two-minute headway as far as the junction at Ninety-sixth-street, and a four-minute headway upon the two branches of the road from that point to their respective termini. There are two features in particular that mark the road as constructed on the most up-to-date practice in electrical traction. One is the remarkably rapid acceleration, which amounts to 1·25 miles per second, and the other is the splendid condition of the track. The combination of 100lb. rails with a tie-plate on every tie, and broken stone ballast laid on a concrete foundation, provides a remarkably smooth track, in which both surface and alignment are all that could be asked. Another feature that contributes to comfortable riding is that the curves are "spiraled"—that is to say, the track runs from the tangent to the maximum curvature in a parabola, the change of direction being so gradual that the

Digitized by Google

jolt which usually accompanies the entrance of a train upon a curve is entirely removed. The express train service is regarded as the great feature of the new undertaking, and it is understood that the company intend to extend this class of traffic.

New Cut-Out Design.—An addition has been made by Mr. F. B. Cook, of Chicago, to the forms of cut-outs designed to effect the self-repairing of the heat coils, of which a description appears in the *Electrical World* of New York. The arrangement of parts is shown in the accompanying diagram. The thermal device is cylindrical, the



surface being serrated. The cylindrical piece can revolve between cheeks which bear upon its ends, except when it is held fast by cement or solder inserted in these joints. One side of the circuit to be protected is carried to the holder, while the other is connected to a spring piece, which may be hooked over one of the teeth of the cylinders, as shown. Upon the passage of an excessive current the thermal device softens the current, and the pull of the spring piece rotates the cylinder and becomes released and flies back out of contact, opening the circuit. As the cylinder cools the cement hardens, leaving everything in readiness for resetting.

Railway Electrification.—The electrification of the Springs-Randfontein section of the Central South African Railways has been contemplated for some time, and we learn that the authorities have now, in consultation with Messrs. Mordey and Dawbarn, evolved a definite scheme for the accomplishment of this work. The Government, through its London agents, has entered into a provisional agreement for the conversion of the line with an English-American firm, and the details of the scheme have been communicated to the members of the Inter-Colonial Council. Messrs. Mordey and Dawbarn estimate that by electrification of the Springs-Randfontein line a saving of fully £40,000 per annum will be effected. This amount has been arrived at without allowing for increased revenue due to an improved service. Allowing for this improvement, the direct saving, it is estimated, will amount to £60,000 per annum. This increased saving is arrived at on the basis of a 20 per cent. increase in the train mileage, and a 29 per cent. reduction in the time occupied by each journey. The price mentioned is £445,000, the estimate of Messrs. Mordey and Dawbarn amounting to £430,000. It is stated that hitherto the administrators have only been deterred by the difficulty of raising the capital, but it is understood that the contracting firm are prepared to accept payment out of the profits of the line at the rate of £25,000 per half-year, commencing two years from the placing of the order, with interest at the rate of 4 per cent. on deferred payments. Lord Milner views the scheme with favour. If the results turn out as favourably as is expected, the electrification of other sections is pretty sure to follow; the railway authorities have themselves indicated as much. Although the firm with whom the provisional arrangement has been made is an English-American one, we are glad to see that British plant only is to be utilised, so that the scheme should result in many big orders for British houses.

The Nobel Awards.—It is gratifying to see that England has gained a double success in the department of scientific research, two of our most prominent physicists in Lord Rayleigh and Sir William Ramsay having gained the Nobel prizes for physics and chemistry respectively. To describe the careers of these distinguished scientists would be a superfluous undertaking, as our readers are doubtless familiar with them, but a few remarks in regard to same may be of interest. Lord Rayleigh was senior wrangler in 1865, since when, by experimental and mathematical research, he has been a constant contributor to scientific progress. He is one of the greatest living authorities on acoustics, his "Theory of Sound" being a standard work. His best known and perhaps most valuable discovery was the finding of argon in the atmosphere just a decade ago. By a most refined chemical investigation, in the later stages of which he was associated with the other Nobel prize-winner, Sir W. Ramsay, he demonstrated the existence of an inert gas, which was added to the list of elements under the name of argon. It is announced that his lordship will present the value of the Nobel prize (about £7,825) to his Alma Mater. Sir William Ramsay has been the recipient of almost every medal and honour conferred by scientific bodies. Educated at Glasgow and Tübingen, Sir William became successively principal of University College, Bristol, and professor of chemistry at University College, London. He followed up the discovery of argon first by the detection of helium in the mineral clevite, and then his skilful investigations, assisted by Dr. Travers, resulted in the detection of three new gases in our atmosphere—krypton, neon, and xénon—the experimental work leading to these results ranking with the most refined ever carried out. Of xenon, for example, there is about one part in 70,000,000 of air. Recently Sir William and Mr. Soddy have demonstrated that the ultimate residue of the disintegration of radium is helium.

Damages for Tramway Accident.—The payment of £1,000 as damages for an accident would be a pretty hard hit to a young and struggling undertaking, so it is rather fortunate that the Corporation which has been mulcted in this sum is one of the most prosperous in the kingdom. At the same time, the authorities at Liverpool are to be commiserated with upon the display of muscular energy by one of their servants which resulted in this liability being incurred. The plaintiff was an elderly medical man who was travelling on the Corporation tramways, and he entered the interior of the car with a lighted cigar. He did not attempt to smoke it, but declined to extinguish it. Thereupon the conductor ejected him from the car, with the result that he sustained a broken leg. The judge stated that he did not feel any sympathy for the plaintiff, who had acted very stupidly, but at the same time his lordship awarded him a very substantial solatium, on the ground that the conductor was not justified in employing "unnecessary violence." Precisely where the line is to be drawn it would be interesting to know. From the report the conductor does not seem to have acted with any deliberate barbarity. It chanced, however, that he was a very powerful man, while the passenger was an elderly and somewhat feeble one. If a conductor is not to be allowed to use force to remove a passenger who persists in infringing a by-law of this kind, it facilitates such breaches, especially in rural districts, where the local constable is not always available.

Digitized by Google

If, on the other hand, the conductor uses "unnecessary violence," it is a hardship that the owners should have to bear the consequences. But this, we fear, is an inevitable case of the principal being responsible for the acts of his agents. In certain cases the captain of a ship incurs individual liability, but even there the payment usually devolves upon the owners in practice, as default would probably gain the service a bad reputation. The position of tramway owners in these matters is scarcely an enviable one, but, happily, such incidents are relatively infrequent.

The Paris Automobile Exhibition.—On Friday last the great motor exhibition at the Grand Palais in the Champs Elysées was opened by President Loubet. The exhibition is of a representative character, but there are no striking innovations. The exhibition practically marks the disappearance of the tubular frame, the unenclosed type of radiator, and the atmospheric inlet valve. Even Renault and the De Dion firm have come substantially into line in this respect. Panhard still retains the wood and flitch plate frame, and C.G.V. the square section wood-filled tube, but with these exceptions, every French maker has adopted the "chassis embouti," first introduced by the makers of the Mercédès. The conservative Panhard, however, still adheres to the atmospheric inlet valve on the 7-h.p. and 10-h.p. cars, and De Dion retains it on all models, but everywhere else the mechanically operated valve reigns supreme. Radiators are invariably enclosed, and generally cooled by one, or sometimes two fans. There is a distinct tendency to place the fan in the flywheel, and where the belt-driven fan is retained, provision is generally made by means of a spring for keeping the belt at a constant tension. Clutches are of many varieties, as heretofore, but the well-tried leather-covered cone type seems at least to be holding its own in popularity. The high-tension and low-tension systems of magnets are both increasing in favour, to the almost entire extinction of the old coil and accumulator method of ignition. In one or two cases the ignition-lever has entirely disappeared. There is a slight tendency to place less reliance on the engine governor, and in many cases the depression of the clutch pedal throttles the motor; and in all the Mors cars the governor has been abolished altogether, thus following the established Wolseley practice. The methods of lubrication and filling petrol tanks show considerable improvement. Prominent among the British exhibits is that of the Hozier Engineering Company, which includes a 10-12-h.p. two-cylinder car, fitted with an Astor engine built into a long frame. This car is an improved successor of that which the company successfully introduced last season.

Submarine Navigation.—One of the attractions in last week's programme at the Northampton Institute consisted of a demonstration of Middleton's system of submarine navigation. The salient peculiarity of this system is that the vessels are propelled, impelled, directed, controlled, and governed by fins actuated by prime movers—*i.e.*, engines or motors—in such fashion that they can move in any way in the fluid in which they are immersed. To simplify the motion of the fins, one or more screw propellers are, in addition, fitted to these vessels. This is, however, purely to simplify the mechanism impressing the proper motion on the fins. The fins are a new instrument of impulsion invented for the purpose of enabling a vessel to be navigated in tridimensional space, for the screw is only fitted for motion in two dimensions, and a submarine vessel should be capable of moving even better in a vertical plane than a horizontal one. Another great feature claimed by the inventor is greater safety as compared with the "A 1" type, the fins being arranged so as to promote buoyancy. A safety chamber or detachable department is provided in which the crew can leave the vessel as a last resort should it sink or founder. Dr. Walmsley is impressed by the importance of such vessels in the event of a naval war. With submersible cargo-carrying boats our food supplies could be transported with comparative safety The chief advantages claimed for the Middleton system are thus summed up: (1) the vessels of this system are completely navigable under water, being impelled and controlled by engine power, and can move in any direction in such medium; (2) the vessels of this system are nearly crewless, three men being sufficient in a vessel of 180 tons to navigate the vessel, load and fire its guns, and discharge its torpedos; (3) the vessels of this system carry guns which can be loaded and fired either above or beneath the surface of the sea; (4) the vessels of this system have a safety chamber or detachable compartment into which the crew can enter up to a few moments before the vessel is entirely filled with water, and by which they can escape from a sunk ship; (5) the vessels of this system can be made of any size. The experiments last Saturday did not proceed very far and had to be abandoned, possibly owing to the limited time for preparation. It will be of interest to observe the capabilities of the system under suitable conditions.

Electricity in Factories.—The Electrical Trades Section of the London Chamber of Commerce have forwarded objections to the Home Office with the object of securing a *locus standi* at the enquiry which is to be held into the regulations which that department has formulated under the Factory and Workshop Act of 1901. It is pointed out that difficulties may arise from the existence of two sets of rules, and the section submit that the Home Office regulations should be on identical lines with the proposed amended Board of Trade regulations. They further submit that the testing departments of electrical manufactories should be exempted from the scope of the regulations. Specific suggestions are made as follows:—"Clause 1: That alternative systems should be allowed in view of the advantages in certain cases of employing cables run on insulators and the adoption of other approved methods. Clause 5: That main distributing boards which are in charge of a special attendant should be exempted from the regulations with regard to the enclosing of switches. The section submit that the requirement as to the earthing of lampholders would be troublesome, and suggest as an alternative that an approved type of lampholder should be permitted. Clause 6: That as electrical 'undertakers' are already under penalties prescribed in various sections of the Board of Trade regulations—to see that their work on consumers premises is efficiently carried out—the section submits that it is unfair to put the onus of giving annual certificates as proposed, on such undertakers." These regulations are designed "in respect of the use and distribution of electricity where the normal pressure is greater than 250 volts and less than 650 between any two conductors." One of the reasons for the Home Office regulations is that the jurisdiction of the Board of Trade only extends to installations fed from public supply systems. A reasonable degree of legislation would probably not meet with any great opposition from manufacturers and contractors, as it furnishes the public with some assurance of the safety of electrical installations, but differences in the Home Office and Board of Trade codes are calculated to cause considerable inconvenience and expense. The differences may not be grave, though a few of the Home Office regulations appear to be somewhat obscure, but the aim of two public departments ought surely to be, as far as possible, uniformity of practice.

Pollak-Virag High-Speed Telegraphy.—At the Carlton Hotel on Friday last a demonstration was given of the high-speed telegraph system invented by two Hungarian electricians, Messrs. Antal Pollak and Jozsef Virag. This apparatus uses two line wires and an earth return, and does not involve the maintenance of synchronism between the receiver and transmitter. The message is transmitted by means of a perforated paper strip, which is punched with two sets of perforations by means of a machine with a keyboard like that of a typewriter. This strip is passed over a roller made up of six electrically-insulated sections, and metal brushes pressing on the roller form electrical connection with one or other of these sections whenever a perforation comes opposite them. The currents thus allowed to pass vary in intensity, and those from one group of three sections go to one telephone at the receiving end while those from the other group of three go to a second telephone. To the diaphragms of these two telephones, which are placed close together, a mirror is connected, and is so suspended that it is free to move both horizontally and vertically, in unison with the movements of the diaphragms. The perforations which energise one telephone are arranged to represent the vertical motion necessary in writing a character or figure, while the other set of perforations similarly represents the horizontal component. Hence the two telephones together reproduce these components, and the result is that under their combined influence the mirror moves in such a way that its motion marks out the complete characters. These motions are imperceptible directly, but if a pencil of light be allowed to fall on the mirror, the movement of the reflected ray, of course, increases in amplitude as the surface upon which it is received is removed further and further from the mirror, so that the characters described by it may be obtained of indefinite size. At the point where the size is as required, the reflected ray is made to impinge on a photographically sensitive strip of paper, and so gives a permanent record of its movements. The inventors realised that if the apparatus was to be of practical utility means must be found for the rapid development and fixing of the photographic image thus produced, and they were successful in devising an automatic machine which effects development in five or six seconds and fixing in six or seven seconds, the paper being then delivered almost completely dry, with only a slight dampness on the gelatine surface. It is stated that strips containing 10,000 or 12,000 words are successfully handled in this way. The speed of the telegraph as a whole is limited by the speed at which the perforations can be made—about 300 letters a second. Several perforating machines can, however, be used to feed the transmitter, and it is said that as many as 50,000 words an hour can be received, though the number, of course, varies with the length and nature of the line in use. In some experiments made by the Hungarian postal department between Budapest and Pozsony, a distance of about 136 miles, with two copper telephone wires of 3mm. diameter, the transmission of 45,000 words an hour was found possible; while in another case, between Berlin and Königsberg, the maximum was about 40,000 words over a distance of 440 miles with wires 4½mm. in diameter. Experimental telegrams were successfully transmitted at the Carlton Hotel over an artificial line equal to 250 miles. The British Post Office is reported to be carrying out some trials with this apparatus.

Northampton Institute.—The prize distribution and conversazione at this foundation took place on Friday and Saturday last, Mr. L. B. Sebastian, chairman of governors, presiding. There was a large and distinguished attendance, including Mr. Alexander Siemens, Mr. J. Gavey, Mr. W. H. Patchell, and members of the governing body of the City of London College, Birkbeck College, the Central Governing Body, the London County Council, the City Companies, and Finsbury Borough Council, while the prizes and certificates were presented by Lord Reay. The principal, Dr. R. Mullineux Walmsley, had an eminently satisfactory report to present to his audience on the expansion of the institute's work, especially on the technical side. The students in the electrical engineering section (evening classes) number 500, the telegraphists and telephonists, under arrangement with the Post Office, are almost as numerous, and there are 300 students in the department of mechanical engineering. The day classes are also progressing admirably. The increase would have been larger had it not been found necessary to stop the enrolments in certain classes in the electrical engineering department, and it may be remarked that this feature has been very much accentuated during the current session, when within the first week several important classes were completely filled, and later applicants had to be refused admission. This shows the great need for the further extension of the accommodation of the institute if its usefulness is not to be seriously curtailed. Not only is it impossible to accept all the students offering for the present classes, but also the further development and improvement of the teaching in these classes, as found advisable by experience, is arrested. The work of the institute, it is gratifying to see, has met with largely increased recognition from the Board of Education. In the technological examination the number of passes from this institute during the past season has been greater than that of any similar institute in the Metropolis, and these successes were accompanied by a fair number of medals and prizes open to competition all over the country. Amongst these may be mentioned the first prize in the honours grade in telephony, and the first prize in the ordinary grade in electric light and power, in telegraphy and telephony, and in watch and clock making. Dr. Walmsley was very hopeful of last year's London Education Act, and attributed a large measure of the success gained during the past season to the generous support of the Technical Education Board of the London County Council. The newly-constituted department of technical optics has been overcrowded, and Dr. Walmsley thought there was reason for hope that Clerkenwell would recover its position as the centre of that industry, especially as the Company of Opticians and Spectacle Makers and the local traders were lending liberal aid. The social side of the institute has also been very successful. In conclusion, Dr. Walmsley thought it might be safely asserted that the institute is doing well the work for which it was established, and that it has shown that it is prepared to make good use of any additional ways and means and of any further opportunities which may be placed within its reach. Lord Reay, before presenting the numerous prizes and certificates, congratulated Dr. Walmsley and Dr. Drysdale upon the progress that had been made. He emphasised the need of technical instruction being the paramount consideration in such institutions, and entirely approved of the lines on which the Northampton Institute had been developed. Several other speeches followed, Mr. Piggott, L.C.C., imparting the felicitous information that the Board of Education has reformed. It now took a real interest in its functions, and on a recent occasion, as on the evening under notice, he saw a representative of the Board on the platform—an unprecedented incident. Mr. Alexander Siemens proposed a vote of thanks to Lord Reay, which was accorded unanimously. A conversazione took place the same evening, and was continued on the following night, when a number of attractive features were provided.

MESSRS. EVERETT, EDGCUMBE, AND CO.'S LONDON WORKS AND SOME OF THEIR SPECIALITIES.

It is not so much our intention to describe here Messrs. Everett, Edgcumbe, and Co.'s works at Great Saffron-hill, Holborn-circus, E.C., as to bring to the notice of our readers some of the electrical instruments which have contributed so largely towards making the firm's reputation. Indeed, a detailed description of the former would scarcely be justified, since the scene of Messrs. Everett, Edgcumbe, and Co.'s activity is to be transferred to Hendon, where they are about to establish new works on a scale more commensurate with their requirements. The plans for these works were in course of preparation at the time of our visit to Great Saffron-hill some few weeks ago. It is no new discovery that the heart of London affords too little expansion room for an increasing manufacturing business, and that the firm in question have been able to remain in it so long is due no doubt to the relatively small space which suffices for the manufacture of electrical instruments on a large scale. However, there is a limit to the capacity of any works, and this limit has been approached in the present case, thus making it necessary to seek a suitable site elsewhere. By moving into the country, Messrs. Everett, Edgcumbe, and Co. will not only obtain more room wherein to expand, but also be able to reduce the cost of producing their goods, and so strengthen themselves against the growing competition which is felt even in this special branch of the electrical industry.

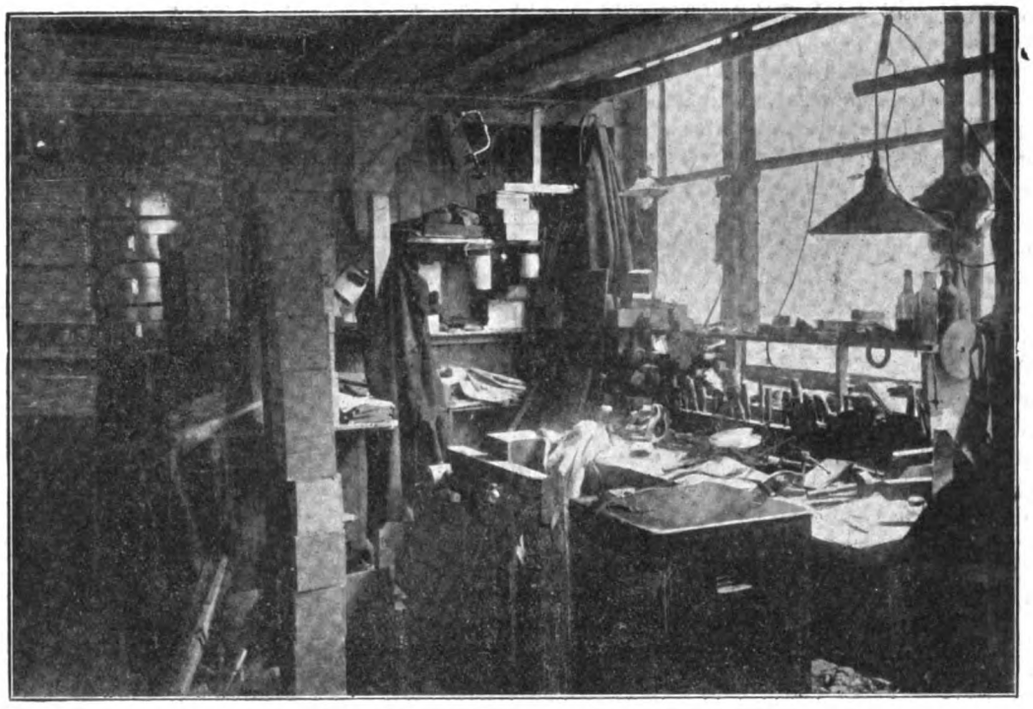

FIG. 1.—Corner of Cabinet-Making Department—Everett, Edgcumbe, and Co.'s Works.

Having regard to the facts stated, it follows that the accompanying interior views of the firm's present works are destined to become historical at no distant date. Upon entering the works, we pass through the showroom and main shop to the cabinet-making department (a corner of which is shown in Fig. 1), for it is here where the manufacture of the firm's portable wood-cased instruments may be said to commence, and these instruments, as distin-

guished from those in metal cases for switchboard use, represent no inconsiderable portion of the total output. Users of these instruments know the excellence of their exterior finish, and we shall see presently that an equal amount of care is taken with the concealed parts, which is really more essential. Opposite the cabinet-making

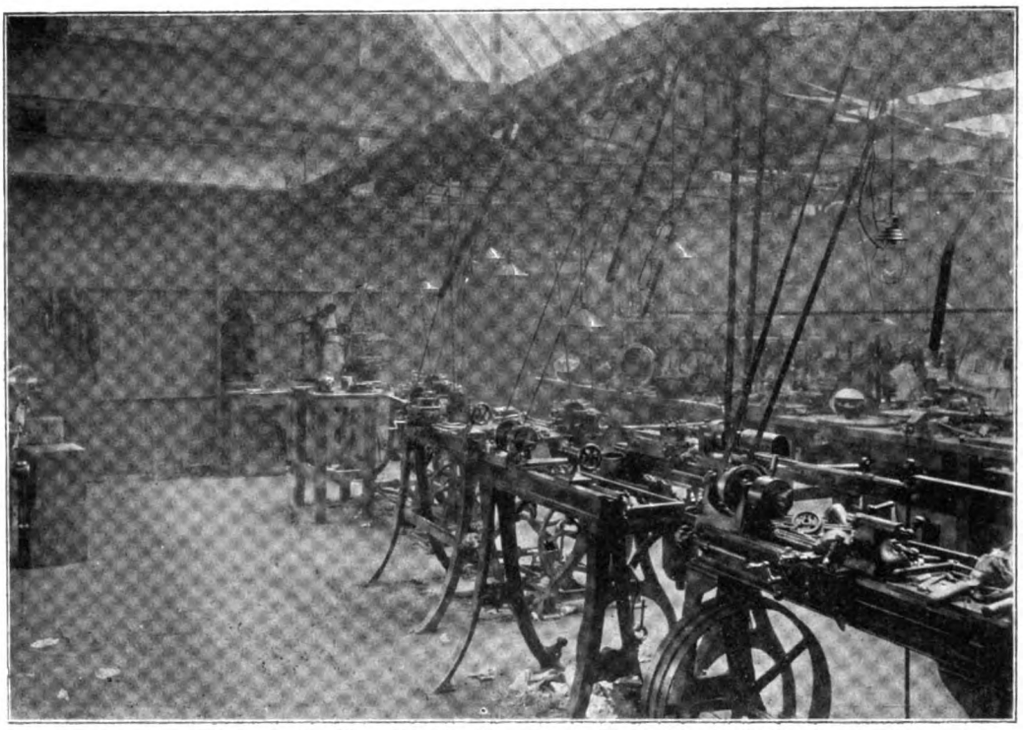

FIG. 3.—Another View of Machine Shop—Everett, Edgcumbe, and Co.'s Works

department is the store for raw material. Here we see iron, copper, and brass in rod, tube, and sheet form; metal cases, rough castings, and an endless variety of components in a crude state, besides finished parts of minor importance, such as screws of ordinary standard sizes. It is not possible to take a photograph, the space being too crowded, so

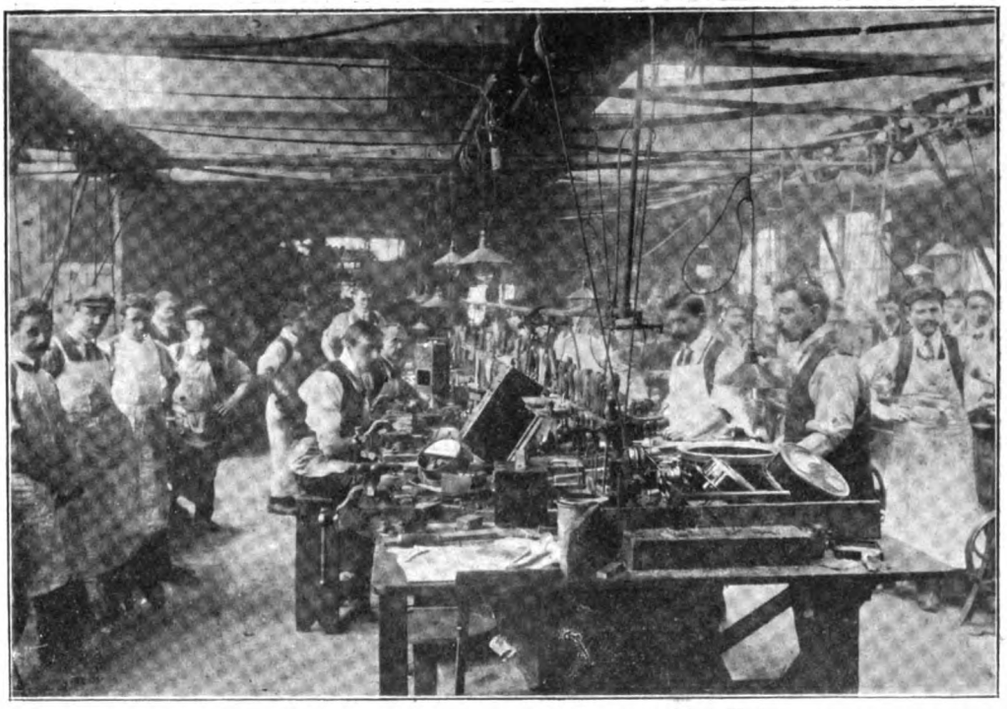

FIG. 4.—Workmen at Benches—Everett, Edgcumbe, and Co.'s Works.

we turn our attention to the machine shop (Figs. 2, 3, and 4), where an array of small machine tools and workbenches meets our view. The machine tools are engaged in turning out standard parts; they are of the semi-automatic type. Here are machines making parts for insulation testing sets, synchronisers, etc, and there capstan lathes fashioning ebonite bushes for insulated terminals, and so on. Jig and circular saws for cutting fibre, wood, and other materials, disc emery wheels, stamping machines, drills, etc., also, we note, find employment in this shop. Our attention is called at one point to a pile of external resistances for voltmeters, and at another to some neat little oil-coooled transformers destined for use in conjunction with power-factor indicators, all made on the spot. We linger awhile to watch the process of lacquering carried on in the department partitioned off for that purpose, casually examine an interesting machine designed by Mr. Everett for printing recorder charts, glance round the racks in the tool store, and then return through the machine shop and packing department to a stairway leading to the first floor (Figs. 5 and 6), on which the parts from the machine tools and benches are ultimately assembled, and the finished instruments calibrated. Here we are shown the racks containing stocks of components all ready for assembling. The machine shop below is organised to replenish these stocks as the demand

Digitized by Google

may require. In this way a sudden run on any particular instrument can be met without a large stock of the finished article being kept. Close to these racks girls are busily occupied in winding coils of the several descriptions used, including small resistances. Great care is taken, we notice, in assembling the different parts of an instrument, as also with the subsequent calibration. From the set of readings taken for each instrument a curve is plotted from which a scale is drawn direct by means of an ingenious machine designed especially for the purpose. In other words, a special scale is drawn for each instrument. The standard instruments used for checking the readings are themselves systematically compared with other standards, so as to eliminate the possibility of error. Continuous-current, single and three phase generating plant for testing purposes, charging accumulators, etc., is installed on the same floor. Neither this nor the stocks of finished instruments are, however, shown in the accompanying illustrations.

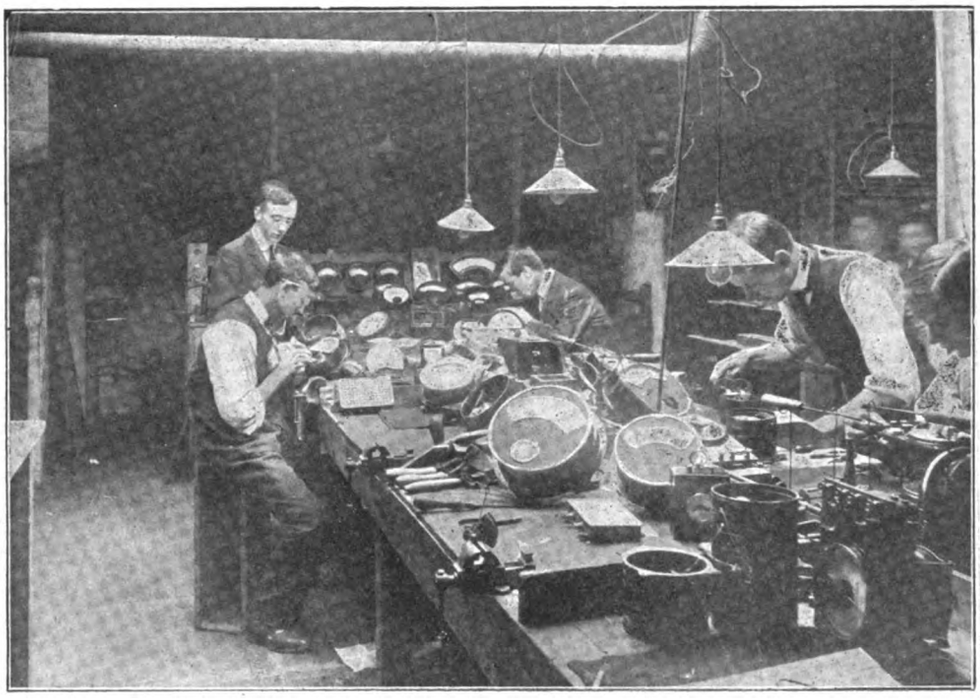

FIG. 5.—Putting Instruments together—Everett, Edgcumbe, and Co.'s Works.

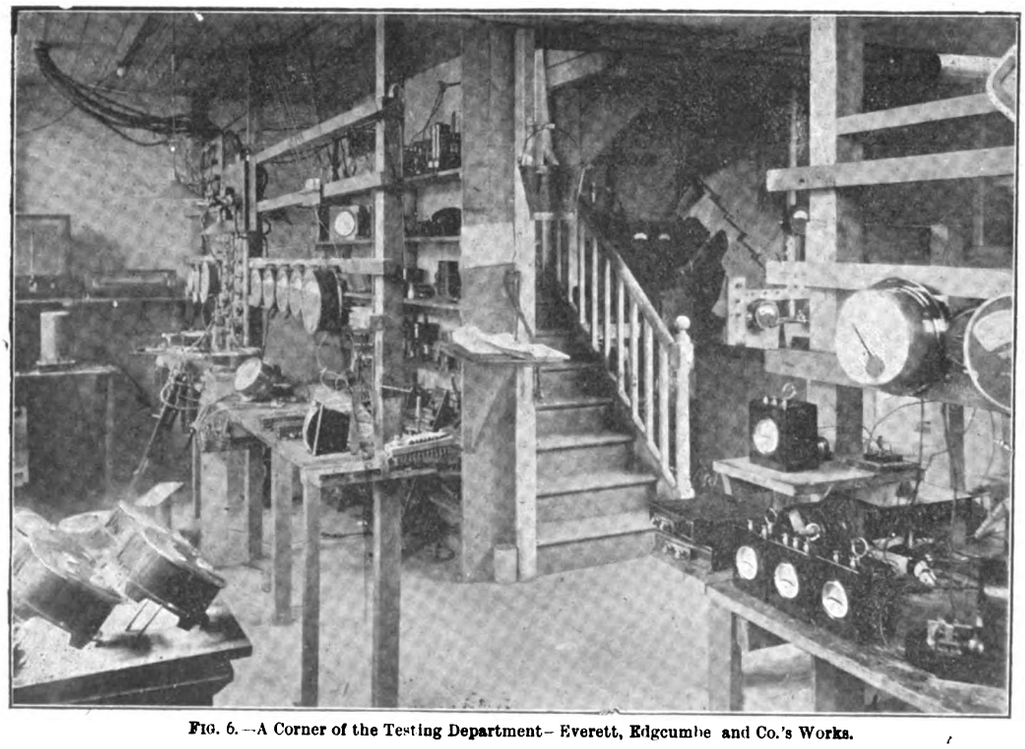

FIG. 6.—A Corner of the Testing Department—Everett, Edgcumbe and Co.'s Works.

Having thus briefly dealt with Messrs. Everett, Edgcumbe, and Co.'s works, we may now proceed to describe some of the more largely used instruments of their design and manufacture. The accompanying illustration (Fig. 7) shows their rotary synchroniser, which is meeting with considerable favour from central-station engineers. This instrument serves to indicate (1) whether the incoming machine is running too fast or too slow; (2) by how much it is out of step; (3) the precise moment for switching in. It is based upon the fact that if the rotor and stator of a rotary-field asynchronous motor be supplied from two sources of alternating current of nearly the same frequency, and be so connected that both fields rotate in the same direction, the rotor will revolve at such a speed as will enable the fields to revolve "in step." In the actual instrument the rotor and stator are each provided with a two-phase winding. In the case of a two-phase system, suppose the rotor to be connected to the terminals of the generator

Digitized by Google

to be paralleled, and the stator to the 'bus bars. Then, if the frequencies be the same, the fields will revolve at the same speed, and there will be no tendency for the rotor to move. If, however, the frequencies are different, then the rotor will revolve in one direction or the other according to which of the two sources has the higher frequency, the speed being such that one revolution of the rotor corresponds to two complete cycles. The rotor axle carries a pointer which revolves in front of a dial, and is so set that when the frequencies are equal it stands vertical. In practice, in order to simplify the connections and to make the instrument applicable to single-phase systems, the

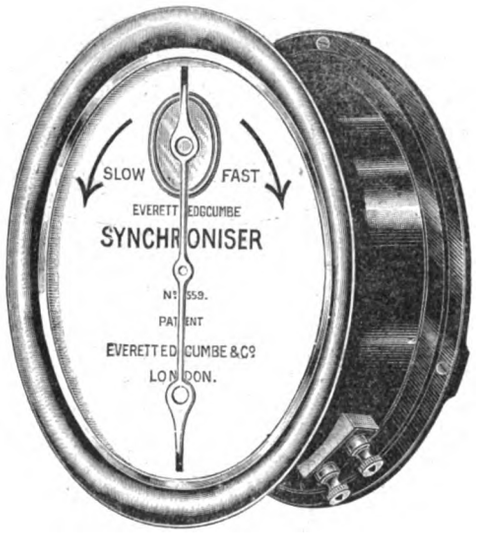

FIG. 7.—The Everett-Edgcumbe Rotary Synchroniser.

necessary two-phase currents are produced by means of choking coils in two of the circuits and non-inductive resistances (lamps) in the other two.

The accompanying diagram (Fig. 8) shows the method of connecting the synchroniser in circuit. A single-phase circuit is shown for convenience. In the case of a two or three phase circuit the synchronising operation is carried out on one phase only, so that only two transformers in all are required instead of four or six, as is the case with most other synchronising devices, and as the current taken is small (from $\frac{1}{2}$ to $\frac{3}{4}$ of an ampere) the ordinary synchronising or voltmeter transformers can be employed for this purpose. An important feature of the apparatus is the ingenious method by which the direction of rotation of the pointer is made visible at a distance from the switchboard—for example, at the engine. This is done by means of a

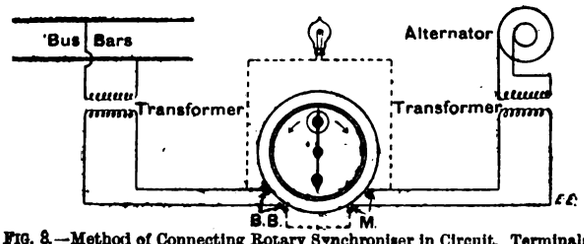

FIG. 8.—Method of Connecting Rotary Synchroniser in Circuit. Terminals marked B B connected to 'Bus Bars. Terminals marked M connected to Alternator.

movable vane, which obscures either a red or a green lamp, seen through an opening in the dial (see Fig. 7), according to whether the hand is revolving to the right or to the left. Thus the engine-driver can see at a glance whether his machine is running too fast or too slow. Further, on the top of the instrument can be mounted an ordinary synchronising lamp, from which he can see by how much his machine is out of step. In several large stations an addition has been made, consisting of an auxiliary contact attached to the red and green shutter, by means of which coloured lamps or other signals can be actuated at a distance from the synchroniser. The instrument is usually constructed for 100 volts, and is provided with a dial some 12in. in diameter. The current is led into the rotor by means of special rod brushes, and the rotor itself runs in ball bearings, and the whole is so simple that there is no likelihood of anything getting out of order.

The design of wattmeters has also been specialised by Messrs. Everett, Edgcumbe, and Co., who make these instruments in two forms, respectively for switchboard and portable use. Both are constructed on the dynamometer principle, in which a fixed current coil acts on a small pivoted coil connected in series with a large non-inductive resistance, and carrying a current proportional to the voltage. The switchboard pattern is shown in Fig. 9 herewith. The errors to be chiefly guarded against in wattmeters are: (1) self-induction in the moving coil, which causes the current to lag behind the voltage; (2) capacity in the moving-coil circuit, causing the current in it to lead; (3) eddy currents in neighbouring metal parts—as, for example, the conductors themselves or their supports,

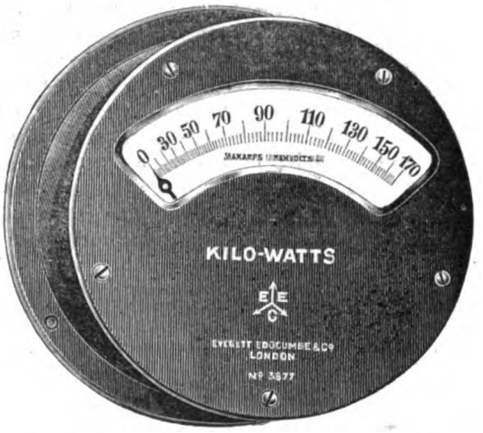

FIG. 9.—The Everett-Edgcumbe Switchboard Pattern Wattmeter.

All these errors have been most carefully avoided in the instruments in question. The series resistance of the moving coil is not only wound non-inductively, but is also wound in sections, whereby the capacity, which is often a serious item, is rendered quite negligible. The series resistance forms a very large proportion of the total resistance of the moving circuit, so that the self-induction of the moving coil is quite swamped, as is also its temperature coefficient. In order to reduce eddy currents to a minimum the current coils are most carefully laminated, and metal parts are dispensed with as much as possible, metal having a very high specific resistance being employed where such cannot be avoided. At the same time, the construction is thoroughly mechanical, and a rigid frame of German silver

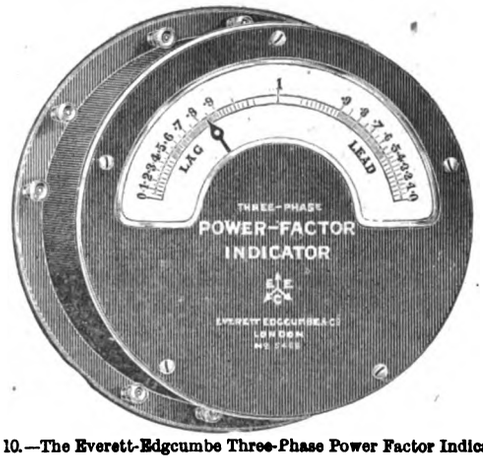

FIG. 10.—The Everett-Edgcumbe Three-Phase Power Factor Indicator.

is used to hold the parts securely in place. Special care is taken with the design of the current and voltage transformers, iron of the best possible quality being used. The magnetic circuit is as short and as perfect as possible, and in the case of the current transformers, the ohmic resistance of the secondary circuit (including transformer and winding) is reduced to a minimum, while the self-induction is considerable. This has the result not only of ensuring that the current in the secondary is strictly proportional to the current in the primary irrespective of changes of frequency, but also that the phase relation between them remains the same at all loads. The instruments are fitted with the Everett-Edgcumbe "air-damping" device so as to render

Digitized by Google

them practically dead-beat, and the scales are extremely evenly divided. The switchboard pattern, which measures about 10in. over the base, has scales 6½in. long, and the case is constructed throughout of insulating material, so as, in the first place, to avoid eddy currents, and, in the second place, to make it quite safe for use on high-tension circuits. It is the practice now to use wattmeters in connection with series transformers, so that the high tension is not led into the instrument itself.

Our next illustration (Fig. 10) shows one of the firm's power-factor indicators for three-phase circuits. As ordinarily constructed, power-factor indicators are of two types: (1) instruments which show merely the wattless component of the power, and (2) instruments showing the actual power factor or angle of lag between amperes and volts. Those manufactured by Messrs. Everett, Edgcumbe, and Co. belong to the second class. They have the advantage of being independent not only of the voltage of supply, but also of the frequency and wave-form. This is a unique feature, as the usual construction, in which a phase difference is produced by means of an inductive and a non-inductive resistance, is, of course, only accurate at one particular frequency and wave-form. In the case of a balanced three-phase load, the instrument consists of a fixed coil inserted in one of the lines, and three volt coils fixed at an angle of 120deg. to each other, and carried by a spindle, which also bears an indicating pointer. Each of

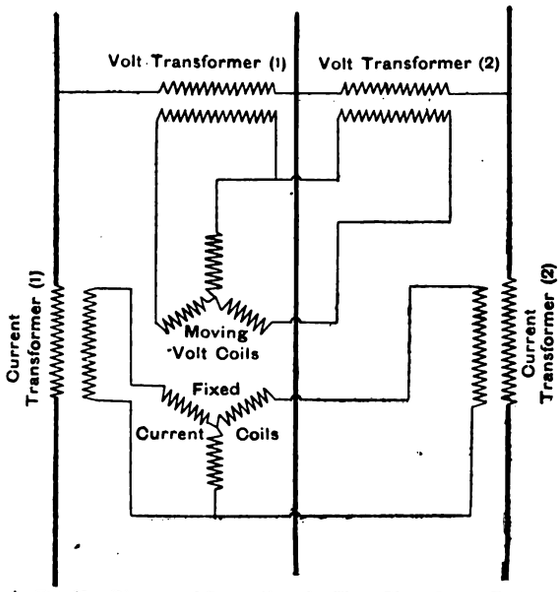

FIG. 11.—Diagram of Connections for Three-Phase Power Factor Indicator on Unbalanced Load.

the three moving coils has one end connected through a series resistance to one of the three conductors. The three remaining ends are joined together, and form the neutral point. A rotating field is thus produced, and the system will set itself in such a position that at the moment the current in the fixed coil reaches its maximum value, the field due to the moving system lies along its axis. In the case of an unbalanced system three fixed coils are employed, set at an angle of 120deg. to each other, and one being inserted in each line. The moving system then takes up a position corresponding to the average power factor of the whole system, and if a short-circuiting plug is inserted in each of the circuits, it is possible to obtain either the average power factor of the system or the power factor of each phase separately. The internal construction of these instruments is on the same lines as that of the wattmeters previously described, and the same remarks as to metal, etc., apply. It should be noticed that both the controlling and deflecting forces are electrical, so that when no current is flowing the pointer will not take up any definite position. The current coils are so proportioned that there is ample power even at one-tenth of the full load. The dial is non-metallic, and the case is constructed of insulating material.

The connections for a three-phase unbalanced load are shown in Fig. 11. The arrangement is such that two voltage transformers and two current transformers alone are required. This is preferable, owing to the fact that the necessary transformers are, as a rule, available in connection with the integrating wattmeters, which now usually find a place on the switchboard. When the load can be regarded as balanced—as, for example, in the case of a motor—only one coil is necessary, but even in this case it is preferable, when possible, to use three coils. A special feature of this arrangement consists in the connection of the third current coil in series with the other two, whereby only two current transformers are necessary. Seeing that the current in the third line must be equal at each instant to the resultant of the currents in the other two, it is

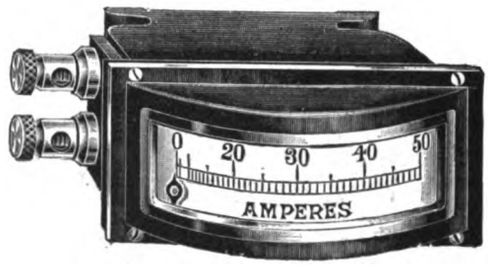

FIG. 12.—The Everett-Edgcumbe Small Edgewise Ammeter.

unnecessary to connect this third line to the instrument. In place of the two single-phase volt transformers, one three-phase transformer can, of course, be employed, and in the case of low-tension systems the volt transformers are replaced by a star resistance. The instruments are usually fitted in 8in. round cases (see Fig. 10), but can also be supplied in portable form. They are equally adapted, it may be added, for two or three phase circuits.

Reference may also be made to the firm's "Universal" moving-iron ammeters and voltmeters. These instruments have been designed with the object of providing alternating-current ammeters and voltmeters which remain practically unaffected by changes of frequency or wave-form. So well, it is claimed, has this result been attained that it is found incidentally that the instruments, when calibrated with alternating current at, say, 50 cycles, have an error of less than 1 per cent. when tested with direct current, with, of course, a proportionately small error for changes of frequency and wave-form. In order to render the effect of the latter negligible, the induction in the iron is kept extremely low, so that the force acting on the moving iron is at any instant practically proportional to the square of the current and not directly proportional to the current, as is the case when high inductions approaching the saturation point are employed. The effect of frequency is negligible not only in the case of the ammeters, but also in that of the voltmeters. This is secured by means of the special shape of coil used, which is of a flat form, so that the self-induction is extremely small, while the force acting can be made comparatively large. The series resistance of the voltmeters is wound on open frames fixed at the back of

FIG. 13.—The Everett-Edgcumbe Direct-Reading Ohmeter.

the case, and the wire itself is protected by a coating of waterproof varnish. To render these instruments dead beat for use with variable loads, a special air-dashpot has been devised, which, owing to the fact that the piston does not touch the cylinder at any point, introduces no friction or sluggishness, and is a great improvement on the oil dashpot on the one hand, and magnetic damping

Digitized by Google

on the other, which in the case of moving-iron instruments is practically useless owing to its effect on the readings with direct current and to the magnets becoming rapidly demagnetised when used with alternating currents. For use on high-tension circuits these instruments are supplied to work off current and voltage transformers. The former are specially designed to introduce no error through frequency changes, and are similar to those employed with the Everett-Edgcumbe wattmeters. In the case of the voltmeter transformers, the insulation receives special care.

If asked why ammeters and voltmeters should almost invariably be fitted into round cases, it would probably be difficult to find a satisfactory answer. It is certainly not because they thereby occupy less space or are more convenient to read. A refreshing departure has been made by Messrs. Everett, Edgcumbe, and Co. in their small edgewise instruments, one form of which we illustrate in Fig. 12. In this instrument a scale 4½in. long is obtained—that is to say, of the same length as the ordinary round instruments 7in. or 8in. in diameter, whereas the actual space occupied is only 6¾in. by 3⅛in. The actual saving in space is really considerably greater than these figures would seem to indicate, due to the fact that the convenient shape of these instruments enormously simplifies the setting out of the board, as they can be fitted in between the switches, etc., or can be placed horizontally along the top of the board.

These meters are supplied in two distinct forms, respectively for mounting on the surface of the switchboard or for letting into it. Each type can be supplied either with horizontal or vertical scale, as preferred.

This article would not be complete without some reference, however brief, to the firm's direct-reading resistances and insulation indicator. These instruments work on the Wheatstone bridge principle, but are so arranged as to be absolutely direct reading. This is obtained by means of a special high-resistance slide-wire arrangement fixed to a central axle carrying a milled head, which in turn is provided with a pointer moving over a scale so graduated as to read direct in ohms or megohms, as the case may be. The standard resistances are connected to a change-over switch, three being provided in the case of the insulation sets and five in the case of the resistance sets. The former sets have a range of reading from 10,000 ohms to 50 megohms, and the latter from one-tenth of an ohm to 11,000 ohms. The galvanometer, which is also fixed in the same case, is an important feature of these sets, in that, in the first place, there are no pivots, and, in the second, no careful levelling is necessary. This galvanometer is of the D'Arsonval type, and consists of a small round coil swinging in a circular air-gap. The coil carries a pointer, which is seen through a small opening at the top of the case. The zero of the galvanometer can be adjusted, should this be necessary, by turning a brass milled head. In the centre of the ebonite milled head is a small galvanometer key, which can be depressed with the same hand as that which moves the milled head. It may be added here that the over-all size of this new departure in Wheatstone bridges is 9¼in. by 6½in. by 6½in.

The outward appearance of one of these instruments is shown in the last of the illustrations herewith (Fig. 13). For use with the same a compact form of magneto-generator giving 100, 200, or 500 volts, as preferred, is supplied when insulation measurements are to be made. The whole is arranged so that one operator can easily work both the ohmmeter and the generator, with the further advantage that the two instruments can be placed as near together as may be convenient, owing to the fact that they are quite unaffected by stray magnetic fields.

The generators are provided with special commutators having eight parts, and so sub-divided that, in the first place, the insulation for high voltages is easy, and, in the second place, the turns on the armature are all connected in series instead of in parallel, which, for a small machine, is a considerable advantage. The armature runs in ball bearings, and is so easy to turn that it can be readily worked with one hand. Carbon brushes are also fitted to prevent sparking and wear of the commutator. Capacity has no effect on the actual accuracy of the readings; it merely shows itself by a vibration of the galvanometer pointer when the generator is turned slowly, the position of balance being unchanged. This, of course, assumes that the generator is turned approximately evenly, or the rushes of current will make the balance difficult to obtain.

In the foregoing we have purposely confined our attention to such only of Messrs. Everett, Edgcumbe, and Co.'s specialities as more directly concern station engineers. We have, in conclusion, to thank Messrs. Everett, Edgcumbe, and Co. for the assistance they have given us with the preparation of this article.

THE ELECTRIFICATION OF THE METROPOLITAN RAILWAY.

In England no function from a christening to a funeral is reckoned complete unless there is a meal attached. This was exemplified on Tuesday last, when the inauguration of the electric service on the Metropolitan Railway was the occasion of a lunch, at which representatives from all the leading railways in the kingdom were present. It is too much to expect, however, that one lunch will act as the christening of the electric service and the funeral of the steam traffic on the Inner Circle. The function of Tuesday must, therefore, be considered solely as a christening one. The doom of the steam locomotive on the Underground is certain, but the exact date of the funeral has yet to be fixed. This public rejoicing when the change has been completed will, perhaps, render a second function unnecessary. Among those present were the following gentlemen: Sir Charles McLaren (chairman of the Metropolitan Railway), Colonel J. J. Mellor, Lieut.-Colonel Clifford Probyn, Mr. Jabez Light and Sir William Birt, directors of that line; Colonel William Terry, director of the Harrow and Uxbridge Railway; Major L. H. Isaacs, of the Metropolitan District Railway; Mr. G. J. Churchward, of the Great Western Railway; Mr. V. W. Hill, of the South-Eastern and Chatham Railways; Mr. G. C. Cunningham, of the Central London Railway; Mr. T. C. Jenkin, of the City and South London Railway; Mr. Sam Fay, of the Great Central Railway; Mr. J. F. S. Gooday, of the Great Eastern Railway; Mr. W. J. Grinling, of the Great Northern Railway; Mr. J. A. F. Aspinall, of the Lancashire and Yorkshire Railway; Mr. W. Forbes, of the London, Brighton, and South Coast Railway; Sir Frederick Harrison, of the London and North-Western Railway; Sir Charles Owens, of the London and South-Western Railway; Mr. A. L. Stride, of the London, Tilbury, and Southend Railway; Mr. Wilson Worsdell, of the North-Eastern Railway; Mr. F. J. Dunn, of the North London Railway; Mr. James R. Chapman, of the Underground Electric Railways Company of London; Mr. H. Smart, of the Railway Clearing House; Sir Wolfe Barry, Sir Frederick Dixon-Hartland, Sir Ralph Littler, Prof. A. B. W. Kennedy, and Prof. S. P. Thompson. Mr. A. C. Ellis, the general manager, Mr. T. Parker, the consulting electrical engineer, and the other chief officers of the Metropolitan Company were also present.

Sir CHARLES MCLAREN, the chairman of the company, presided at the lunch, and explained that the transition from the steam service to the electric trains would be gradual. He gave us to understand that it will be commenced on the Baker-street-to-Uxbridge line by the gradual interpolation of more and more electric trains into the steam service. He hoped that by Jan. 1 the whole of this service would be electric, and then the advantages from the improved acceleration and higher mean speeds will begin to be realised. He assured those present that they were working night and day to complete their arrangements for the electrification of the Inner Circle. In this the Metropolitan District Railway was also concerned, but he saw no reason to doubt that the two companies would be ready much at the same time. While the Metropolitan Railway draw their supply of electricity from Neasden, the District will get the necessary energy from their large works at Chelsea, but arrangements had been made for the interchange of current if necessary. Sir Charles McLaren emphasised the care the company have taken

Digitized by Google

to secure public comfort and absolute safety. It will be news to some who are not acquainted with the early history of the Metropolitan line that the tunnels were made to take the broad-gauge trains of the Great Western Railway Company. It followed from this that the space in the tunnels is ample, and hence when once the steam-engines have been removed and the tunnels cleaned and whitewashed the atmospheric conditions will be revolutionised by the electric service. Instead of the atmosphere in the tunnels being, as we should term it, the worst in any railway in London, it will become much purer than that in any tube line, owing to the ample space between the trains and the tunnel. It was also explained that every care had been taken to make both the trains themselves and also the stations fireproof, so as to avoid any risk of fire being caused electrically. In conclusion, Sir Charles McLaren expressed the hope that with the increased facilities and lower fares the increase of traffic would be such as to recoup the company not only for the cost of electrification, but would also return larger profits on the original stock.

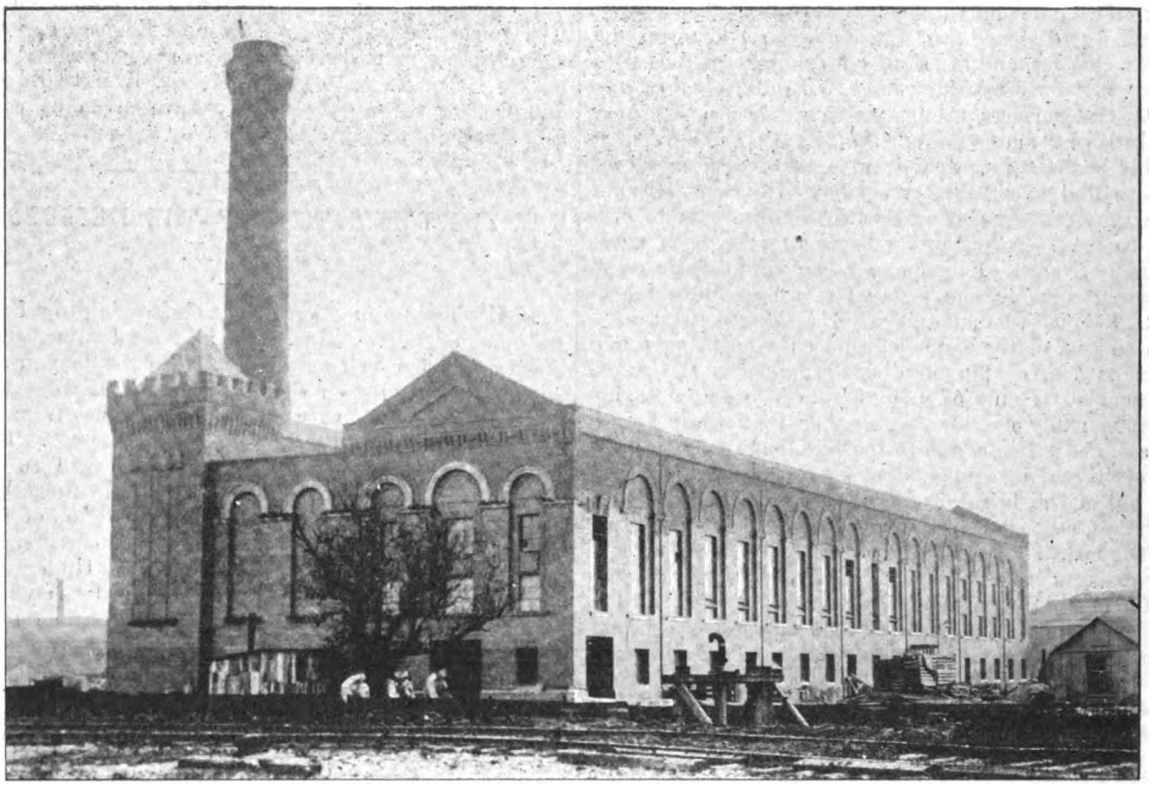

FIG. 1.—The Neasden Power House of the Metropolitan Railway Company.

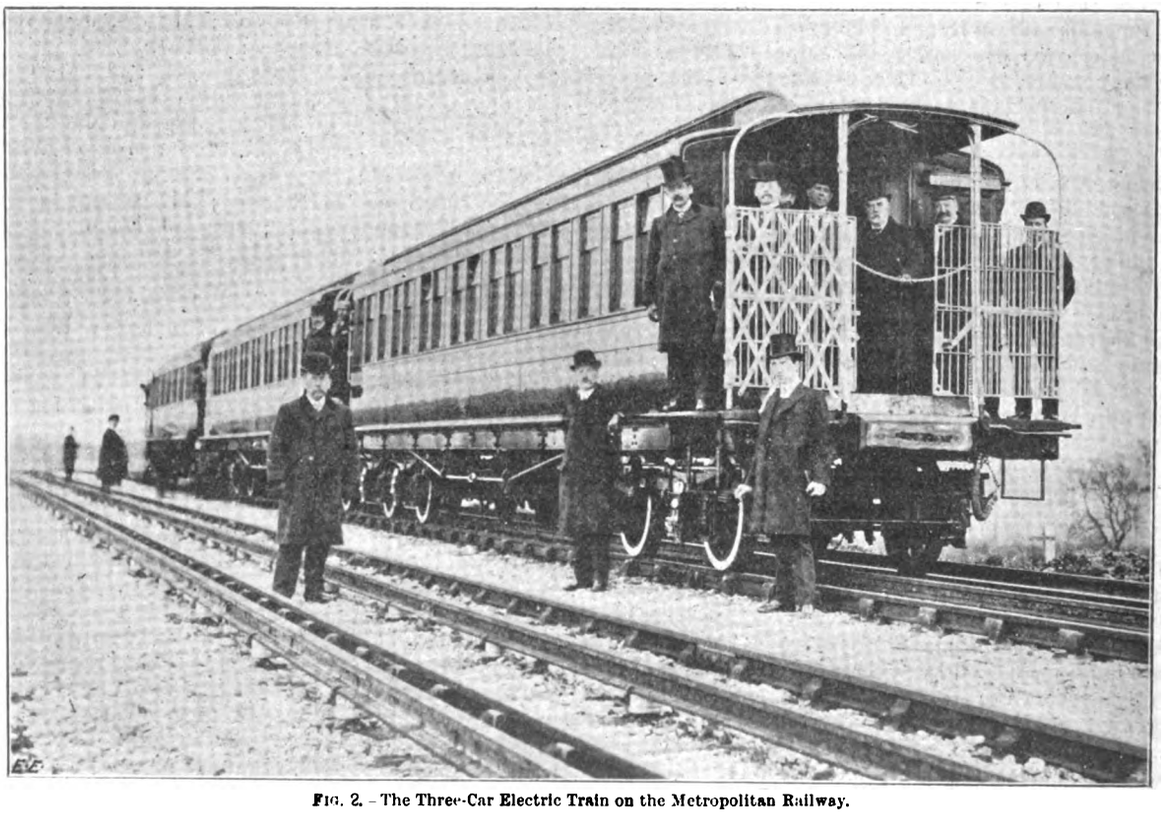

FIG. 2.—The Three-Car Electric Train on the Metropolitan Railway.

After the few remarks of the chairman there was no more speechmaking, and the company proceeded from the Great Central Hotel to Baker-street, where a six-car electric train was in waiting. In this there was ample accommodation for all present. A non-stop run was then made to

Digitized by Google

Uxbridge, the time taken on the journey being about 35 minutes. There was, of course, on this occasion no attempt made to get maximum speed, as the train had to e run without interference with the ordinary traffic. After a short stop at Uxbridge, the return journey was made in much the same time, with only one slight stop outside Baker-street. For this return journey we secured a good point of observation in the guard's van. Standing by the door into the driver's compartment, we were able to watch with interest the ease with which the heavy train was controlled on the Westinghouse electro-pneumatic system. The controller handle seemed absurdly small for the large horse-power it had the command of, but the slight mechanical effort needed leaves the driver more free to observe the signals, etc. The sparking of the collecting shoes on the third and fourth rails seemed to impress a certain number of those present, but this was entirely due to the oil, rust, and dirt which have accumulated on these rails since they were put down nearly a year ago. On the Uxbridge portion of the line, where the experimental trains had been run more frequently, the sparking at the shoes was inappreciable. A regular service train into and out of Baker-street will soon clean these conductor rails and entirely prevent the flashing in question. The comfort

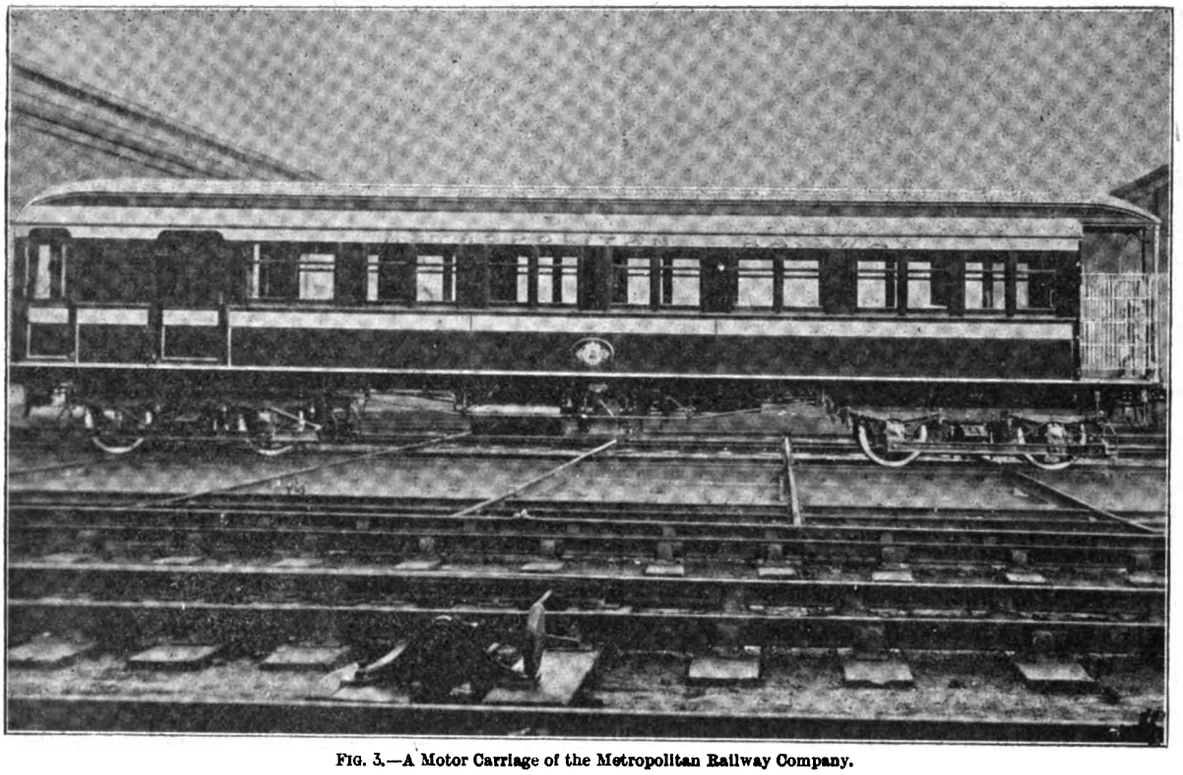

FIG. 3.—A Motor Carriage of the Metropolitan Railway Company.

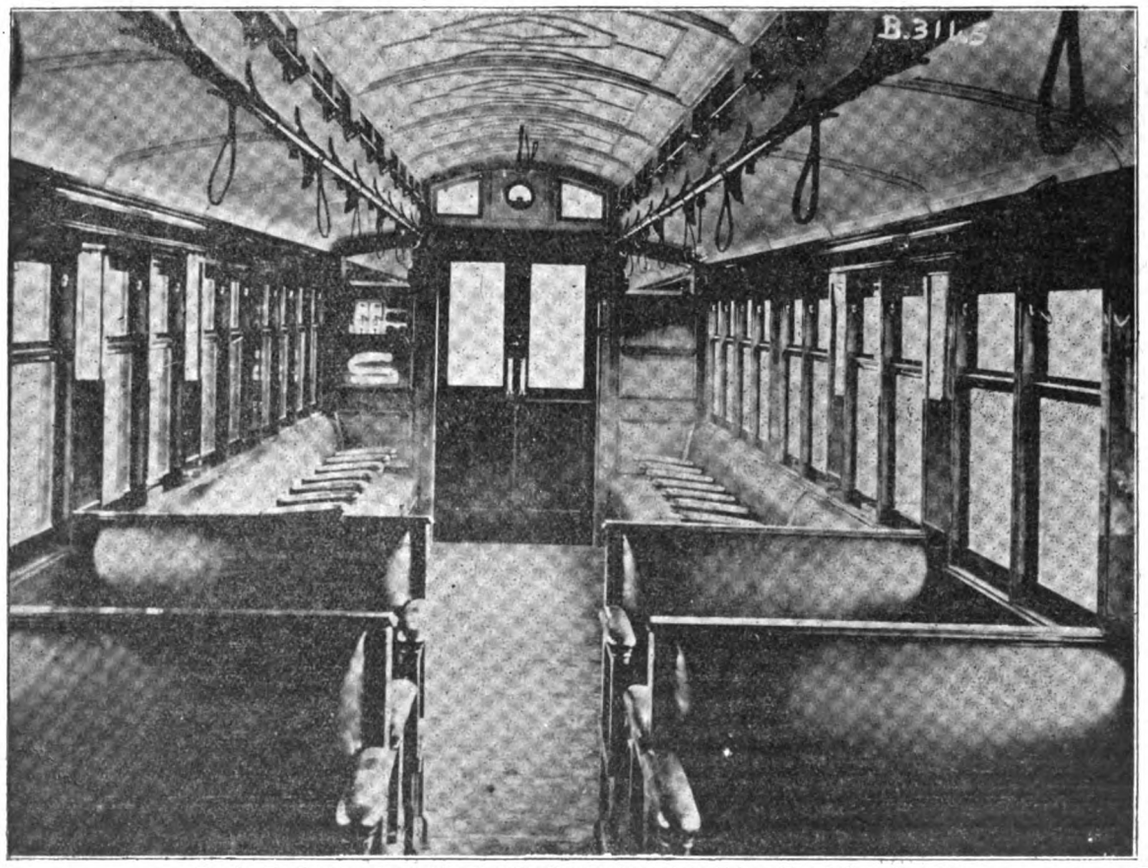

FIG. 4.—The Interior of one of the New Corridor Carriages of the Metropolitan Railway Company.

Digitized by Google

of the carriages, and especially the airiness of the same, was commented on by those present, and the electric heating was a feature by means unwelcome on Tuesday. There is no doubt that with the intermixed system of electric and steam trains there will be a rush for the increased comforts of the former, and these improved carriages will be even more highly appreciated when they replace the rolling-stock now used on the Inner Circle.

With respect to the electrical features of the new equipments, there is very much more to be said than can be put in a single issue of any technical journal. We propose, therefore, to give at the present time an outline sketch which will show the lines on which the Metropolitan Company are working under the advice of their consulting electrical engineer, Mr. Thomas Parker. It will be remembered that the company endeavoured in the first instance to use the high-tension system of three-phase traction working on the Ganz system. The historic arbitration before the Right Hon. Alfred Lyttleton, K.C., brought out the good points of the proposed system, but it was rejected on the ground that it had not been sufficiently tried on a large scale. The company, in consequence, have adopted direct-current motors on their trains, but there are many features which mark a distinct advance on previous practice.

The generating works are situated at Neasden, adjoining the stores and repair department of the line. The site is an excellent one, as water is abundant. The supply is obtained from two artesian wells and stored in a cooling reservoir. The area covered by the building is some 3,570 square yards, the building being 318ft. long and 100ft. wide. The works are designed to contain four three-phase turbo-alternators, of which two are erected and at work. The output of each machine is 3,500 kw. Steam for these steam-turbines is obtained from batteries of Babcock-Wilcox boilers, which are fed by a type of mechanical stoker new to this country. This is the Roney stoker, in which a steep inclined grate is used, down which the fuel gradually falls owing to a rocking motion in the stepped firebars. The coal-handling plant, with its automatic weighing machine to each boiler and the ash-conveying plant, is of the latest design. Each of the boilers in question is capable of evaporating 20,000lb. of water per hour at 180lb. pressure, and of superheating the steam to 520deg. F. The steam leaving the turbines is condensed by barometrical ejector condensers, the steam coming into direct contact with the cold circulating water forced up to the top of the condensers by centrifugal pumps. The condensed steam and circulating water is then forced up to the top cooling towers, and, by falling down over a series of wooden strips, it is cooled down to about 80deg. F. The water passes from the bottom of these cooling towers out into the large reservoir, where it is cooled still further by the exposure of a large surface to the air.

The alternators generate three-phase current at 11,000 volts, and this is then transmitted to the various sub-stations at different parts of the system. There is for the control of these machines and of the distributing feeders no switchboard in the usual sense of the word. The operator has instead before him a comparatively small table on which the circuits are represented in the form of a diagram. The small switches actually inserted in position in this diagram control by electro-pneumatic relays the large switches which are placed in fireproof chambers near by. The movements of these larger switches again operate small instruments on this diagram before the operator, and hence show him exactly which connections are made at any one time. The result is that with the measuring instruments before and the diagram of connections he has much better control of the large system than he could possibly have with any arrangement of switchboards in which the switches are operated mechanically and some distance apart. We had the opportunity of witnessing a parallel running trial on Monday last, which clearly showed the advantages of the small master-board described above.

There are eight sub-stations on the Metropolitan Company's system which receive the high-tension supply at 11,000 volts from Neasden. One of these sub-stations, however, is situated within the generating station itself, so that there are only seven sub-station buildings out on the line. These are situated as follows, commencing from the Uxbridge end of the system. At Ruislip the sub-station is equipped with three rotary converters, each capable of supplying 800 kw. as direct current to the line. In the Harrow sub-station there are four rotaries of the same size, and at Neasden three. The next sub-station coming towards London is at Finchley-road, where there are four 800-kw. rotaries. The largest sub-station is at Baker-street, and here after considerable trouble space has been found for the instalment of four 1,200-kw. rotaries, with their complement of static transformers, high-tension oil switches, etc. Seeing that with a full schedule there will be about 42 trains per hour coming into and out of Baker-street, the need for this heavy equipment will be appreciated. On the Inner Circle itself there is only one sub-station on the westward portion of the line from Baker-street, and this is situated in Bouverie-street, not far from Praed-street Station. This sub-station contains three rotaries of 800 kw. capacity each, as do also the two sub-stations to the eastward at Charlton-street, near King's Cross, and at Moorgate-street respectively. All these sub-stations on the Inner Circle have been so designed that at any time an 800-kw. rotary can be replaced by one of 1,200 kw. capacity.

Of the equipment of the track we do not propose to say much at the present time, except that the company have adopted an insulated return, and are not using the running rails at all for this purpose. Quite apart from the electrical advantages of this course, the separate return is much less likely to give rise to short-circuits than are the running rails when used for this purpose. The new trains are entirely composed of corridor cars, and they will have a motorcar at each end. The new stock has been built at Birmingham and Manchester by the Metropolitan Amalgamated Railway Carriage and Wagon Company, Limited, under the immediate direction of the railway company's carriage and wagon superintendent.

The cars, which are of two classes, are 52½ft. long, and arranged with both transverse and longitudinal seats. The ends of the cars are provided with sliding doors, and patent swing gates lead on to the car platforms. The superior class non-smoking cars are upholstered in art green moquette; the smoking cars being similar in all respects save the upholstery, which is of green leather. All the second-class cars have buffalo hide covered seats, and they otherwise differ from the superior class cars only in that the decorative work is less elaborate. Electrical heaters are fitted to every car. In the construction every provision has been made to ensure the fullest protection against fire, sheet-steel panels, asbestos slate, and other non-flammable materials having been introduced wherever possible and necessary. Each car is mounted on two English manufactured pressed-steel four-wheel bogie trucks. In the case of the motorcars, each of the four axles is driven by a separate iron-clad motor of 150 h.p. normal capacity.

On the complete train of six coaches there must be eight motors of this size, and with the weight carried on the driving axles there will be no difficulty in obtaining high acceleration. It is in the design of the controllers that the special interest lies, and we hope at an early date to give an illustrated description of the same. The master controllers are placed at either end of each motorcar so that there is no difficulty in quickly making up long or short trains. These master controllers operate on a 12-volt circuit the pneumatic switchgear under each motor coach. There are on the master controllers only five notches for forward running and five for backward running. There is, however, in the pneumatic controller under the car an automatic accelerating device which comes into action on the fourth notch of the master controller. The object of this device, which is successfully attained, is to secure uniform acceleration independent of movement of the driving lever, and without an undue draught of current from the third rail. The electrically-controlled pneumatic relays which effect this seem at first sight to be complicated, are a simple development of the pneumatic mechanism of the Westinghouse brakes, which have stood the test of time, and proved absolutely reliable. With the pneumatic switchgear operated with 80lb. per square inch on the compressed air there is ample force to operate the switches with certainty. Another feature of this turret type of controller with the switches arranged in a ring on

Digitized by Google

the under side is that a single blow-out coil can be used, and this can be made much more powerful than if an individual blow-out magnet had to be provided for each switch.

The organisation of this conversion from steam to electric working has been in the hands of Mr. A. C. Ellis, the general manager of the company, with the assistance of Mr. Thomas Parker, the consulting electrical engineer, and Mr. C. Jones, who has been appointed chief electrical engineer. Mr. E. P. Seaton, the company's engineer, has had the direction of the line works; and Mr. A. Ingram, the carriage and wagon superintendent, has supervised the construction of the rolling-stock.

We give herewith a few illustrations of this rolling-stock and also of the generating station. In an early issue we hope to publish interesting details of the plant, drawing special attention to those points in which striking advancement on older practice has been made.

(To be continued.)

KILMARNOCK ELECTRIC LIGHT AND POWER SCHEME.

The busy little town of Kilmarnock, in Ayrshire, with its population of 48,000, was *en fête* on Saturday last on the occasion of the inauguration of its Corporation electric light and power installation. This last and most ambitious of Kilmarnock's municipal enterprises is the result of discussion and negotiation which have gone on since 1898. At that time the growing popularity of electrical energy was brought home to the Kilmarnock people by a private company expressing the desire to take possession of the burgh for electrical purposes. There and then the Town Council engaged Mr. Wm. Arnot, consulting engineer, Glasgow, to look into the matter and report. The result of Mr. Arnot's favourable report was the appointment of an electricity committee, who visited various towns in Scotland to get further information. Opposition to the municipal ownership of the proposed undertaking still persisting among a number of the citizens, Mr. Bryson, of Leith, was next appointed as engineer to the Corporation. This, however, still did not better matters, as the drafting of a scheme and an estimate of the total cost by Mr. Bryson resulted in a majority being against proceeding further with the scheme. So matters remained for over a year, when Dr. Kennedy was invited to report on a scheme of electric light and tramways. Dr. Kennedy was optimistic as to the introduction of electric light, but expressed himself doubtful as to the advisability of going on with the tramway proposals. In the meantime public opinion seems to have ripened under the continued attempts of a private company to annex the burgh, and the result was that the Town Council decided to proceed with the double scheme. A tramway order was obtained, and the whole matter was put into the capable hands of Messrs. Kennedy and Jenkin to carry through. The commission appointed to promote the Bill gave the Town Council three years to carry out the work, and it is gratifying to record that the execution of the entire scheme has occupied only about a year.

The generating station, equipped for both lighting and traction, is situated on the north bank of the River Irvine at Riccarton, a suburb of the town. The front elevation of the buildings is of red sandstone and white pressed brick. The ground floor is set apart for offices. The chief engineer's office, the mains department offices, and the stores are on the first floor. The engine-room is 71ft. 6in. long by 37ft. 6in. wide, and contains four 200-h.p. Belliss engines coupled to dynamos of Messrs. Dick Kerr's make. The jet condensing plant is by Messrs. Mirrlees, Watson, and Co., of Glasgow, and is situated at the west end of the engine-room, where there is room left for a further generating set. The switchboard is placed on a gallery about 3ft. above the engine-room floor level, and has been built by Messrs. Cox-Walkers, of Darlington. The board is a combined one for lighting and traction, and is very compact. The dynamo rheostats are placed immediately under the gallery, and the regulating switches are worked by means of hand-wheels on the switchboard gallery. The arrangement adopted enables them to be placed very close together, thus giving the switchboard attendant complete control without the necessity of moving about. The whole of the switchboard connections, including the shunt leads, are of solid-drawn copper rods, supported on porcelain insulators, practically no cable being used. The battery-room is on the north side of the engine-room, and contains 254 cells of Tudor type, the capacity of the battery being 360 ampere-hours. Only a very few regulating cells are supplied, the booster being kept in circuit practically all the time. The boiler-house contains three Lancashire hand-fed boilers, 28ft. × 8ft. × 160lb. pressure, and are of Messrs. Yates and Thom's make, and there is accommodation for two further boilers. The coal supply is brought in by carts, which are tipped over into bunkers opposite the boilers, but it is hoped that an arrangement will be entered into with the G. and S. W. Railway Company for a railway siding, and negotiations are now in progress towards this end. The boilers are fed by means of two "Weir" direct-acting pumps, which draw water either from the town mains or from the condenser discharge, and can pump either direct to the boilers or through the Green's economiser, which is composed of 192 tubes. A small motor-driven sump pump has been erected in the pump-room alongside the boilers to deal with the drains in times of floods, as the foundations of the station are below flood-level. The pipework has been supplied by Messrs. Aiton and Co., of London, and is covered with Haacke's fossil meal composition, put on level with the flanges, which are themselves covered with planished steel plates. The workshop is situated on the east side of the engine-room, and is suitable for either car or machinery repairs. The car sheds hold 12 cars, 11 of which are now ready. The cars are the work of Messrs. Hurst, Nelson, and Co., Limited, of Motherwell, with the exception of the wheels supplied by Messrs. Hadfield, of Sheffield. The motors and general electrical apparatus for the equipment of the cars have been supplied by Messrs. Witting, Eborall, and Co., London.

The cars seat 52 persons each, and have the ordinary type of staircase, with an extended canopy top. They are painted olive green and cream. One noteworthy feature of the cars is a movable step, which, instead of folding back on itself as is usual, is hung on levers. By this means the step can be swung to one side and upwards by a catch and handle on the platform. When in the raised position, the step is about 16½in. above ground level, and can still be used as a step by the motor-man if he requires to get off his car. The buildings have been constructed and fitted up throughout by local contractors with the exception of the lighting, which is by Messrs. Cox-Walkers. Mr. C. Stanley Peach, of London, and Mr. C. Fairweather, jun., of Kilmarnock, have been the joint architects.

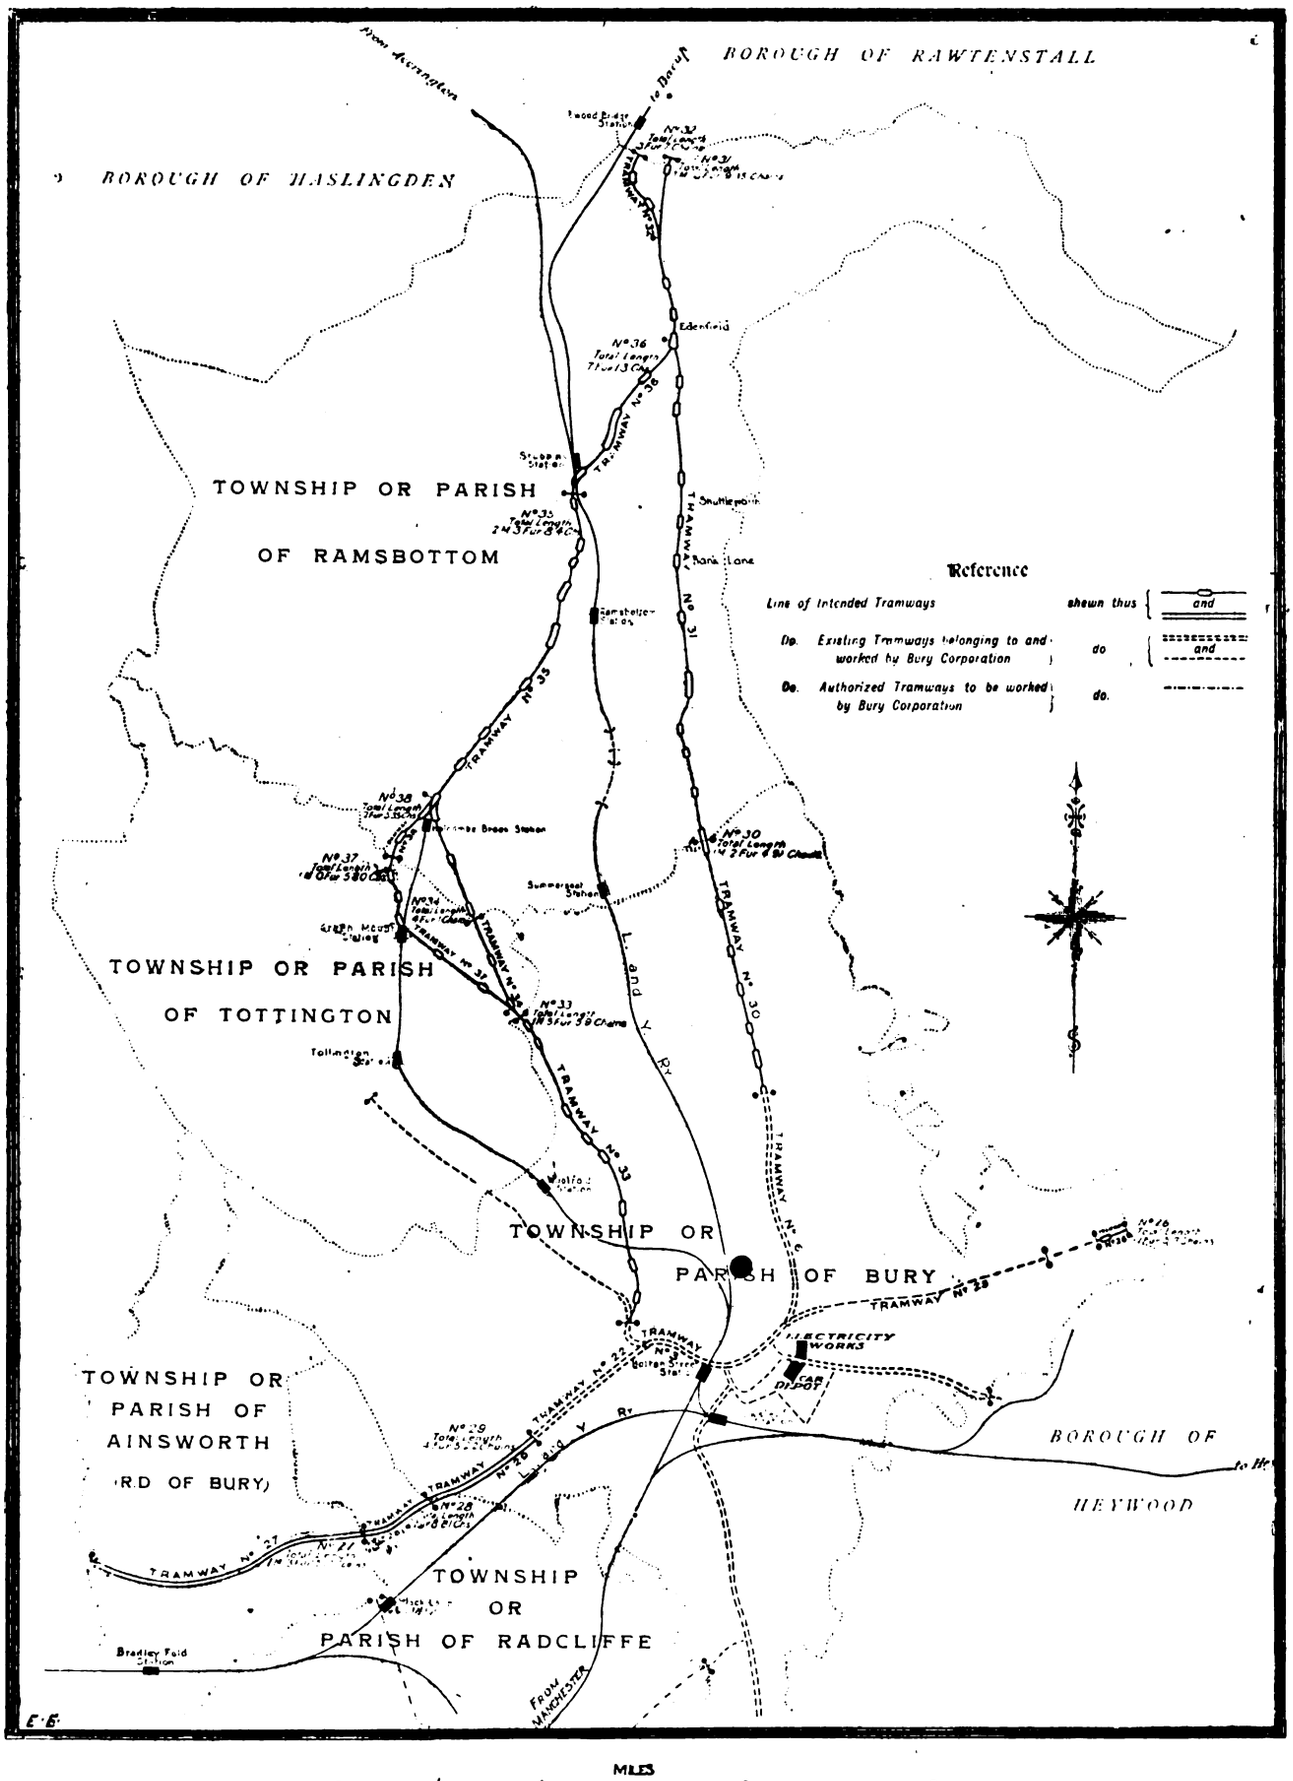
The tramway route consists of a half-mile of double line and 3¾ miles of single line. The track work has been done by Messrs. Dick-Kerr, under Mr. J. E. Tarling's supervision, and the rails are of the 90lb. girder type with the "Dicker" joint, and were rolled by the North-Eastern Steelworks, Middlesbrough. The track is bonded with solid-ended bonds, except at the points and crossings, where drift pin points have been put in. Passing places are arranged about every third of a mile, and the line where single has been laid to one side, as far as possible, to allow for doubling later on if required. The overhead equipment has been supplied and erected by Messrs. R. W. Blackwell and Co. The bracket arm method of carrying the overhead conductors has been adopted for those parts of the route which run through outlying districts, while in the centre of the town the wires have been secured to rosettes. The poles are entirely free from anything like decoration, and have no cast-iron bases. Bronze straight line hangers and pull-offs have been adopted throughout, and the gauge of wire used is No. 00 S.W.G. The cables have been supplied and laid by Messrs. Callender's Cable and Construction Company; their insulation is of impregnated jute, they are lead covered, and laid in wood troughs filled with bitumen and covered with hard brick tiles. Messrs. Callender have also supplied

Digitized by Google

the section pillars and the signalling pillars, each of the latter containing a telephone.

The main thoroughfares of the town are lit with 50 10-ampere open type arc lamps of Messrs. Oliver and Co.'s make, and two incandescent lamps in brackets have been placed on each pillar to light the streets after midnight, when the arc lamps are switched out.

The supply for lighting purposes was started on 5th ult., and the applications to date number 56, equivalent to 5,400 8-c.p. lamps. The method of charging will be 5d. per unit for the first 1,000 units, 4½d. per unit for the next 1,000 units, 4d. per unit for the next 1,000 units, 3½d. per unit for the next 1,000 units, and 3d. per unit for all units above 4,000 per term. For heating and power the prices are 2½d. per



Map of New Tramways proposed to be constructed under the Bury Corporation Bill of 1905.

Digitized by Google

unit for the first 1,000 units per term, with a reduction of ¼d. per unit for each successive 1,000 units up to 4,000, special terms being given to users taking more than 4,000 units.

The total cost of the lighting portion of the scheme is expected to be £37,000, while the cost of tramways will probably reach £42,000, which figures were stated by Dr. Kennedy, at the public luncheon, to be about £3,200 under the estimated cost. About £150 per week will be required to make the tramways completely self-supporting.

Mr. A. H. Burbridge, who was resident engineer for Messrs. Kennedy and Jenkin, the consulting engineers, has been appointed chief engineer and manager of the entire concern. Mr. Burbridge is a man of large experience, though only 30 years of age, and is a native of Somersetshire, having been educated at Windsor and Bristol Engineering College. He served his time, for four years, with Hawthorne, Leslie, and Co., of Newcastle-on-Tyne, and was in that firm's drawing office for three years. In 1900 and 1901 he had charge of the erection of the Motherwell electricity works. In 1904 he went to Kirkcaldy to take full charge of the electrical undertaking of that town.

The ceremony of starting the first car was carried out by Lord Howard de Walden. Before declaring the tramways system open and starting the gaily-decorated car which he occupied with a number of other prominent citizens, his lordship was presented with a silver-mounted motorman's controller with which to perform his office. Mr. Nelson, of Hurst, Nelson, and Co., made the presentation.

After the opening run over the track in six of the cars, the councillors and their friends adjourned to the George Hotel, Kilmarnock, where luncheon was served, Provost Hood, of Kilmarnock, being in the chair. Presentations were made by the chief contractors to Lord Howard de Walden, Provost Hood, and Bailie Wilson, the last-named being convener of the Electric Committee and a most enthusiastic and energetic worker for the scheme which has now been brought to such a successful consummation.

BURY CORPORATION TRAMWAYS.

Another important link in the chain of electric tramways is contemplated by the Corporation of Bury in a Bill deposited this session. The Corporation are seeking powers to connect their existing tramway system with the Bolton tramways; also to provide tramways in the urban districts of Tottington and Ramsbottom, connecting Greenmount, Holcombe Brook, Ramsbottom, Stubbins, Edenfield, and Shuttleworth with Bury. This latter tramway extends to the boundary of the borough of Rawtenstall. The diagram on opposite page will more fully explain the routes. The length of track is 20 miles. It might be added that the Bury Corporation have a system comprising 18 miles of track in full operation. The Corporation are also working a section of about half a mile in Whitefield belonging to Salford Corporation, so that Bury is in direct tram connection with Manchester and Salford. They will also work the Radcliffe tramways, consisting of 6½ miles of track, as soon as the construction is completed, and which is expected during the next few months. Radcliffe will then also be in communication with Manchester and Salford. Mr. Arthur W. Bradley, the borough engineer, is engineer for the present scheme, and he was engineer for and constructed the tramways now in operation.

INSTITUTION OF ELECTRICAL ENGINEERS.

At the ordinary general meeting on Dec. 8 the following were the candidates balloted for:

Member.—A. Clough, Newhaven, 14, Mersey-avenue, Aigburth, Liverpool.

Associate Members.—B. H. Lamb, care of Messrs. Thos. Cook and Son, Calcutta; C. R. Palairet, 100, Baron's Court-road, West Kensington; J. N. Stephens, 1, Devonshire-road, Palmer's Green, N.; W. H. Williams, 35A, Pembroke-square, Kensington.

Student.—A. J. Langhorne, Claverhouse, Upper Sydenham, S.E.

FORTHCOMING EVENTS.

FRIDAY, DEC. 16.

Institution of Mechanical Engineers. — At 8 p.m., "Heat Treatment Experiments with Chrome-Vanadium Steel," by Captain H. R. Sankey and Mr. J. Kent-Smith. Messrs. Seaton and Jude's paper on "Impact Tests on the Wrought Steels of Commerce," which was read at the last meeting, will be further discussed jointly with the above paper.

North-East Coast Institution of Engineers and Shipbuilders.—General meeting.

Institution of Electrical Engineers (Manchester Students' Section).—At 7.30 p.m., "The Working of Batteries under Reversible-Booster Control," by Mr. E. D. S. Shelmerdine.

Institution of Civil Engineers.—At 8 p.m., students' meeting, "Folkestone Harbour: Cylinder-Sinking at the Root of the Old Pier," by Mr. R. H. L. Pennell.

Tramways and Light Railways Association.—Visit to power houses of the Great Northern and City and the City and South London Railways. Meet at Moorgate-street Station at 2 p.m.

SATURDAY, DEC. 17.

Glasgow Technical College.—Anniversary dinner.

MONDAY, DEC. 19.

Faraday Society.—At 8 p.m., "The Electric Furnace: Its Origin, Transformation, and Applications (Part II.)," by Mr. A. Minet; "Electrolytic Analysis of Cobalt and Nickel," by Mr. F. Mollwo Perkin and Mr. W. C. Prebble; "The Electrolytic Preparation of Tin Paste," by Mr. F. Gelstharp; and "Note on the Electrolytic Recovery of Tin," by Mr. F. Gelstharp.

TUESDAY, DEC. 20.

Institution of Civil Engineers.—At 8 p.m., resumed discussion on Messrs. Wood-Hill and Pain's paper, "On the Construction of a Concrete Railway Viaduct."

Institution of Engineers and Shipbuilders in Scotland.—At 8 p.m., general meeting at Glasgow.

WEDNESDAY, DEC. 21.

Royal Meteorological Society.—At 7.30 p.m., discussion on Mr. F. J. Brodie's paper, "Decrease of Fog in London during Recent Years," and the following paper will be read: "The Study of the Minor Fluctuations of Atmospheric Pressure," by Dr. W. N. Shaw and Mr. W. H. Dines.

Jan. 13.—A lecture, entitled "Theory of Electricity and Magnetism," will be delivered by Mr. J. Swinburne to the students of the Institution of Civil Engineers.

Jan. 27.—The following papers will be read at the Physical Society: "Action of a Magnetic Field on the Discharge through a Gas," by Dr. R. S. Willows; "Action of Radium on the Electric Spark," by Dr. Willows and Mr. J. Peck; "The Slow Stretch in India-rubber, Glass, and Metal Wires when subjected to a Constant Pull," by Mr. J. Phillips; "Determination of Young's Modulus for Glass," by Mr. C. A. Bell; and "Some Methods for Studying the Viscosity of Solids," by Dr. Boris Weinberg.

PERSONAL.

Mr. John Henry Fooks Bale was on Wednesday appointed electrical engineer to the Battersea Borough Council at a commencing salary of £400. Mr. Bale has been resident electrical engineer, Mersey Railway, for the British Westinghouse Company since 1902. On emanating from the City of London College, Finsbury, and Owen's College, Manchester, he became a mechanical pupil at the Haslam Engine Works, Derby, 1887-1890, and subsequently an electrical pupil at Messrs. Immisch and Co.'s, London, 1890-1893. Mr. Bale was construction engineer and resident engineer and manager to the Brush Electrical Engineering Company, Limited, Loughborough, and Lynton Electric Light and Power Company, Limited, from 1893 to 1899, and chief assistant electrical engineer to the Manchester Corporation from 1899 to 1902. There were 108 applications. There were also 131 applications for the appointment of a shift engineer at a salary of £104 per annum, and Mr. J. Galbraith-Westlake, of Peterborough, has been appointed.

The Kirkcaldy Town Council have increased the salary of Mr. O. F. Francis, burgh electrical engineer, from £250 to £300 per annum.

Mr. J. E. Teasdel, deputy electrical engineer under the Cardiff Corporation, has been the recipient of a gold watch and chain, case of cutlery, and a cigar-case from the employés of the electric light and tramways department on the occasion of his leaving Cardiff to take up the post of chief engineer and manager of the electric light and tramways of Pontypridd Urban District Council.

New Publications.—"Elements of the Differential and Integral Calculus," by W. A. Granville. (New York: Ginn and Co.; London: F. J. Mathieson. 10s. 6d.).—"Petrol Motors and Motorcars," by T. H. White. (London: Longmans, Green, and Co. 4s. 6d.).—"The Electrical Transmission of Energy," by A. V. Abbott. (London: Crosby Lockwood and Son. 30s.).

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

"SHOWING A FACE."

This is an American expression, as explained by Sir W. White at the jubilee dinner of the Society of Engineers on Wednesday last. Purely professional topics may be extremely pressing and interesting, but an occasional aside or burst hurts no man; on the contrary, frequently does good. The Society of Engineers is not an electrical society, although its *Transactions* contain a good many papers on electrical subjects, yet it deserves a good word here because of its general work and because of its age. Third in age among the engineering societies — the Institution of Civil Engineers and the Institution of Mechanical Engineers being older—it has for fifty years quietly and unostentatiously done good work. It was happily put by the president (Mr. D. B. Butler) that the society's influence for good was especially great among younger men. In the two older institutions the numbers were larger, the critics of the widest experience, so that young men felt diffident in expressing opinions. The Society of Engineers thus forms a training ground where young men can move freely, express their views, and more readily gain a hearing. The beginner often has something good to say, but finds a difficulty in saying it and ease of expression and the logical putting of the argument, which come, like most things, by constant practice. Fifty years ago the Society of Engineers was founded at Putney, and called the Putney Club, and in 1857 the club became the society, and the meetings henceforth were held in London. Sir W. White, in an exceedingly interesting speech, pointed out that an older society, called the Society of Engineers, was founded in 1771, and was still in existence, but under another name — "The Smeaton Society"—in honour of Smeaton, the builder of Eddystone Lighthouse. At the close of the year 1855 the Society of Engineers numbered twenty-five members, in 1857 these had increased to fifty-four, while in this—the jubilee year—the roll numbers over five hundred. We think young men should consider well the claims and the advantages of the society, and support it in still greater numbers. Among the advantages — and by no means the least — is the "showing a face"—that is, meeting fellow professionals, hearing criticism, exchanging opinions, and, above all, establishing friendly intercourse with the members of the profession who are growing up and doing business all round. The young men of to-day—learners, it may be—are the workers of to-morrow, the men who will be called upon to engineer the world. Fifty years ago a large part of the world's surface was a *terra incognito*. Intercommunication was a difficulty, the interchange of letters and messages with the Antipodes a question of months. Now we are linked by cables, the ocean is traversed by ships of a size and speed then undreamt of. Monetary proceedings of huge magnitude are transacted by means of a cablegram, and on every hand progress has been so rapid that the gain to the world is incalculable. Progress is surely not at an end. It may even proceed at a greater rate in the near future than it has done in the immediate past. We talk about an electrical era. Why, electrical engineering is a thing of the past quarter of a century, and what it will be at the end of another quarter of a century no man knows. Will horses be then kept in museums; will steam under the conditions now known be a thing of the past; shall we have yoked the ether and able to hold the reins? We know not; but one thing we do know. It is that the possibilities in the hands of the younger men are enormous—unprecedented in the history of the world. It is they who must carry on the work of progress. They dare where the older, and in a way more experienced, would

Digitized by Google

never venture. They, with youth and energy backed by knowledge and ability, are those who will work among great things, and to qualify for that work must "show a face" everywhere and on all occasions. Would that words could act as a trumpet-call, and waken up the young men. England behind? Rubbish! We may be sleepy, but all that is necessary to place us in the forefront of nations is for the younger men to put in their energy, and let it be, when necessary, qualified by the experience of their elders.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

PROPOSED BENEVOLENT FUND.

SIR,—It having been pointed out in many quarters that the electrical industry, although very wide-reaching and giving employment and occupation to many thousands of individuals in all grades of life, has in connection with it no means of supporting any of those unfortunate members of it who fall into temporary or permanent need, an influential committee of gentlemen actively connected with various branches of electrical work has been constituted to organise a benevolent fund for the industry.

This committee has authorised me to announce to you that insufficient time has elapsed to prepare a full scheme of operation, but that as we are approaching the Christmas season, when doubtless many connected both directly and indirectly with the industry are giving gifts in kind and cash, to ask you to make a preliminary notice in your esteemed journal so that they may earmark or retain some important percentage of these gifts for the fund.

As soon as a sufficient sum is available, this fund will eventually be used for the purpose of providing pensions and donations for deserving cases in the electrical industry, voted for by the subscribers.

Further details will shortly be announced, but in the interval the organisation is being rapidly proceeded with.—Yours, etc. JUSTUS ECK.

[We publish the above, as requested by Mr. Justus Eck, but unless the effort is being made in connection with the benevolent fund of the Institution of Electrical Engineers we should not be inclined to give it our support. We have felt for a long time that the benevolent fund of the Institution is not receiving the support it deserves, and that it really should have the consideration of the Council before the scheme for providing a separate building for the Institution's work. In the severe competition nowadays the early pioneers of the electrical industry are apt to fall behind in the race, and it is only right that the profession as a whole should assist in cases of this kind. The benevolent fund of the Institution of Civil Engineers does a splendid work in this way, and it is free from one point which is unavoidable in Mr. Justus Eck's proposal—*i.e.*, if the deserving cases are to be voted on by the subscribers, the assistance can only be given after extended publicity. In the case of the Civil Engineers' Benevolent Fund only two, we believe, of the committee actually know the names of those receiving assistance. If this is so, there is more chance of help being given where most deserved than is possible when there is publicity both of the application and of the award. We do not know how far Mr. Eck proposes to deal with workmen connected with the industry, but these, we think, have a benevolent fund in their trade society.—ED. *E. E.*]

RUNNING POWERS—COMPULSORY OR OTHERWISE.

The following interesting letters on the above subject have been received since we published our last issue dealing fully with the matter. The experience of the writers lends great weight to their opinions.

Rotherham, Dec. 13, 1904.

Dear Sir,—It is a difficult matter, indeed, to express an opinion as to the desirability of intercommunication between tramway systems, and particularly with regard to the commercial possibilities of compulsory interchange of traffic and the best method of dividing the receipts and working expenses from the through-going traffic. I am, however, of opinion that it is wise where authorities can enter into agreements to have intercommunication, it is desirable in the interests of towns separated by very short distances, and in some cases where there is no actual distinction except what is recognised by the various rating authorities.

We are on the point of arranging with Sheffield to run through from Rotherham, and *vice versâ*. Unquestionably it will be a gain to both towns. It will facilitate travelling and induce greater numbers to use the trams, although the period of waiting at our terminus is comparatively short, yet, short as it is, those who are in the habit of using the trams are constantly grumbling because of the necessity of changing from one car to another. The method of dividing the receipts will have to be regulated according to the traffic in each particular town. For instance, in some towns it might be found that the traffic in each town will be about equal, and I am of opinion that the easier way of dealing with the receipts is to let each authority take the receipts in its own area, giving the conductors tickets belonging to both authorities. The working expenses can be dealt with in almost the same way—*i.e.*, each undertaking bearing its own expenses in its own area, unless, of course, the distance in one area is greater than the other, and in that case the agreement would have to be made on the basis of so much per car mile run.

D. L. WINTER,
Chairman of the Rotherham Tramway Committee.

Rotherham, Dec. 8, 1904.

Dear Sir,—I am in receipt of yours of the 29th ult. *re* the question of intercommunication between tramway systems. The Newcastle case, as you pointed out, has been more in evidence of late, and I am pleased to see that this is being amicably settled. I am certainly of the opinion that where intercommunication between tramway systems is practicable, it is most desirable and in the interest of the public that a mutual arrangement for interchange of traffic should be come to. As to terms, I think that this is a question that could be settled with very little difficulty by the authorities interested.

With regard to the latter part of your letter *re* the carrying of parcels and goods, this is no new thing, having been done for some years on several systems, and to my knowledge adds very considerably to the revenue, and I am sure it is worthy of most careful consideration by all tramways committees.

I regret that I have not had time to go further into the matter, but trust these few remarks will be of service to you.—Yours faithfully, W. GRANT,
General Manager, Rotherham Tramways.

Liscard, Cheshire, Dec. 8, 1904.

Dear Sir,—Replying to your enquiry, which I regret has not had earlier attention, the question of running powers over electric tramways is one that is bound to be much in evidence in the future, and personally I am in favour of providing the amplest facilities for intercommunication between neighbouring communities, so that where a mutual working arrangement cannot be entered into between two or more undertakings, and it can be shown there is a public demand for tramway accommodation, I think that running powers should be conceded, subject to the payment to the owning authority of an adequate amount for wear and tear, and an equitable proportion of the earnings on its track.—Yours faithfully, R. R. GREENE,
General Manager, Wallasey Council Tramways.

Bournemouth.—A memorial has been sent to the Corporation for an extension from Westbourne to Sandbanks.

BRADFORD'S BURNOUT.

Thursday, Dec. 8, will be remembered by those connected with (or connected to) the Bradford electricity supply for some considerable time as a day of disaster and vexation, possibly with the usual Athanasian accompaniment.

The shadow of the trouble had been hanging over the heads of those responsible for some little time previously, as the recent report of Mr. Blackman's to the Electricity Committee foreboded. This report stated that the sheathing of some of the cables had been eaten away, and that a considerable amount was known to be on the point of breaking down. That this was a correct estimate may be judged by the fact that a short-circuit occurred upon the negative side of the system in the morning at six o'clock, developing into a heavy short across the outers 10 minutes later, and upon investigation the fault was located to the feeder laid across the iron bridge in School-street. The feeder was disconnected at both ends, but a heavy fault still remained. The pavement upon the railway bridge was opened up, when it was found that the arcing had burnt a hole in the iron plates forming the bottom of the bridge. The cable was cut upon each side of this, and tested bad in both directions.

At 8.30 a.m. the pavement opposite the Midland Station, about a quarter-mile distant from the bridge, was displaced by an explosion, and the ground was immediately opened up to expose the cables, which at this point are laid in two parallel brick and stone culverts, which contain the cables supplying current to the four most important feeding points in the centre of the town. While this work was proceeding, violent explosions occurred, and the pavement was displaced at other points in the immediate vicinity. The explosions became so serious that at 10 o'clock the works were shut down in order that the faulty cables might be cut clear.

There are at each feeding point three pavement boxes arranged side by side, and the links in all except the centre boxes were removed at the four feeding points and at the works, but the explosions continued after the current was cut off with increasing violence, so that it was not considered advisable to commence running again until the ground had been opened up and the culverts ventilated in places by the removal of the cover stones, which are 6in. thick, and consequently heavy to handle.

Observation at this time showed that nearly all the 15 cables in the two culverts were burnt asunder. The works were started up again at mid-day, when smoke commenced to re-issue from the ground, the mains being at the time fed by 1,800 kw. of plant across the outers, and 320 kw. of steam balancers on each side. The ground was accordingly opened up below the bottom of the culverts, and short lengths of armoured cable, which, by the way, no one upon the job knew were located there, pulled out in a very heated condition. It was difficult at the moment to account for the cable being alive, as the whole of the cables had, so far as could be ascertained, been disconnected at both ends upon the positive and negative poles. The bottom of the culvert, which also consisted of stone slabs 6in. thick, was removed for some yards, and arcs exposed, which were, however, kept down by re-covering them with earth. The works and feeding-point boxes were visited to confirm that all the links in the outside boxes and at the works had been removed. This proving to be the case, and as the arcing continued with unabated vigour in close proximity to a large gas-main, the works were shut down a second time at 2.30, as the feeders remaining were not in any event nearly adequate to carry the evening load. It was subsequently found that pieces were fused out of the gas-main which was not cut off, and it is therefore probable that the damage would have assumed very serious proportions had the arcing continued.

The whole of the cables upon each side of the fault were now cut, and every available man was set trimming back the ends, as it was necessary to test the cables to ascertain which were useable, as they had been very considerably heated carrying the heavy currents to the faults, and the terminal points of the individual cables in each direction were unknown, owing to the cables having been mixed in the culvert.

While this work was proceeding new cable was got on to the job and pulled in to bridge the gap, which was 160 yards in length. Several of the cables in different parts of the town were found to have dead earths upon them, which so reduced the capacity of the mains between the fault and the feeding points that the current could not be reinstated until such time at night as the load fell to the capacity of the available mains. The supply of practically the whole of the town was reinstated at midnight, but while the main fault was being dealt with another developed in quite another part of the town, and this was taken in hand and the supply recommenced here soon after six next morning. During the night the faults upon the more important of the defective cables were located, and the following day additional temporary cables were got in to augment those bridging the gap caused by the destroyed cables.

The cables that were the cause of the mishap, and those burnt out thereby, were laid between 8½ and 16 years ago, and were burnt through at many places at old-fashioned, cast-iron, straight-through joint-boxes, fitted with rubber glands, the cables having lead sheaths and hygroscopic insulation. The Bradford system of mains has until the last few months consisted wholly of single-core cables, and there are no fuses upon these.

The mystery of the live cables beneath the culverts was cleared up in tracing the cables out, and found to be caused by a set of three single-pole disconnecting boxes being arranged with the negative between the positive and neutral instead of the neutral box being in the centre, as in all other parts of the town.

The trouble is attributed to stray currents upon the cable sheaths causing a fault at the point where a cable entered a rubber gland joint-box, and thus raising the potential of the lead sheaths (these not being electrically connected across the boxes), and the moral is obvious.

Considerable inconvenience was caused by the complete shut down of the thousand odd motors in the town. Candles were quickly at famine prices, and finally became unobtainable. A committee meeting at the town hall was illumined by candles stuck in whisky bottles, which, strange to say, were found on the premises. When at midnight the current was put on from the works, the unusual spectacle of business establishments fully lit up and with shafting at work was to be seen. This was due to switches having been left on, and a number of policemen were detailed to drag unfortunate shopkeepers from their beds in the suburbs to come down and switch off.

THE MEASUREMENT OF VACUUM.*

BY C. TURNBULL.

The invention of the steam-turbine has given us an electric generator taking up little space even for enormous outputs. We are also able to obtain single boilers which will give us as much as 40,000lb. of water in an hour in an economical manner, although taking up small floor space. But while many of the problems of other days are being solved, the greater problem still confronts us—namely, that the price for electrical energy has gone down to limits that were almost undreamt of, and it is likely to go down still further. We must therefore look to the saving of at present neglected losses to pay our way in the future. Given large and efficient engines and boilers in the station, one of the chief problems will be to move very large quantities of coal, oxygen, and condensing water in the most economical manner. Indeed, I have no doubt that we will soon see the same attention given to instruments showing the composition and temperature of flue gases, the amount and temperature of condensing water, and to the actual vacuum at the engine exhaust, with a view to the regulation of the results in a proper manner, that is now given to the switchboard instruments.

* Paper read before the Newcastle Section of the Institution of Electrical Engineers.

Digitized by Google

To-night I would particularly direct your attention to the measurement of vacuum. While this is becoming one of the most important things in the whole station, its measurement at present is obtained in a most unsatisfactory and indirect manner. The vacuum gauge in common use measures the difference between the condenser pressure and the atmospheric pressure. It is, therefore, necessary to read the barometer as well as the vacuum gauge to get at the true result. Thus with a vacuum gauge at 25in. and the barometer at 30in., the actual pressure of the condenser

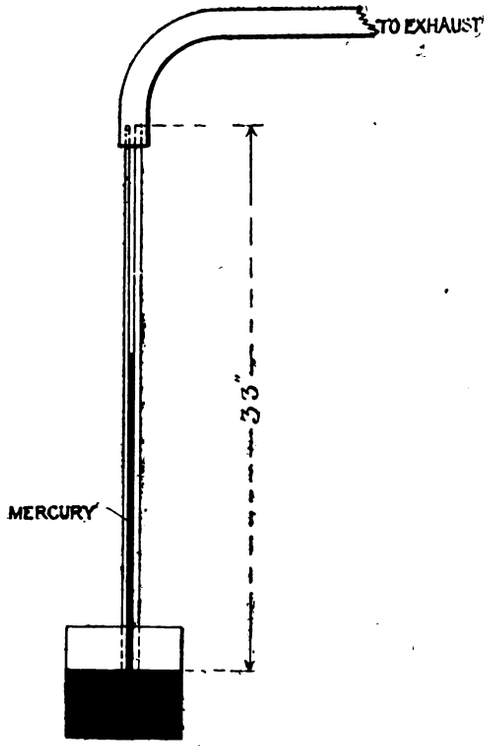

FIG. 1.

is 5in., and this 5in. is the only quantity that really concerns us. (The term "percentage of vacuum" which is sometimes used is quite wrong.) Unfortunately, this fact seems to have been covered up a good deal. A high barometer helps to make a high reading on the vacuum gauge, and people sometimes seem to like it accordingly, yet the increased atmospheric pressure probably decreases the actual vacuum. The lower the barometer is, the better will be the actual vacuum, although the vacuum gauge will

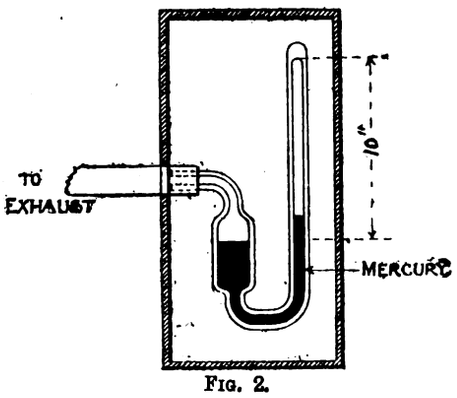

FIG. 2.

show a worse result. What we require, then, is an instrument which will fulfil the following requirements: (1) it must show the actual pressure in the condenser quite independently of the pressure of the atmosphere; (2) it must be quite accurate in its readings, and not liable to go wrong.

The first requirement would be met by an ordinary Bourdon gauge with an *exhausted tube* (or a similar arrangement to that used in the aneroid barometer), but with the *case* of the instrument connected to the condenser. This will measure the actual pressure at the exhaust, quite independently of the pressure of the atmosphere. Another and perhaps better way is to make use of the ordinary mercury barometer, only it must be connected up properly. As ordinarily used (Fig. 1) the mercury column balances the difference between the condenser pressure and that of the atmosphere. If we connect up as in Fig. 2, the mercury column will show simply the actual pressure in the condenser, and quite accurately. When the mercury rises 4in. in the tube, it means just that there is a pressure in the condenser which has an effect upon the back of the piston of a reciprocating engine as if the piston were lifting a layer of mercury 4in. deep. I think that this concrete idea helps us to understand the reality of the stuff left in a 26in. vacuum, and how it is that good work may be got out of this stuff if it is allowed to flow into a still lower pressure. For most purposes with the Fig. 2 instrument, a 10in. tube is quite long enough, for this will show a vacuum as low as 20in. The instrument can therefore be made in a neat and cheap form. The idea is not new, of course, but so far as I know it has not come into common use. Whether or no it would be better to speak of a 29in. vacuum as being a 1in. back pressure, time alone will show.

Position of Gauge.—It is to be noted that the reading of any vacuum gauge is materially altered by its position. If it be placed low down, then water will collect in the tube leading to it, and the weight of the column of water will affect the reading. Probably this fact often accounts for the difference of reading between the gauge on the engine exhaust pipe and the gauge on the condenser, as much as the drop of pressure between the two due to loss in the connecting pipes.

Seeing the enormous importance of good vacuum with large turbines, I have thought that the subject would prove worthy of your interest to-night

THE USE OF IRON IN ALTERNATE-CURRENT INSTRUMENTS.*

BY W. E. SUMPNER, D.SC., MEMBER.

(Concluded from page 853.)

APPENDIX.

Note I.—The Action of a Rotating Magnetic Field on a Coil conveying an Alternating Current, and free to rotate about the same axis as the field.

Assume the axis of rotation perpendicular to the plane of the paper and represented by O in Fig. 10. Let the rotating field be of constant strength, F, and of uniform angular velocity, p. Let its position be O F_0 initially, and be O F at time t, where $\theta = pt$ is the angle $F\hat{O}F_0$. Let the plane of the coil be represented by O C inclined at angle

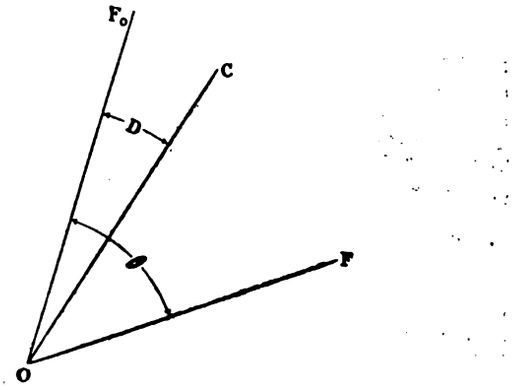

FIG. 10.

D to O F_0. Suppose the current in the coil follows the sine law, and that its value at any moment is

$$A_0 \sin (pt - \phi)$$

where ϕ is the phase angle to be measured, then the torque tending to move the coil is at every instant proportional to

$$A_0 F \sin (pt - \phi) \cos (pt - D).$$

The mean value of this will be zero when

$$D = \phi,$$

* Inaugural address of the Chairman, delivered before the Birmingham Local Section of the Institution of Electrical Engineers.

Digitized by Google

or the angular deflection, D, of a pointer attached to the coil will directly measure the phase angle ϕ whatever the frequency of the current. If ϕ is greater than D the coil will move so as to increase D, and *vice versâ*, the turning moment reversing sign with $D - \phi$. It will be readily seen that the turning moment is greatest when D and ϕ differ by 90deg., and that there is an unstable position of equilibrium when these quantities differ by 180deg.

The rotating field will tend to induce a current in the coil as in an induction motor, and there will in consequence be a tendency for it to rotate with the field. This can be made quite negligible by the use of resistances in series with the coil. The more inductive these resistances are the less will be the effect. If the current in the coil is produced, as it would be in practice, by a current transformer, a tendency of this kind would have no effect on the current through the coil, but only on the voltage absorbed by the primary.

If the current does not follow the sine law there will be no direct proportionality between the deflection, D, and the effective angle of lag of the current. If, however, the rotating field be uniform in strength and angular velocity, D will depend upon and be a measure of the time elapsing between the instant at which the field is directed along OF_0, and the instant at which the current passes through its zero value, but D must be measured from some zero position not necessarily coinciding with OF_0. The calibration of the instrument as a power-factor indicator will to a slight extent be dependent on the wave-form of the current, for if F is constant in magnitude and angular velocity, while the current, A, through the coil has some special wave-form, the torque on the coil is proportional to

$$A \cos (pt - D),$$

and its average value will vanish for a particular relative position of the waves representing the current A and the sine function $\cos (pt - D)$, supposing these waves plotted to a time base. If the wave-form of A remains constant, but its phase (as represented by the instant of reversal) varies, the displacement of the wave A will be proportional to the time representing the phase, while the displacement of the wave $\cos (pt - D)$ will be proportional to D, hence for different phases of A the equilibrium value of D will be a direct measure of this time or phase.

If F is neither uniform in angular velocity nor constant in magnitude, the effect becomes more complicated. The torque is then measured by the average value of

$$A F \cos (\theta - D),$$

where $$F = F_0 + f, \text{ and } \theta = pt + \delta.$$

F_0 is the average strength of the rotating field, and p the average value of its angular velocity. A, f, and δ are alternating periodic functions of the time. D is then no longer proportional to the time representing the phase of A, but is still solely determined by this time for given wave-forms of A, f, and δ.

Note II.—Wattmeter Errors.

If owing to self-induction in the pressure coil the current in it lags by an angle θ behind the voltage causing it, the wattmeter will read

$$V A \cos \theta \cos (\phi - \theta), \text{ instead of } V A \cos \phi,$$

where $\cos \phi$ is the power factor of the load, and ϕ is positive for lagging currents and negative for leading ones. The factor $\cos \theta$ can be considered unity for the small angles of θ at all likely to occur. Even if θ is 1deg, $\cos \theta = 0{\cdot}99985$. This factor is, moreover, independent of the phase of the load, and is, therefore, allowed for in the calibration of the instrument. Its variation with frequency is utterly negligible.

We can regard the small angle θ as a small decrement of ϕ, so that if the true watts, W, are given by

$$W = V A \cos \phi,$$

we have for the error δW,

$$\delta W = -\theta \frac{d W}{d \phi} = \theta V A \sin \phi,$$

or,
$$\frac{\delta W}{W} = \theta \tan \phi, \text{ and } \frac{\delta W}{V A} = \theta \sin \phi.$$

In these equations, of course, θ must be in radians (1deg. = 0 01745), so that $\theta \tan \phi$ represents the error in reading as compared with the true power in watts, while $\theta \sin \phi$ is the ratio the error in reading bears to the volt-amperes. These errors are worked out in Table I. for an angle of 1deg. For small angles the errors are proportional to θ. Whether these errors produce an appreciable effect on the instrument reading depends very much on the meaning in watts of the full deflection of the instrument. If this denotes V A numerically, the error as a reading may not be easily detected for lower power factors, but if it denotes V A $\cos \phi$, or W, the error may be large.

The error increases with the phase difference ϕ between volts and amperes. In the measurement of power on three-phase mains by the two-wattmeter method, there is always a phase difference of 30deg. or more between the currents in the two coils of one of the instruments, and it seems natural to expect appreciable errors in the masurement when the mains carry lagging currents. But on examination it will be found that the error is not greater than would be the case on single-phase mains carrying currents of the same power factor. For if the instruments are alike, the effect of a small lag θ in the pressure coils is the same as slightly diminishing ϕ. The two wattmeters read respectively

$$W_1 = A V \cos (30 + \overline{\phi - \theta})$$

and
$$W_2 = A V \cos (30 - \overline{\phi - \theta}),$$

where V is the voltage between the mains, and A is the line current, assuming balanced loads.

So that the watts read are given by

$$W_1 + W_2 = 2 A V \cos 30 \cos (\phi - \theta),$$

and the true watts, W, are obtained from this by putting $\theta = 0$. Hence as before, regarding θ as a small decrement of ϕ, we have, if δW is the error in the measurement,

$$\frac{\delta W}{W} = \theta \tan \phi.$$

Note III.—On Wattmeters having Iron-Cored Electromagnets.

Suppose an instrument such as is illustrated in Figs. 6 to 8 have its electromagnet excited by a coil of n_1 turns and resistance r, by means of a current A_m produced by voltage V_1. Let N be the total flux through the coil, the induction density in every part of the air-gap being assumed proportional to N. We have

$$V_1 = r A_m + n_1 \frac{d N}{dt} \quad . \quad . \quad . \quad . \quad (1)$$

Let the load current, A, be passed through the primary of an air-core transformer, the secondary of which is connected, through a considerable non-inductive resistance, R, with the moving coil of the instrument. Assume the current, c, produced in the secondary winding is insufficient to alter the magnetic effect of A. We then have

$$c = \frac{k}{R} \frac{d A}{dt} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where k is some constant. The torque exerted on the moving coil for any given deflection will be proportional to

$$\int_0^T c N \, dt,$$

where T is the periodic time. This quantity is proportional to

$$\int_0^T N \frac{d A}{dt} dt.$$

But since N and A are periodic functions having the same period, T, this integral is easily shown to be the same numerically as

$$\int_0^T A \frac{d N}{dt} dt.$$

whence by (1) it is proportional to

$$\int_0^T A (V_1 - r A_m) \, dt.$$

Assuming that the vector representing the copper drop,

Digitized by Google

$r A_m$, is negligible in comparison with that representing V_1, it will be seen that the deflection of the instrument is a measure of

$$\int_o^T A V_1 \, dt,$$

or of the watts, if V_1 is the voltage across the mains. This result will be true whatever the wave-form or frequency, whatever the nature of the iron forming the core of the electromagnet, and whatever the phase difference between V_1 and A, provided the copper drop is negligible, and the transformer current, c, varies as the rate of change of A.

Suppose the self induced magnetic voltage is denoted by V_m, where

$$V_m = n_1 \frac{dN}{dt}, \text{ and } V_1 = r A_m + V_m,$$

the deflection of the instrument measures the mean value of the product $V_m A$ in all cases. Suppose the coil of the electromagnet, instead of being shunted directly to the mains, forms the load of the secondary of an instrument transformer, the primary of which is shunted across the mains at voltage V. The average product of V A then represents the watts to be measured, while the reading of the instrument is a measure of the mean value of $V_m A$.

If Fig. 11 represents the vector diagram of the voltages and currents considered, and if θ_1 and θ_2 represent respectively the phase differences between V_1 and V, and between V_1 and V_m, the error in the wattmeter mainly depends

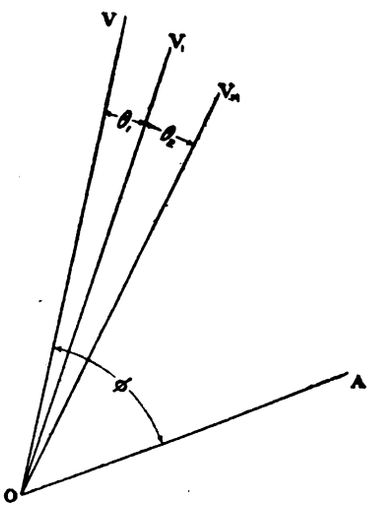

FIG. 11.

upon the values of these phase differences, θ_1 and θ_2. For the ratio of the lengths of the vectors V_m and V is independent of ϕ, the phase of the load current A in reference to V, and varies only inappreciably with frequency, or for different values of V. If θ is the excess of the angle separating V from A, over the angle separating V_m from A, the error of the wattmeter follows the same law as that given in Note II., and we have for small values of θ,

$$\frac{\delta W}{W} = \theta \tan \phi.$$

The value of θ must be well within 1deg if the wattmeter is to work satisfactorily on circuits of different power factor. θ is the resultant phase error due to (1) the phase difference between V_1 and V_m; (2) the phase difference between the primary and secondary voltage of a pressure transformer if used with the magnetising coil; and (3) any difference between a right angle and the actual phase difference of the currents c and A.

It is to be noted that the inductive effect of the alternating field does not tend to turn the moving coil. The field flux, N_1, enclosed by the latter varies with the position of the coil, but, for a given position, is always proportional to the total flux, N, produced by the alternating electromagnet. The induced E.M.F. is proportional to the rate of change of N, so that with non-inductive resistances in series with the coil the current produced by this E.M.F. is proportional to, and in phase with, the rate of change of N. The field in which the coil is placed is measured by N, so that the torque on the coil due to this induced current is proportional to

$$N \frac{d \cdot N}{dt},$$

the average value of which is zero for all periodic functions.

If it can be shown that the angle between V_1 and V_m introduced by the copper drop in the magnetising coil is no larger than the phase differences caused by the use of current and voltage transformers with wattmeters, it necessarily follows that the use of iron-cored electromagnets in wattmeters need introduce no greater error into the measurement of power than such transformers actually do in practice, while the greater sensitiveness and range of an instrument constructed in this way are obvious advantages.

TRADE NOTICES AND NOVELTIES.

Electrical Instruments.

During the last two years Messrs. Crompton and Co., Limited, have been engaged in working out a system of manufacturing electrical instruments of the moving-coil type for direct currents in such a way that they can be easily verified and adjusted by the user. The practical results of this labour are set forth in a pamphlet recently published by the firm. In this pamphlet the details of the construction adopted are clearly described and illustrated. Every indicating instrument is, we are told, either a milliampere-meter reading to 15 milliamperes, or a milli-voltmeter reading to 75 milli-volts. The large currents or pressures they are used to indicate are not required for their calibration, for which a Leclanché dry cell or a small accumulator is sufficient. The method of testing them, and of making any small corrections that may be found necessary, is explained on pp. 9 and 10 of the pamphlet, a copy of which any reader interested could not do better than obtain.

"Bifluid" Tachometers.

A new type of speed indicator is described in a list recently issued by Messrs. W. E. Moulsdale and Co., 24 Chapel-street, Liverpool. The "Bifluid" tachometer, as it is called, is a patented instrument for measuring speed of rotation or of progressive motion by utilising the difference of effect exercised by centrifugal force on two fluids of widely different specific gravity, enclosed in a tube and specially-constructed reservoir. The instrument may be mounted direct upon any vertical revolving part, or driven by pulley and belt from any rotating part of the machine. It has no springs, levers, or pendulums, but acts like a thermometer or a barometer, indicating on a scale by the height of the fluid in the tube the speed of the motor or machine at any instant. The scale may be graduated to show miles per hour, feet per second, revolutions per minute, knots per hour, or any other desired combination.

Fourteen-Day Recording Instruments.

We note that Messrs. J. H. Holmes and Co., Newcastle-on-Tyne, are making recording voltmeters and ammeters which will run for a fortnight without rewinding or reinking. In other words, two of the chief difficulties peculiar to the design of this class of apparatus—that of driving a continuous band of paper and keeping up a supply of ink for a lengthened period without constant attention—have been successfully overcome in these instruments; the former by the use of a serrated driving wheel acting on the centre of the paper band, and the latter by a special form of pen capable of carrying a large supply of ink, and moving across the paper in a straight line instead of describing an arc of a circle. The paper roll is rewound on a spool after it has passed beneath the pen. The electrical movement consists of two solenoids, into which are drawn soft-iron cores attached to a beam on the spindle of the pen lever. The pull is exerted against a phosphor-bronze spring, and owing to the special form of solenoids and construction of other parts, a practically equal scale is produced, while hysteresis is reduced to a negligible quantity. The movement of the cores within the solenoids gives a strong damping effect, so much so that the system is more dead-beat than a moving-coil movement under similar conditions. For recording ammeters of 40 amperes and upwards a moving-coil system is, however, used in place of this solenoid movement, and outside shunts with lengths of flexible connectors are supplied. These recording ammeters and voltmeters are made in two types, respectively for mounting on switchboards and portable use. The portable type voltmeters have the resistances self-contained up to 300 volts; above that voltage separate resistance boxes are added.

Catalogues, etc.

DICK-KERR PLANT.—From Messrs. Dick, Kerr, and Co., Limited, of Abchurch-yard, Cannon-street, London, E.C., Preston, and Kilmarnock, come two publications—one a revised edition of their direct-current generator book and the second a volume describing alternating current machinery of the firm's manufacture. Either is well worthy of a place on any electrical engineer's bookshelf. In fact, we have never seen better productions of their kind, the illustrations being especially fine. The first-mentioned describes the various parts and the process of manufacture of a Preston standard-type continuous-current generator, while the principal features of Dick-Kerr three-phase generators and sub-station plant are set forth in book No. 2. The construction of these latter machines is based on the very latest developments in the design of polyphase plant. Some useful line drawings are given, in addition to a number

Digitized by Google

of splendid half-tone illustrations, and the descriptive matter is lucid in style. If the demand for these books bears a fair proportion to their merits, no doubt the current editions will soon be O.P. We must, indeed, congratulate Messrs. Dick, Kerr and Co., Limited, upon the general excellence of their latest publications.

FEED-WATER HEATERS, ETC.—Erith's Engineering Company, 70, Gracechurch-street, London, have sent us a copy of their catalogue, No. 153, dealing with "Cochrane" feed-water heaters and purifiers, of which they are the sole makers. These heaters are supplied for capacities ranging from 150 to 30,000 gallons per hour, and plants representing a very large total output have already been installed. In the same catalogue is described the firm's automatic hot process purifier. This is a water heater and softener combined, used for the chemical treatment of hard water. The purification is accomplished partly by the mechanical action of the heat of the exhaust steam, which drives off the liberated gases through a vent to the atmosphere, and partly by the use of a single inexpensive chemical reagent—viz., ordinary soda ash.

"EDISWAN" FITTINGS.—In issuing a second edition, the Edison and Swan United Electric Light Company, Limited, 36 and 37, Queen-street, Cheapside, E.C., have taken the opportunity to revise and enlarge their catalogue (Section II.) of ship, factory, and colliery fittings, etc. They are now listing a large size colliery fitting, with cast-iron painted reflector and well glass, to take up to five 32-c.p. lamps. We note, further, that a large assortment of all-porcelain fittings, cheap factory fittings, and street lamp fittings have been added; also two pages of traction fittings for the interiors of tramcars.

"HOLMES-PAGE" SWITCHES.—The advantages of "Holmes-Page" patent quick-break chopper-type switches are described in one of the catalogues recently issued by Messrs. J. H. Holmes and Co., Newcastle-on-Tyne, the makers. Several useful types are illustrated, among them being single, double, and triple pole switches in cast-iron boxes, designed to meet the requirements of the various fire offices, electricity supply companies, and municipal authorities. These switches, it may be added, are of particularly neat appearance.

EXCESS INDICATORS AND AUTOMATIC LIFT CONTROLLERS.—From Messrs. Monté Callow and Co., 6, Ludgate-broadway, E.C., we have recently received two leaflets, one of which describes excess indicators (Atkinson's patent). These indicators have been designed, we are told, to meet the requirements for an instrument to record the fact of an excess current having passed through electrical apparatus, such as motors, transformers, etc., for more than a short period of time. They work on the well-known principle of the Atkinson demand indicator, and are made in four types. The second leaflet deals with automatic reversing starters, suitable for lifts working on direct, alternating, or polyphase currents. In these starters the resistance cannot be cut out of circuit when the motor is so overloaded that it is unable to start.

WEST HAM CORPORATION TRAMWAYS.

Herewith we give abstracts of the revenue account and balance-sheet of the West Ham Corporation tramways for the half-year ended Sept. 30, 1904. The capital expenditure to that date amounted to £196,538.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Electric cars—traffic expenses	8,809	0	7
General expenses, salaries of staff, etc.	2,032	14	7
Repairs and maintenance of permanent way	1,422	5	5
Power expenses—purchase of current	3,324	1	0
Proportion of cost of temporary buildings	1,000	0	0
Repairs and maintenance of horse cars	762	8	1
Total amount of working expenses	17,350	9	8
Balance carried to net revenue account	13,397	11	6
	£30,748	1	2

Cr. Income.	£	s.	d.
Traffic revenue—electric cars	27,259	15	9
Advertising rights on cars	488	5	5
Traffic and sundry revenue from horse cars	3,000	0	0
	£30,748	1	2

BALANCE-SHEET.

Dr. Liabilities.	£	s.	d.
West Ham Corporation stock	289,604	0	0
Sinking fund	2,162	19	7
Sundry creditors	831	1	5
Reserve or renewals fund	3,016	7	9
	£295,614	8	9

Cr. Assets	£	s.	d.
Cost of existing works, etc.	196,538	5	3
Expenses of issue and discount of Corporation stock	41,350	11	10
Cash and investments—consolidated loans fund	2,162	19	7
Cash in bankers' hands	49,935	15	3
Stores on hand	413	6	8

NOTES ON PERMANENT WAY FOR TRAMWAYS.*

BY A. N. CONNETT, M.I.C.E. (MEMBER OF COUNCIL).

(Concluded from page 845.)

Theoretically, the flange pressure to overcome centre or side-plate friction on bogie trucks only takes place on entering and leaving the curve, assuming that this is not compounded. The trucks not being absolutely rigid, there is some "give" in them, and, consequently, flange pressure from this cause will exist all through the curve, though, of course, to a much greater degree at the two ends. To sum up, one cannot assume a minimum rail and flange wear with bogie trucks, especially of the side-bearing maximum traction type. Previous to the introduction of the standard types, most of the curve rails had vertical sides to the lip or guard. Consequently the wear of the lip and flange was very rapid until the angle of wear (12deg. to 16deg.) was reached. Unfortunately, there was then very little lip left, and renewals were consequently unnecessarily rapid. With the standard type of curve rails much better results will be obtained. Perhaps, in the near future, curve rails will be rolled of a more suitable material—say nickel steel.

Construction.—It has already been said that the concrete type of construction will in all probability remain standard in this country. There is nothing to show but that, all things considered, it is the most suitable. Public opinion in this country demands a better appearance of the street surface than elsewhere, and this means that the tracks must be laid and maintained in such a manner as to give the least obstruction to vehicular traffic. The best way to accomplish this is to lay both paving setts and rails on an unyielding foundation. Notwithstanding that the best cement is that which is slow setting, progressing slowly and uniformly to its maximum strength, tramway conditions are such that quick-setting cement is essential. If the work could be protected from traffic for a long period, slow-setting cement might be used with advantage, but this is generally an impossible condition. The proportions to make a good concrete are often specified in a misleading way. For instance, 6 to 1 concrete is mentioned in a schedule, and described in the specifications as 4 parts broken stone, 2 parts of sand and 1 cement. Such a mixture is in reality nearer a 4 to 1 than a 6 to 1. Ballast, or pit gravel, if suitable, is often allowed to be substituted for the mixture of sand and broken stone. In this case a mixture of 6 of gravel to 1 of cement is considered for all practical purposes the equivalent of the mixture of 4 of stone to 2 of sand. A little consideration will show that this cannot be the case. A suggested variation in the specification is that the sand and stone shall be mixed in specified proportions, and that the concrete shall consist of a mixture of so much of the aggregate to 1 of the cement. If, for example, 6 to 1 concrete is intended, this could be specified 6 of the aggregate to 1 of cement, the aggregate to be composed of 4 parts of stone to 2 of sand. There are two ways of setting the rails on the concrete, each of which has its partisans. In one case the concrete is laid to within, say, an inch of the proper surface for the base of the rail, and the rails are then laid on the concrete and surfaced by blocks or wedges. The space between the base of the rail and the top of the concrete is packed in with fine concrete. The principal disadvantage of this method is that the surfacing of the rails to the required levels may diminish the packing space to such an extent that only a very thin skin of fine concrete can be placed between the base of the rail and the foundation, properly speaking. The vibratory action of the rails due to the car traffic may crack, pulverise, or otherwise injure this thin layer of concrete or mortar. The other way is to block up the rails to the required levels first, and then place the concrete in one operation. To do this the concrete needs to be made rather wet, so that it will have the characteristics of a quaking mass. The concrete should also be carried up beyond the base of the rails on each side, and worked well under the rails, and then all smoothed off with the shovel before it is set. If the work is properly done, this method should give the better result. Great care should be exercised that the foundation on which the concrete rests

* Paper read before the Tramways and Light Railways Association.

Digitized by Google

is sufficient to properly carry the cars and regular street vehicular traffic. If the foundation is insufficient there will be settlements of the concrete, and consequent damage to the work. It is a trying problem to the engineer to know just what to do in case the subsoil looks at all treacherous. Additional depths of concrete will answer in some cases where the settlements are not uniform, but in small pockets. The concrete in this case will act as a bridge or an arch to carry the load over the weak spots. In case uniform settlement is to be expected a sleeper construction would be the safest. This would be on the principle that there will be a settlement, and that the cheapest means of resurfacing the track one or more times until all the settlements have taken place will be to lift the rails and sleepers and repack under the latter. In this case, of course, concrete between the sleepers for paving foundations would be inadvisable. Broken stone ballast would be the best for temporary purposes until all settlement had taken place, and then finally the whole could be permanently concreted. If a concrete foundation is required at first, it might be practical to use ferro-concrete under and beyond the track for the purpose of increasing the bearing surface of the track without using a prohibitive depth of concrete. Fortunately, such cases are comparatively rare, and when they are met there must be some extraordinary means taken to prevent settlement and consequent damage to the work, or, on the other hand, to recognise that this will occur, and design the road bed so that the repairs can be made later at a minimum cost.

A very interesting variation from the usual type of construction is that adopted by Mr. A. E. White, M.I.C.E, at Hull. This is undoubtedly familiar to all, so no extended description of it need be made. The construction is essentially a concrete one, but there is interposed between the rail and the concrete a creosoted Baltic redwood sleeper 4in. deep and 7in. wide. A similar construction was used in the Third-avenue conduit construction in New York, a continuous wooden stringer being placed between the rails and the yoke seats. The purpose of this wood liner is to provide some elasticity to the running rail, and, consequently, a more noiseless and perhaps easier riding track. Such a track must in no way be confounded with what is known generally as the sleeper construction, so widely used in America. The longitudinal sleeper in Hull is merely a cushion between the rail and the concrete foundation. The rail used in Hull has novel features. The groove is in the centre, with two narrow treads on each side. The wheel, of course, has two treads and a central flange. The advantage of such a rail is that there is uniform wear each side of the groove. The joints are bevelled to an angle of 45deg. This type of rail can in the very nature of things have little general use, for the reason pointed out by Mr. White—viz., that it cannot be connected up for intercommunication with systems on which the ordinary rail is used. If what has previously been stated on the subject of rail joints is true, the good results shown in Hull with these joints should be due to other causes. Mr. White writes "that comparatively little trouble has been experienced with the rail joints, and the rhythmic hammering of the car wheel as it passes over the joint is not heard on the Hull system in the same way as in most other systems which have been in operation for any length of time with ordinary joints. The two routes first constructed have now been running for over five years, and, until during the last few months, the rail joints have had practically no attention. We are now, however, having them all tried over with a straight edge, and all joints which are in any way loose, or show a depression of more than $\frac{1}{16}$in. on a 5ft. stretch with the straight edge, are being opened out, packed where required, and tightened up." Mr. White further points out that, making due allowance for extraordinary expenses connected with the maintenance of the permanent way, there is left a sum of £700 for ordinary maintenance. This for a car mileage of 2,500,000 makes an expense of ·067d. per car mile, which is only about one-quarter of that usually found on tramlines that have been running for this period, which is certainly very satisfactory. Personally, I believe that this result is in a great measure due to the care which must have been exercised originally in the construction of the lines, and that the special features of the construction, if contributory to the good result, are only so in a minor degree.

There is a very marked tendency in permanent-way construction now to anchor firmly the rails to the concrete bed. The object of this is to prevent the working of the rails under the rolling action of the cars. The principal disadvantage in the vertical motion of the rails is to produce a joint between the abutting paving and the rails. Whether anchoring will prevent this, and, if so, what form of anchors should be used, and the reqnisite spacing, will have to be determined by experience. There is one thing that is quite evident—viz, that the amount of movement is slight, and that any anchor which allows the slightest play between it and the rail, or between it and the concrete, will not be efficient.

Paving.—The author remarks that this must be governed largely by local conditions. From the point of view of maintenance, there can be no question but that granite sett paving is the proper one for tramway tracks, but considerations of another nature have often more force than the permanent-way upkeep of tramlines. Consequently, wood paving has been largely used, especially in streets where the paving from the kerb to the rails is wood. This is quite natural, and the tramway engineer must, in many instances, accept the inevitable, and pave his lines with wood. Outside the question of wear and early renewal of such paving, there is always the danger that the blocks will expand to such an extent that the gauge of the track is endangered. With a 7in. rail and 4in. depth of block there is little, if any, danger of this occurring; the concrete and floating coming up 3in. from the base of the rail surrounds it, so that it is held tightly against any lateral movement. The effect of expansion in this case is that the wood arches from rail to rail. It is quite common to hear a dull, hollow sound when a vehicle passes over such a pavement. With deeper blocks, or shallower rails, or the combination of both, there is danger of the rails moving or tilting. In this case dependence can be placed on the anchors, if such form part of the construction, to prevent the movement of the rails. The tie-rods should be especially strong, placed as high as possible and spaced closely together. My own experience has been that with soft wood thoroughly creosoted there is little or no danger of disturbance to the track from expansion of the wood blocks. With hard wood blocks, which naturally are untreated, this danger exists, and very great precautions must consequently be taken. Tarred macadam has been used to some extent for lines in sparsely settled districts where the roads are but little used. Such pavement must be put down when the weather conditions are suitable. There is but little use in specifying tarred macadam for winter work and expecting good results from it.

In conclusion, the author remarks that there are many other special features of permanent-way construction, but these are too extensive for discussion in a single paper.

DESCRIPTION OF ELECTRIC LIGHT AND POWER SCHEMES IN NEW YORK, WITH SPECIAL REFERENCE TO THE WATERSIDE STATION OF THE NEW YORK EDISON COMPANY.*

BY P. S. SHEARDOWN, MEMBER

(Concluded from page 868.)

POWER STATIONS ERECTED OR IN COURSE OF CONSTRUCTION IN NEW YORK OUTSIDE MANHATTAN ISLAND.

The Edison Illuminating Company of Brooklyn.—The population of Brooklyn as given by the Board of Health estimates for 1903 is 1,313,000 as against 1,929,000 for Manhattan, but Brooklyn covers an area of 77·62 square miles as against 21·95 square miles in Manhattan. To this constituency the Edison Illuminating Company of Brooklyn supplies electrical energy for lighting and power. The first annual report, dated Jan. 1, 1890, shows that there was an equivalent of 6,600 16-c.p. lamps connected to the mains. To-day there is an equivalent of upwards of 800,000 lamps, and the load has grown so rapidly that the 30,000 h.p. in high-class engines at the company's two

* Paper read before the Dublin Section of the Institution of Electrical Engineers.

Digitized by Google

stations will be insufficient to carry it, and two more machines have been ordered and are now in course of construction—one a 5,000-h.p. cross-compound Westinghouse and the other a 10,000-h.p. turbine (the first Parsons turbine to be made in this country by the Allis-Chalmers Company). The company operates two systems, most of the lighting being done from a three-wire direct-current system at 230 volts across the outers, current being supplied to it from rotary converter sub-stations which are supplied with a three-phase 6,600-volt current from the main generating stations. The company also operates a two-phase alternating, 60-cycle overhead system for suburban or sparsely-settled sections. The alternating-current circuits are changed over to direct as rapidly as is warranted by business returns. The exceptional feature of the Brooklyn Company's business is the extent and proportions of its summer load, the peak of which last year was higher on July 4 than on the heaviest day in the previous December. The reason for this is that the Brooklyn Edison Company is fortunate in that it includes within its sphere of operation a district known as Coney Island, which is the greatest summer resort in America, and during the summer is the playground and theatre of amusement to a population within the metropolitan district exceeding four millions. The Coney Island load of the Edison Company begins about May 15 and lasts through until Oct. 1. Most of the lamps in use in Coney Island are of 8 c.p., and this summer their number was upwards of 300,000. One place of amusement in Coney Island, known as Dreamland, alone requires from the Edison Company 45,000 amperes. A decorative tower in the centre of this fête ground alone contains 42,000 lamps.

Power Stations of the Brooklyn Rapid Transit Company.—The Brooklyn Rapid Transit Company operates both the elevated and surface cars in the borough of Brooklyn. If space permitted, many facts of interest could be given of these extremely complex transportation systems. Suffice it to say that Brooklyn acts in part as a dormitory for Manhattan, and includes within its limits the chief summer resorts of New York City, of which the most important is Coney Island. The company own and operate 529 miles of track, of which 461 are surface and 68 elevated. Over these tracks are operated 1,600 surface and 652 elevated cars. Every day 330,000 people are carried across Brooklyn Bridge alone, 290 cars per hour crossing the bridge on the surface lines alone during the rush hours, and 264 elevated cars every hour. As many as 375,000 people have visited Coney Island on one day, there being seven surface and five elevated lines running to West Brighton or Coney Island proper. Power for operating the cars is generated partly as direct current and partly as three-phase alternating at 6,600 volts. The largest power station is of 32,000 h.p. capacity, and the smallest just a little station operating a cable power-house with 225 h.p. capacity. The Kent-avenue station is a direct-current station of 16,000 h.p. capacity. The Southern power station contains six units, each of 1,000 h.p. The Atlantic-avenue power station is a belt-driven station, containing two 800-kw. Walker generators and seven 400-kw. generators. The Thirty-ninth-street station has engines aggregating over 5,000 h.p., and there are two 400-kw. generators located in the Brooklyn Bridge station. To provide for the future growth of the system, a new station known as the Williamsburgh power station has been commenced. The plans provide for an ultimate installation of 66,000 kw. in turbo-generators, or a capacity one-third greater than the combined plants now in use.

Electrification Scheme of the New York and Hudson River Railroad Company.—This railroad company has under construction an electrification scheme of great extent. It embraces the operation of all its ordinary heavy traffic by electric locomotives through a large area north of New York proper, which it approaches through a four-track tunnel, which is now operated by steam locomotives, the gases of the tunnels causing serious inconvenience to the passengers. But this is only one portion of a work of huge magnitude, as they propose putting the whole of their termini yard and station below the street level. The scheme will involve the electrification of nearly 300 miles of single track carrying the most important passenger and mail traffic in the country, and will necessitate the hauling of trains nearly a quarter of a mile in length and weighing as high as 871 tons at speeds exceeding 60 miles per hour, the number of trains handled daily in the Great Central yard being from 500 to 700.

Two central power stations are to be erected and designed for an ultimate capacity of 30,000 kw. After an exhaustive examination of the relative merits of reciprocating engine-driven alternators and turbo-generators, the commission has recommended the use of the latter, and a contract has been entered into for eight 7,500-h.p. turbo-generators, with an ultimate installation of 12. The turbines are of the Curtis type. The system of electrical distribution will be 11,000 volts three-phase alternating, transformed in rotary converter sub-stations to direct current at 600 volts. The locomotive decided on has many interesting features, having a new type of gearless direct-current bipolar motor.

Electrification of the New York Terminus of the Pennsylvania and Long Island Railroads.—The barrier presented by the great rivers surrounding Manhattan Island (as well as the topography of the city and the high value of its real estate) have been a stupendous obstacle to the running into Manhattan Island itself of many of the large railway companies, and much as this end was desired by both the companies themselves and the general public, many of the large railway companies have till now had their termini stations on the Brooklyn or New Jersey sides of New York; the traffic from New York City to these termini being carried by means of ferries. Prior to the successful development of electric traction for heavy railway service, the bridging of the river appeared to be the only satisfactory solution of the problem, but the physical and financial barriers have been so great that this scheme has never been carried out, but now that the electric locomotive has proved itself so successful in hauling heavy trains, both the Pennsylvania and the Long Island Railway Companies have started subways under the rivers into New York. The entire traffic is to be worked through these subways to the termini stations in New York by electric locomotives. To operate these two systems, two power stations are to be erected. The New Jersey power station will have an ultimate capacity of eight 5,500-kw. units, the Long Island power station an ultimate capacity of 12 5,500-kw. units. In addition to the above, both power stations will be equipped with separate lighting units to take care of the important requirement of reliable lighting of the tunnel lines and termini buildings. For the initial equipment to operate the Atlantic division of the Long Island Railroad, the Long Island power house has been commenced, and is expected to be in operation by the spring of 1905.

PHYSICAL SOCIETY.

At the meeting of the above society, held on the 9th inst. at the Central Technical College, a paper on "**A High-Frequency Alternator**" was read by **Mr. W. Duddell.** The author described and showed in action a high-frequency alternator which he had constructed in 1900 for some experiments on the resistance of the electric arc, and with which frequencies up to 120,000 ⌒ per second had been obtained. The alternator consists of an inductor, built up out of ferrotype plate, having V-shaped notches cut in its edge so as to have flat-topped teeth. Surrounding the inductor is a laminated ring having two inwardly projecting poles, the clearance between these and the teeth of the inductor, which formed the air-gap, being less than 0·1mm. The ring is wound so that a direct current flowing round the winding tends to produce lines of force from one pole to the other through the inductor. The number of lines of force varies from a maximum when the teeth of the inductor are opposite the poles to a minimum when the poles are in front of the spaces. This variation in the total number of lines of force produces alternating E.M.F.'s in any winding either on the pole-pieces or on the ring itself; the movement of the inductor through the distance between two consecutive teeth producing one complete period. One winding on the ring could serve to carry both the direct field current which magnetises the ring and the alternating current produced. In practice, owing to the great importance of any self-induction in the alternate-current circuit, it was found advisable at high frequencies to use separate windings for the two currents. At the highest frequencies the best results were obtained with coils having a few turns of wire fixed right on the tips of the poles. The alternator is driven by means of a figure-of-8 belt drive from two phosphor-bronze discs. Each of these discs is belted to a double-grooved pulley fixed on the shaft of a direct-current driving motor. With this method of drive the inductor was run for several months at speeds between 30,000 and 40,000 revolutions per minute, and the spindle of the inductor alone could be easily run at 60,000 revolutions per minute. Using inductors having 30, 60, 90, and 204 teeth, the author obtains small alternating currents having frequencies from a few hundred periods per second up to 120,000 ⌒ per second. An illustration will perhaps convey some idea of how high a frequency of 120,000 ⌒ per second really is. In plotting curves for ordinary frequencies of 50 to 100 ⌒ per second, a scale often adopted is 10in. for 100 ⌒. If it were attempted to plot a curve up to 120,000 ⌒ per second to this scale, the curve paper would require to be 120,000in., or nearly *one fifth of a mile long*. Many difficulties were encountered with the centrifugal forces on the driving belt, and the author finally obtained the best results with a spliced cotton cord. Working drawings of the alternator characteristic curves and its wave-form are given in the paper. During the construction of the alternator bicycle wheels were used to drive it, and curves are given showing the very large power taken to drive these wheels, owing to air friction. A table is given of all the high-frequency alternators which have come to the author's knowledge, and he would be glad to receive any missing data or data of other machines to include in the table before it is finally printed.

Dr. J. A. Fleming said he had felt surprised on hearing about Mr. Duddell's alternator that he had been able to reach any such frequency as 120,000 ⌒ per second. It spoke highly of the excellent mechanical means employed. On the other hand, as far as its use in wireless telegraphy was concerned, it was no use to speak of a machine even if it gave this frequency, corresponding to a wave 1½ miles in length, if the output of the machine were only a few watts. If it were 150 h.p., it might be different. The difficulty with most high-

Digitized by Google

frequency alternators was the magnetic leakage. Dr. Fleming then described some of the devices adopted by Tesla for obviating this defect. Many of the high-frequency alternators made had their power overestimated. Hitherto the frequency reached had been only about 10,000 ⁓ per second. A machine of this last frequency would be no particular assistance in wireless telegraphy. Such machines were, however, very useful for research and demonstration purposes.

Prof. W. E. Ayrton gave an **"Exhibition of Experiments to show the Retardation of the Signalling Current on 3,500 Miles of the Pacific Cable between Vancouver and Fanning Island."** The experiments were performed upon a cable electrically equivalent to the portion of the Pacific Cable between Vancouver and Fanning Island, the product of the capacity (in microfarads) and the resistance (in ohms) being nine millions. Three dead-beat galvanometers were employed to indicate the current at the beginning, in the middle, and at the end of the cable. It was shown that upon applying an E.M.F. at one end of the cable the current at that end was enormously greater than its steady value, and that one-fifth of a second elapsed before any indications of current were shown at the far end of the cable. By that time the current at the sending end was 3·7 times its steady value, and after two-fifths of a second it had fallen to 2·3 times its steady value. In about five seconds the current became steady.

The electrical laboratories of the college were open to the inspection of Fellows, a special feature being an exhibition of Ayrton-Mather galvanometers (showing the evolution of the present commercial instruments from the earliest types, constructed in the college), universal shunts, and electrostatic instruments.

LEGAL INTELLIGENCE.

UNDERGROUND ELECTRIC RAILWAYS OF LONDON v. THE COMMISSIONERS OF INLAND REVENUE.

The case of the Underground Electric Railways Company of London, Limited, *v.* the Commissioners of Inland Revenue came before the Court of Appeal, composed of the Master of the Rolls and Lords Justices Stirling and Mathew, on the appeal of the Commissioners from a judgment of Mr. Justice Channell in the King's Bench Division.

This was a special case, raising a question as to the amount of stamp duty payable by the company under the agreement by which it acquired control of the Brompton and Piccadilly-circus Railway, the Charing Cross, Euston, and Hampstead Railway, the Great Northern and Strand Railway, and the Baker-street and Waterloo Railway.

From the special case it appeared that by an agreement dated June 25, 1902, with the Metropolitan District Electric Traction Company, Limited, the Underground Electric Railways Company, which had a capital of £5,000,000, agreed to purchase the whole of its undertakings. On July 8, 1902, an instrument was presented on behalf of the new company for the purpose of being stamped, and the Commissioners, in assessing the duty payable, computed the consideration for the property agreed to be sold at £1,947,683. 18s. 5d., which, after making certain deductions, was put at £1,527,357. 17s. 11d. The question was whether the Commissioners were right in including therein £780,000 under Clause 3 of the agreement, which provided for the payment to the Traction Company of a certain share of the profits as part payment of the purchase money, after provision had been made for the general body of shareholders. The Commissioners held that the sum contingently payable out of the profits was "part of the consideration for the sale," and that so far as such sum was capable of ascertainment at the date of the agreement, it was liable to *ad valorem* conveyance duty. The company, on the other hand, submitted such sum as incapable of assignment, by reason of the remoteness of the contingency upon which the payment must be made. Mr. Justice Channell gave judgment for the Underground Electric Railways Company, with costs. Hence the present appeal of the Commissioners.

At the conclusion of the arguments of counsel, their **Lordships** upheld the contention of the Commissioners, reversed the decision of Mr. Justice Channell, and entered judgment for the Crown. The appeal was according allowed, with costs.

Mr. Roskill applied for a stay of execution, with a view to his clients considering whether they would appeal to the House of Lords.

Their **Lordships** granted a stay for a month.

DEWSBURY PAINTER'S ELECTRIC SHOCK.

An action came before Mr. Justice Darling last week at the Leeds Assizes, in which Parker Harrop, journeyman painter, claimed damages from Mr. N. Ramsden, painter, Dewsbury, for personal injuries alleged to have been due to negligence on the part of the defendant.

Plaintiff, while in defendant's employ, was painting the posts of the tramway company. The defendant's instructions were that when the men were painting standards in the centre of the road they must get down from the ladders if a tram was passing, but it did not matter when painting the ordinary standards. When the accident happened, plaintiff was not supplied with gloves. He was on a ladder about 20ft. from the ground, and a boy was holding the ladder at the foot. He was holding on to the ladder with his right hand and was reaching over with his left hand, bolding the brush in his left hand, when he received a violent electric shock. How, he did not know; but the experts seemed to think it probable that he touched the trolley wires. The result of the shock was that he was drawn off the ladder and up to the arm. He managed to tear himself loose, and fell to the ground. He was taken to Dewsbury Infirmary, and remained there 14 weeks. Both arms were badly fractured, his back was hurt, and his hands were burnt. He had been deaf ever since, and was now unable to follow his trade as a painter. He had not worked since the accident. Plaintiff contended that there ought to have been indiarubber gloves and a derrick.

The **Defendant** stated that he was unaware of any danger so long as the live wire was not touched, and he warned his men every morning to be careful not to touch the wires. No one suggested to him before the accident that he should provide rubber gloves. Immediately he was told of them he provided his men with them.

His Lordship, in summing up, mentioned that in the hearing it had come out that the defendant was insured, but he warned the jury to guard against giving heavy damages on that account, if they should decide to give damages at all. He put the following four questions to the jury.

Did the injury occur by reason of want of proper care on the part of plaintiff himself?—Yes.

Did the defendant neglect to supply the plaintiff with appliances proper to be used in doing the work in which he was employed?—Yes.

Did the defendant know it was dangerous even for a careful workman to do the work without gloves?—No.

Was it negligent of the defendant not to have made himself aware that it was dangerous to do the work without wearing gloves?—Yes.

The jury added "£75 damages."

Subsequently, his **Lordship** alluded to a point of law to which the jury's answers had given rise. These answers amounted to a verdict for the defendant, but as the amount of damages named was very moderate he hoped the matter would be settled.

WEST HARTLEPOOL TRAMWAYS.

At West Hartlepool Police Court the General Electric Company, Limited, were summoned under the tramways order by the West Hartlepool Corporation for not keeping the tramway in Clarence-road in a proper state of repair.

For the Corporation it was stated that the company had entirely failed to recognise their obligation to keep the track in a proper state of repair. The condition of the track was such that in some places the rails were below the setts.

For the defence it was stated that negotiations were proceeding with regard to the tenure of the tramways, and that as soon as terms had been arrived at, the company intended to reconstruct the line.

The Bench found the case proved, and imposed a fine of £5 for the first offence and £1 a day for seven subsequent days.

Another summons charged the company with failure to keep the wooden setts in Grange-road in good condition, the result being that in wet weather the road became slippery.

This charge was dismissed.

A third charge referred to the use of three cars which were not free from noise produced by the clatter of machinery.

A fine of £5 and costs was imposed, and another charge was withdrawn on payment of costs.

TRAMWAY ACCIDENT.

Godfrey Pearson sued the Bradford Corporation for damages for personal injuries received in a tramcar accident between Bradford and Wyke.

The plaintiff was travelling to Wyke on a tramcar belonging to the Bradford Corporation. After passing Odsal Top the road takes a long, steady descent to Low Moor. The car reached a considerable speed, and came into collision with a wagon coming in the opposite direction and loaded with looms. The side of the car was partially torn off, the glass was broken, and the plaintiff, who was seated with his back to the damaged side, received severe injuries. He was confined to his bed for a month, and so great was the shock to his system that he was kept from business three months. The Corporation's defence was that the driver of the wagon swerved into the car and caused the accident, and that the driver of the tramcar was not to blame.

The jury awarded £350 damages.

COMPANIES' MEETINGS AND REPORTS

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS.

The directors' report for the year ending Sept. 30, to be presented at the forty-first ordinary general meeting of the shareholders on the 20th inst., states that, after provision for doubtful debts, there is a net profit of £11,343. 19s. 3d. Adding £66,930. 7s. 10d. brought forward, and deducting £12,500 interim dividend paid in June, there remains a disposable balance of £65,774. 7s. 1d. The directors recommend the distribution of a dividend of 5s. a share, free of income tax, amounting to £12,500, making, with the interim dividend paid in June, a total payment of 5 per cent. for the year, and leaving £53,274. 7s. 1d. to be carried forward. The general business of the Company shows an increase when compared with last year, but, unfortunately, the sales have been made on a rapidly rising market for raw material, and the selling prices of manufactured goods have not proportionately increased. Moreover, the revenue for the year has been charged with amounts expended on the development of a new business which has not yet reached a remunerative stage. These two causes account for the serious falling off in revenue, but the directors think that the revenue for the current year will not be injuriously affected to a like extent. The "Dacia" and "Buccaneer" have been employed in cable-repairing work during the year, and these two vessels are at present under charter. The works at Silvertown and Persan have been maintained in their usual state of efficiency, and extensions continue to be made. In April last the Board made an issue of £100,000 second debentures.

Digitized by Google

POWER-GAS CORPORATION.

The following is an abstract from the managing director's report, which was presented and approved at a meeting last week: "Electricity can be produced cheaper by Mond gas-driven generators than in any other way; but engineers of central electric stations in this country have not yet made up their minds as to the feasibility of running large gas-engines in parallel for the production of alternating current, although many such installations can be seen running in parallel abroad, particularly in Germany. We hope that the North-Western Electricity and Power-Gas Company will now soon place itself on a working basis, and proceed with the erection of its first central electric station, which is to be driven by power-gas and large gas-engines, and will thereby furnish us with an object lesson, the importance of which to the development of our business cannot be over-estimated."

LANCASHIRE POWER CONSTRUCTION.

The report for the period ended Sept. 30 last, to be presented at the meeting on the 16th inst., states that there remains £90,000 still to be called up on A shares and £116,000 of B to be issued. The directors anticipate that the further calls on the A shares will require to be made and the B shares to be issued (to the contractors under their respective agreements) during the next few months. Satisfactory progress has been made with the construction of the power station at Radcliffe and the directors expect to have these works ready for supplying power early in the coming year. Negotiations are proceeding with a number of the local authorities for giving a supply in their respective districts, and an agreement has already been entered into with Swinton and Pendlebury.

SOUTH WALES ELECTRICAL POWER DISTRIBUTION.

An extraordinary meeting of the South Wales Electrical Power Distribution Company was held last week, when a resolution was passed authorising the directors to create £50,000 additional debenture stock, bearing interest at the rate of 5 per cent. per annum (being the third instalment of £50,000, part of the £250,000 which the Company is empowered to borrow under Section 26 of the said Act), and to issue the same as the directors think fit.

NEW COMPANIES REGISTERED.

Donne and Willans, Limited. — Capital, £5,000. Object: to acquire and carry on the business of manufacturers, etc., of motorcars and cycles carried on by M. Donne at 27, St. John's-square, Clerkenwell, E.C., and that of engineers, machinists, electricians, metal workers, etc.

Supplies, Limited —Capital, £5,000. Object: to carry on the business of electricians, mechanical engineers, producers and suppliers of electricity, motive power, and light, etc. Registered office: 12, St. John's-lane, Liverpool.

W. W. Bamford, Limited.—Capital, £2,000. Object: to carry on the business of electrical, mechanical, consulting, and practical engineers, manufacturers of and dealers in electric, magnetic, telegraphic, telephonic, and other apparatus, etc. Registered office: Deepwater Pier, Northfleet, Kent.

Brynamman and District Electric Supply Company, Limited.—Capital, £2,000. Object: to carry on the business of suppliers of electricity in all its branches, electrical and mechanical engineers, etc. Registered office: Brynamman, Carmarthenshire.

Cheshire Light Railways, Limited.—Capital, £1,500. Objects: to obtain from the Light Railway Commissioners, or other authority, any orders authorising the construction of light railways in Cheshire, or elsewhere in the United Kingdom or abroad, and to carry on the business of light railway proprietors, manufacturers of and dealers in railway and tramway carriages, motorcars, etc.

Lindsey Light Railway Syndicate.—Capital, £1,000. Objects: to apply for and obtain orders for a light railway, under the provisions of the Light Railways Act or other statute, beeween Blyton and Frodingham, Lincs., and to carry on the same.

Aberavon District Tramways Syndicate, Limited.—Capital, £2,000. Objects: to apply for a provisional order or Act of Parliament authorising the construction of an electrically-equipped tramway in the parishes of Aberavon and Margam, Glamorganshire, and elsewhere; to construct or acquire tramways, etc. Registered office: Arlington-chambers, 4-5, Commercial-street, Newport, Mon.

Mors, Limited.—Capital, £15,000. Object: to acquire English patents relating to motorcars of the Société Anonyme d'Electricité et d'Automobiles Mors, or others, to manufacture and sell in the United Kingdom and British Colonies and dependencies motorboats and accessories, etc., including those made by the Compagnie Française des Voitures Electromobiles. Registered office: 55-59, Shaftesbury-avenue, W.C.

Marlborough Electric Supply Company, Limited.—Capital, £1,000. Objects: to carry on the business of suppliers of electric light and power, electrical engineers, electricians, contractors, tramway and railway proprietors, etc., and to enter into an agreement with the Bristol Trust, Limited, whereby the said trust undertakes, in consideration of £250, to pay the costs of formation and registration and certain preliminary expenses.

Climax Motors, Limited.—Capital, £5,000. Object: to manufacture and deal in motors, carriages, and vehicles, whether for propulsion by steam, electricity, oil, or other power

Liens Registered.

Chiswick Electricity Supply Corporation, Limited, London, E.C.—Lien registered Dec. 1, for £500 4½ per cent. debentures, part of £50,000; amount previously issued, £33,000. No trustees. Charged on the undertaking and all the property, present and future, including the uncalled capital for the time being.

Perth Electric Tramways, Limited, London, E.C. — Lien registered Nov. 25, for £500 6 per cent. debentures, part of £50,000; amount previously issued, £35,500. No trustees. Charged on the benefit of certain agreements, deposit, provisional order, and Acts of Parliament, tramways and tramway undertaking, plant, machinery, etc., in Perth, Western Australia.

Milford-on-Sea Electric Supply Company, Limited.—Issue on Nov. 12 of £850 debentures, part of a series created Sept. 3, 1904, to secure £2 000, charged on the company's whole property, present and future. No trustees. No previous issue of same series.

APPOINTMENTS VACANT.

Car-Shed Superintendent, Blackburn Corporation tramways. Wages, £2. 10s. per week. Applications by Dec. 22. See advertisement.

Works Manager, small accumulator works. Salary to commence, £150 per year. See advertisement.

Electrician, National Telephone Company, Limited, Royal Exchange, Glasgow. Salary to start, £100 per annum. See advertisement.

Publicity Department Manager, electricity works, Croydon. Salary, £150 per annum. Applications by Dec. 27 to Borough Electrical Engineer.

Electrical Engineer, Elland Urban District Council. Applications by Dec. 17 to Mr. James Clarkson, Council Offices, Southgate, Elland.

Electrical Engineer, Worcester Corporation. Salary £400, rising by instalments of £20 per annum to a maximum of £500. Applications to the Town Clerk by 10 a.m. on Dec. 19.

Various, Bridlington Town Council. Assistant Engineer, £100 per annum; Clerk, £75 per annum; Engine-Driver, 35s. per week; Jointer, 30s. per week; Arc Lamp Lighter, 30s. per week; Stoker, 13s. per week; Cleaner, 21s. per week; Jointer's Mate, 12s. per week; Trimmer's Mate, 12s. per week.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Guirgia (Roumania).—Tenders are required for the electric lighting of the town. Particulars from the town's secretary. Tenders by Jan. 28, 1905.

Erith.—The Urban District Council invite tenders for motorcars, trucks, motors, and equipments, track sweeping and watering car. Tenders by Dec. 19.

Neath.—The Corporation invite tenders for the supply and delivery of electric wattmeters. Specification on application to the Town Clerk. Tenders by Dec. 28.

Paris.—Tenders are required for electric cable, bronze and copper wire. Particulars from Post and Telegraph Department, 103, Rue de Grenelle. Tenders by Dec. 21.

Swindon.—The Corporation invite tenders for the supply and erection of one 300-kw. steam dynamo, or, alternatively, one 400-kw. steam dynamo. Tenders by Dec. 20.

Bradford.—The Corporation invite tenders for the supply of miscellaneous stores required by the tramways department during the year ending Dec. 31, 1905. Tenders by Dec. 17.

Almendrajo (Spain).—Tenders are invited for public electric lighting for 10 years. Particulars may be obtained from the Secretary of the Ayuntamiento of that town. Tenders by Dec. 22.

Caen (France).—The Prefect requires tenders for concession of a tramway from Ryes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1, 1905.

Rochdale.—The Corporation invite tenders for high-tension three-phase switchgear and extensions to the low-tension continuous-current switchboards. Tenders to Mr. Wm. Henry Hickson, town clerk, by 27th inst.

Sunderland.—The Corporation invite tenders for the supply of one wooden cooling tower capable of cooling the circulating water for a surface condenser dealing with 30,000lb. of steam per hour. Tenders by Dec. 30. See advertisement.

Madrid.—The call for tenders for the service of the electric lighting of Almendralejo was without result. The conditions of contract have, therefore, been modified in certain respects, and tenders are to be called for to be opened on Dec. 22.

Fulham.—The Council require tenders for the supply and erection of a 3,000-volt steam alternator of 1,000 kw. capacity, coupled to a Belliss engine, at their generating station, Townmead-road. Tenders to Town Clerk not later than 12 noon on Dec. 20.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Digitized by Google

Port Elizabeth.—Messrs. Davis and Soper, 54, St. Mary-axe, E.C., agents of the Municipal Corporation of Port Elizabeth, South Africa, invite tenders for various works in connection with the Corporation electricity supply undertaking. Tenders by Jan. 16, 1905.

Erith.—The Urban District Council invite tenders for overhead line equipment, poles, etc.; underground feeder cables, boxes, etc.; rotary converters, transformers, and motor-booster; and main high and low tension switchboards, cable connections, etc. Tenders by Jan. 9. See advertisement.

Johannesburg.—The Municipal Council invite tenders for two 35-ton electric overhead travelling cranes and transformer pillars and switchgear. Tenders must be addressed to Messrs. Mordey and Dawbarn, 83, Victoria-street, Westminster, S.W., and received by them not later than Dec. 27.

Southend-on-Sea.—The Corporation invite tenders for additional plant for their generating station, comprising the following: two boilers, one steam dynamo, one fuel economiser, two electrical feed pumps. Tenders to be delivered at the offices of Mr. William H. Snow, town clerk, Southend-on-Sea, by Dec. 21.

Glasgow.—The Corporation invite tenders for the supply of 100 electric motor equipments and spare parts for same. Specification, etc., can be obtained on application to Mr. James Dalrymple, general manager, 102, Renfield-street, Glasgow. Tenders must be lodged with Mr. James G. Monro, town clerk, City Chambers, Glasgow, by 10 a.m. on Dec. 22.

Spain.—The *Gaceta de Madrid* of Dec. 6 notifies an application by the Compañia General de Tranvias for the concession of an electric tramway from Sans to Coll-Blanch. One month from the date of the publication of this notice is allowed in which other proposals on more favourable terms, duly guaranteed, may be made. The *Gaceta* may be seen at the Commercial Intelligence Branch of the Board of Trade.

Valladolid.—Tenders are required for the public lighting by means of electricity of the city of Valladolid. Fifteen hundred incandescent lamps of 17 c.p. will be required. The concession will terminate on Dec. 31, 1911. The annual payment to the concessionnaire will be about £965. A deposit of £48 is required to qualify any tender. The adjudication will take place at 11 a.m. on Dec. 26, at the Casa Consistorial, Valladolid.

Perth (Australia).—Tenders are invited by the Duputy-Postmaster-General for the supply of the following telephone material; 19½ miles 26-pair lead-covered cable, dry core, to standard specification No. 7; 5,000 paper sleeves, 3in. long by $\frac{7}{16}$in. diameter; 350 yards paper strips, 2in. wide. Conditions, etc., may be obtained at the General Post Offices at Perth, Adelaide, Melbourne, Sydney, Brisbane, and Hobart. Tenders by Dec. 28.

Ilford.—The Urban District Council invite tenders for the installation of a telephone fire-alarm system on the double or metallic principle. Particulars and form of tender may be had on application to Mr. H. Shaw, A.M.I.C.E., surveyor, Town Hall, Ilford, on payment of a deposit of £2. 2s., which will be returned on receipt of a bona fide tender. Tenders, addressed to the Chairman, must be sent to Mr. John W. Benton, clerk, town Hall, Ilford, by Dec. 19.

Shanghai.—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

Bromsgrove (Worcs.).—The Visiting Committee invite tenders for the supply and erection at their new lunatic asylum of the following plant: (Section A) engines, dynamos, booster, and steam services; (B) storage battery and accessories; (C) main switchboard, ring main, feeders, distribution boards, wiring, lamps, and accessories. Specification, etc., may be obtained from Mr. Robert J. Oliver, clerk of the Visiting Committee, Shirehall, Worcester, on payment of £5 for each section of the work as above, which will be returned on receipt of a bona fide tender.

London, W.—The Great Western Railway Company invite tenders for the supply and delivery of the following material required in connection with the electrical equipment of the Hammersmith and City Railway, etc.: (Specification No. 8) steel conductor rails, cast-iron and steel ramps and fastenings; (9) porcelain insulating supports and their fastenings for conductor rails; (10) copper bonds, insulated cable connections, cable terminals, bonding presses, and accessories for connecting up conductor rails. Tenders, addressed to the Secretary, Great Western Railway, Paddington Station, W., will be received on or before Jan. 3.

Cardiff.—The Corporation invite tenders for the following plant for the extensions to their power station on the extra high-tension three-phase system—viz.: two 1,600 slow-speed vertical engines, two 1,100-kw. three-phase alternators, four Lancashire boilers with accessories, steam and other piping, switchboard gallery and staircase extensions to central service gangway, extra high-tension three-phase feeder cables. General conditions, specification, and form of tender may be obtained on application from Mr. Arthur Ellis, M.I.M.E., M.I.E.E., borough electrical engineer and manager, Central Offices, The Hayes, Cardiff. Tenders to be delivered at the office of Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff, by Dec. 19.

Madrid.—Tenders are invited for the public lighting by means of electricity of the town of Villanueva y Geltru for a term of 10 years. Twenty-four arc lamps of 500 c.p. and 239 incandescent lamps of 20 c.p. will be required. The concessionnaire will be allowed to supply private individuals without payment of a municipal tax subject to his supplying, free of charge, the Casa Consistorial with 75 kw. per month. He will be required to maintain a duplicate set of machinery in order to avoid the possibility of the town being left in darkness through a breakdown. The annual payment (upset price) to the concessionnaire will be 23,145 pesetas (about £678). The adjudication will take place on Dec. 24. A deposit of £68 is required to qualify any tender.

Madrid.—The *Gaceta de Madrid* of Nov. 9 publishes a notice inviting tenders for the construction and working for 60 years of an electric tramway between Azcoitia and Zumaya (Province of Guipúzcoa), in accordance with certain conditions set out in the *Gaceta*. An application for this concession has already been received from Don Dionisio Sorseta Garcia, who, at the same rates, will enjoy certain preferential rights over other tenderers. The competition will turn, in the first place, on the reduction of the tariff fixed for the conveyance of passengers, etc.; in the event of equal terms being offered, it will turn on a reduction of the period of concession. Adjudication of tenders will take place before the Director-General of Public Works, Madrid, on Jan. 10. A deposit of 16,297 pesetas (about £475) is required to qualify any tender

Manchester.—Tenders are invited for (Contract C) switchboards, mains, feeders, etc., for supply of electric current for power and lighting, and for arc lamps, etc., in connection with the new dock works, Salford, for the Manchester Ship Canal Company. (Contract D) for mains, feeders, etc., for the supply of electric current for power and lighting, and for arc lamps, etc. Drawings for both contracts can be inspected and copies of specifications, bills of quantities, and forms of tender can be obtained at the office of Mr. W. H. Hunter, M.I.C.E., chief engineer to the Manchester Ship Canal Company, 41, Spring-gardens, Manchester, on payment of a sum of £3. 3s., which will be returned on receipt of a bona fide tender. Tenders to be addressed to Mr. F. A. Eyre, secretary, Manchester Ship Canal Company, 41, Spring-gardens, Manchester, by 10 a.m. on Dec. 22.

RESULTS OF TENDERS.

Belfast.—The North-Eastern Steel Company, Middlesbrough, have obtained an order for 10,000 tons of rails for the Belfast tramways.

Whitby.—The Urban District Council have accepted the tender of Babcock and Wilcox, at £945, for a new boiler, including mechanical stoker.

Walsall.—The Electricity Committee have ordered from J. Russell and Co., Limited, Walsall, the steam connection for No. 6 boiler, at a cost of £83.

Monte Video.—A tender of J. G. White and Co., Limited, 22A, College-hill, E.C., exceeding £400,000, has been accepted for the reconstruction of the tramways.

Tooting Bec Asylum.—The Asylums Board have accepted the tender of F. W. Potter and Co., at £32. 10s., for supplying and fixing dynamo belt guards for electric light plant.

Cardiff Asylum.—The sub-committee have recommended that the tender of Messrs. Bradford, of London, amounting to £3,000 odd, for machinery for the laundry, to be driven by electricity, be accepted.

Deptford.—The Borough Council have accepted the tender of the Hart Accumulator Company, Limited, Marshgate-lane, Stratford, E., for additions and alterations to the existing battery installed at the public baths, New Cross S.E.

Colliery Power Plant.—The British Electric Plant Company, Limited, Alloa, have been awarded by the Alloa Coal Company the contract for a complete electric power plant on the direct current system for the Bannockburn Collieries, together with engines for the same.

Lowestoft.—The Town Council have accepted a tender for supply of 1,500 yards of cable for crossing the harbour of W. E. Dennis and Co., of 49, Queen Victoria-street, London, at £23 per 100 yards, provided a guarantee of electrical maintenance for five years be given, that the firm test after the cable is laid up to 1,000 volts at their own expense. The tender of the Callender Cable and Construction Company to supply feeders at £535 per 1,000 yards has also been accepted. N.B.—The engineer has stated that he would lay the feeders with his own staff at a cost for labour of about £100.

Burslem (Staffs).—The Guardians of Wolstanton and Burslem Union have accepted the following tenders for the supply and erection of the electric lighting plant at the workhouse, Chell—(Section A) water-tube boilers, etc.; (C) two 25-kw. steam dynamos and booster; (D) switchboard; (E) cables and wiring; (F) accumulators; (G) arc lamps: (A) Stirling Boiler Company, Motherwell, at £550; (C) McClure, Whitfield and Co., Stockport, £764. 7s.; (D) Electric and Ordnance Company, Limited, Birmingham, £183. 19s. 8d.; (E) E. M. Evans, Manchester, £644. 5s. 8d.; (F) Pfluger Company, London, £297. 2s. 6d.; (G) Crompton and Co., London, £148.

Yarmouth.—Fourteen tenders have been received for steel rails, fishplates, soleplates, tiebars, and bolts for the Gorleston tramways, but only six were complete quotations. Of these three were for Belgian manufactured material, one did not state the place of origin, and the other two were from Barrow-in-Furness and Leeds. Two partial tenders came from Middlesbrough. The schedule on which all tendered was for 800 tons of straight rails, 25 tons curved rails, 50 tons of fishplates, 13 tons soleplates, 21 tons of tiebars, and 10 tons of bolts and nuts. The totals of the tenders worked out thus: Jacobs Bros. and Co. (Belgian), £4,665. 16s. (accepted); Le Bas (Belgian), £4,749. 8s. 2d.; A. Penny and Co. (Belgian), £4,919. 7s. 6d.; MacClellan and Co. (not stated), £5,141; Barrow Steel Company (English), £5,174. 2s. 6d.; W. Scott (English), £5,651. 10s. The surveyor stated that the total for two other English firms, both of Middlesbrough, could be made up thus: Bolckow, Vaughan, and Co., £5,257. 12s. 6d., and North-Eastern Steel Company at £5,400. 2s. 6d. The surveyor added that the tenders are extremely low, and it is in the interest of the Council to accept one at an early date. The lowest tender is £4. 17s. per ton for rails, against £5. 18s. 6d. per ton paid for the last work, and all the other items are proportionately low, the total saving working out at upwards of £950.

BUSINESS NOTES.

TRACTION.

Chesterfield.—A proposal to poll the ratepayers on the question of Sunday running was defeated.

Glasgow.—The Corporation have approved of the extensions, for which sanction is to be sought.

Wolverhampton.—It is reported that the Hampton-road route is to be reopened as far as Hunter-street.

Prestwich.—The line from the Grand Lodge to Heaton Park Station is expected to be opened to-day.

Colchester.—An extension of the Corporation tramways, estimated to cost about £8,000, has been decided upon.

Kilmarnock.—The Corporation tramways were opened on Saturday, and a full account appears in another column.

Bradford.—During the past year 250,000 parcels have been carried on the trams, yielding an income of upwards of £1,000.

Bath.—The Tramways Committee recommend the Corporation not to sanction the company's proposed extension along Westgate-street.

Liverpool.—The Corporation have decided to promote a Bill for the construction of tramways in Walton, West Derby, Fazakerley, and West Derby rural.

Wigan.—The Board of Trade have sanctioned running on the line between Ince and the Royal Hotel. So far negotiations with Hindley have not been completed.

Croydon.—A proposal to delete the Upper Norwood route from the Corporation's Bill, on the ground of expense and unpopularity in the neighbourhood, was negatived.

Leith.—The Corporation have decided, before settling estimates, to make enquiries of contractors and of other towns as to their experience with the motors for the cars.

South Shields.—The Tramway Committee recommend that tenders be invited for laying the track in Fowler-street and other sections where work can be proceeded with forthwith.

Proposed Light Railway.—Application is to be made to the Light Railway Commissioners for power to construct a light railway, to be worked by electricity or other motive power, between Warrington and Knutsford.

Bootle.—The Town Council have decided to oppose the Liverpool Corporation's scheme for running trams into Bootle. Each of these authorities is desirous that the parish of Orrel shall be incorporated within its area.

Kirkcaldy.—The Tramways Committee have given a general approval to heads of an agreement for through running between the Corporation lines and a system from Leven, which a private undertaker contemplates constructing.

Spen Valley.—After running only a reduced service of cars in and out of Heckmondwike for about four months, owing to a disagreement with the District Council as to the price to be paid for extra current required, the traction company on Saturday resumed a full service.

Salford.—At last week's meeting of the Council the Chairman of the Tramways Committee, replying to a member, stated that the committee had no objection to publishing the weekly returns for the information of members, whether they were members of the committee or not.

Tranent.—At a meeting of Tranent Burgh Commissioners, a letter from the National Electric Construction Company was laid before them enquiring if they would favourably entertain a proposal to extend the electric tramways from Leavenhall to Tranent. It was unanimously decide to approve the proposal.

Walsall.—At last week's meeting of the Town Council it was stated that the tramway profits to the end of the year were estimated at £6,000. Apparently ½d. fares have answered well, and the Council are disposed to give favourable consideration to an application that has been received for additional ½d. stages.

Swansea.—The town clerk has issued to members of the Corporation notice of a special meeting to sanction a Bill which will provide, *inter alia*, for the acquisition of the Swansea Tramways Company's system, with powers to extend same. At this meeting the position of the Corporation is to be fully explained.

Cardiff.—The Corporation have referred back to committee the scheme of revised fares, which comprises considerable increases. A section of the Corporation considered that the present fares were quite high enough as compared with other towns, and one councillor suggested the introduction of ½d. stages.

Heywood.—From the report of last week's meeting of the Town Council it appears probable that terms will be arranged whereby Heywood will run steam cars over the Rochdale and Bury lines, the latter running their electric cars over the Heywood system. Negotiations for the construction and working of the Heywood lines electrically appear to have dropped.

Sunderland.—The following figures were given at a meeting of the Tramways Committee: for the month of November the returns were as follows—passengers, 1,122,590; mileage, 121,359; receipts, £4,667. 6s. 1d.; receipts per car mile, 9·2d. Compared with November, 1903, there is an increase of 64,937 passengers, 10,116 miles, and £259. 17s. 4½d. in receipts. The takings per car mile, however, show a slight decrease.

Leicester.—November was the first complete month during which the tramways of the town—except one uncompleted route—have been served wholly by electric cars, and the passengers reached a total of 1,718,802. This is a good showin for an unfavourable month like November. During the week ending the 3rd inst. 390,280 passengers were carried. The Groby-road route will probably be completed early in the new year.

Ayr.—It has been decided to proceed with the extension of loops in Carrick-road and at Chapel-park at a cost of about £650. A request from the Prestwick Town Council that the terminus should be at a point south of the Cross was referred to the convener and manager, with powers. The Council have approved the manager's experiment in regard to a new department of the parcel express to convey workmen's dinners along the Prestwick route.

London Tramway Improvements.—The Improvements Committee of the County Council recommend an expenditure on capital account up to £320,000 for street widenings in respect of the tramways sanctioned by the Tramways and Improvements Act, 1904. These are the tramways from Lordship-lane to Forest Hill, Lewisham High-road to Forest Hill, New Cross-road to Lee Green, Catford to Greenwich, and Beresford-square to the county boundary.

Newcastle.—The report issued to members of the Tramways Committee on the accounts from March 25 to Sept. 29 last by the Corporation auditor (Mr. Thomas Bowden) states that rolling-stock should be adjusted by the writing off to revenue of such expenditure under this head as cannot reasonably be considered to have increased the value of the asset, and he also mentions that beyond the depreciation represented by the repayment of loans, no provision has been made under this head.

Wolverhampton.—The accounts of the Corporation tramways for the six months ending Sept. 30 show total receipts of £18,678. 7s. 7½d., against £12,460. 17s. 11d. in the corresponding period of last year. The receipts per car mile work out at 11·85d. A profit of £1,442 for the six months is shown, against a loss of £262 last year. This great improvement is apparently attributable to reduced operating costs, the figure under this head having descended from 5·08d. to 4·72d. per car mile.

Perth.—At a meeting of the Town Council on Monday, a discussion took place as to why the £5,000 estimated to be spent on the construction of the tramways with the Dunkeld-road had not been included by the Finance Committee in their recommendation to borrow £45,000 for the reconstruction of the present system. It was pointed out that the Council had not yet agreed to go on with this section of the undertaking. The Tramways Committee are to deal with this question at an early date. The Finance Committee's recommendation to borrow £45,000 was agreed to.

Ashton.—At the meeting of the Town Council the deadlock between the Corporation and the Joint Tramways Board was again discussed. Mr. Hallam, the chairman of the Tramways Committee, said that the last proposals submitted to the Corporation were such that they could not entertain them. The Ashton sub-committee had suggested other proposals, which included alternate running between Stalybridge and Ashton, Ashton and Dukinfield, and through cars from Mossley to Ashton and Hyde to Ashton. They hoped that in the interests of the public these counter proposals would be agreed to.

Aberavon.—A company has been formed, under the title of the Aberavon District Tramways Syndicate, Limited, to apply for powers authorising the construction of an electric tramway in the parishes of Aberavon and Margam. The matter was discussed at a meeting of the Margam Council, when it was reported that the proposed tramways would run along the main road from the boundary on Aberavon Bridge to the Lady Charlotte-road junction; from the Forge-road and main road junction along the Council's road in front of the Grugos and Curwen terraces, to terminate at a generating station to be erected on the site of the Old Margam works. The matter was referred to committee.

North-Eastern Railway.—At a largely-attended public meeting the following resolution was passed: "That this large and influential meeting of residents on the route of the electrified portion of the North-Eastern Railway protests strongly against the manner in which the North-Eastern Railway Company is treating its passholders and the travelling public, and urgently requests the directors of the company to immediately take steps to improve matters, so that accommodation equal to that in existence before the era of electric trains may be assured, failing which, representations be made to Parliament, and to the Railway Commissioners, and that a guarantee fund be opened, and that a copy of this resolution be forwarded to each of the directors." A fund has been opened. Petrol-electric cars have superseded steam trains on the line from Bellingham to Port Clarence.

Ashton-Stalybridge.—At the monthly meeting of the Stalybridge Town Council on Tuesday night there was considerable discussion about the new joint tramways and the deadlock between Ashton and Stalybridge as to inter-running powers. One councillor criticised the tramways system as a whole, and said that people were getting dissatisfied all round, and that they were losing a lot of money every week. He asked the chairman how soon there was likely to be an agreement between Ashton and Stalybridge. Mr. Alderman Ridyard, the chairman of the Joint Tramways Board, said he wished he could answer the question. They had offered to Ashton similar terms to those which applied between Manchester and Ashton, but Ashton had not accepted their proposal. He had suggested that they should invite Mr. Boyle, the chairman of the Manchester Tramways Committee, with Mr. McElroy (the manager) to preside over the next conference, but Ashton would not agree.

Kettering.—A communication was read at the meeting of the Rural District Council from the British Electric Traction Company, Limited, with regard to the Wellingborough and district tramroad and electricity supply. The company stated that they were applying to Parliament to extend the time for constructing the authorised tramroads between Wellingborough and Raunds *via* Higham Ferrers, and for powers to abandon those running through Finedon and Irthling-

Digitized by Google

borough, as well as a part of those in Rushden. With this application they were also applying for powers to supply electrical energy in bulk, and for power purposes within a considerable area, including the area of the Council, and they hoped by uniting the two schemes to be able to give the public the travelling facilities that were required, and at the same time to meet the urgent need of a cheap supply of power throughout the district. In this they were working in conjunction with the County of Northampton Electric Power and Traction Company, Limited, and they asked the support of the Council to the scheme. They proposed to have a central generating station, with sub-stations in different portions of the area, and to connect these thoroughly, so that they might be in a position to give a supply wherever required throughout the area. The matter was referred to committee.

Ayr.—We have received the following particulars of the working of the tramways for the year ending May 15: gross capital expenditure, £77,259; mileage of track—single, 3 miles 5 furlongs; double, 2 miles—total, 7 miles 5 furlongs; population, 33,000; traffic revenue, £13,957; total revenue, £14,328; working expenses, £7,621; interest on capital, £2,298; sinking fund, £891; net balance carried to depreciation, renewal, and reserve accounts, £3,518; car miles, 353,945; passengers carried, 3,316,380; total number of units used, 324,157; number of units used per car mile, ·91; average number of cars in use for 13 hours per day, 10; percentage of working expenses to receipts, 53 per cent.; average traffic revenue per car mile, 9·46d.; average traffic revenue per mile of single track, £1,830; average total revenue per car mile, 9·71d.; average car miles per day per car, 97; average speed per hour, 8; average car hours per day, 13; average working expenses per car mile, exluding power cost, 3·97d.; average working expenses per car mile, including power cost, 5·16d.; average fare charged per mile, ½d.; average fare paid per passenger, 1d.; average number of passenger per car mile, 9·36; average journeys per head of population per annum, 100; number of cars in stock, 17; total amount of sinking fund, etc., £2,163. 4s. 11d.; amount applied in reduction of debt, £1,665. 15s. 6d.; amount of reserve or renewals fund, £2,931. 7s. 4d.; amount of depreciation fund, £5,484. 15s. 4d.

Musselburgh.—The tramways and electricity works were formally inaugurated on Monday. The tramways will extend from the terminus of the Edinburgh cable system at Joppa on the west to Levenhall on the east, a distance of just over three miles. The track is double for two thirds of the distance—namely, between Joppa and the New Stone Bridge, Musselburgh, and between Musselburgh Town Hall and Loretto—and there are convenient loops where the track is single. The system is the overhead trolley. For the whole distance the fare will be 2d. There are several 1d. stages, and two stages of ½d. each in Musselburgh and Fisherrow. Workmen's fares will be half price, and workmen's cars will be liberally provided morning and evening. There was a large gathering at the inaugural ceremony, including the provost and members of the Town Council; Mr. R. Stewart Bain, chairman of the National Electric Construction Company; Messrs. J. T. Jervis, B. Bernheim, and W. Herbert Fowler (directors), and Mr. W. B. Cownie (general manager and secretary of the company); Mr. M. Buchan, of Buchan and Hogarth, Edinburgh, consulting engineers for the undertaking; and Mr. J. E. Pitcairn, manager of the Edinburgh and District Tramways Company. Mr. Stewart Bain, in a short speech, hoped that the tramways would bring prosperity to the town, and that they would soon extend, not only through Musselburgh, but along the beautiful coast in the district. The National Electric Construction Company was grateful for the support it had received from the provost and Council. He then presented souvenirs to the wives of some of the councillors. Already the demand for electric current for lighting purposes is equivalent to 4,000 8-c.p. lamps. A number of other speeches followed. The service was then formally opened. The National Electric Construction Company, owners of the system, have completed it with great expedition, as a start was not made until May. In the evening the company gave a dinner, which was attended by a numerous party.

Raworth's Traction Patents.—A company has been formed under the title of "Raworth's Traction Patents, Limited," to acquire the British patents granted to Mr. J. S. Raworth for his system of automatic regenerative control for electrically-propelled vehicles and for the demi-car. The capital is to consist of 15 000 preferred ordinary shares of £1, and a similar number of deferred ordinary shares at the same price, of which the whole of the first-named stock is offered for subscription. The vendor takes the deferred shares, and cash to the amount of £3,600. The general principles of the inventions to be worked are succinctly defined in the prospectus as: "(1) To provide a motor for use upon an electrically-driven tramway car or railway train which utilises the impetus of the car either when descending a gradient or when reducing speed to regenerate electrical energy which passes back to the trolley wire. (2) To provide an electrical tramway car which, while complying with Board of Trade requirements, is suitable for working by one man only." The policy of the company will be to carry out conversions of existing cars for regenerative control by their own staff, and to grant licenses to the principal electrical manufacturing companies on equitable terms. The demi-car, which is principally applicable to the numerous lines on which the traffic is light and the profits are small, is designed to save half the labour and half the energy required by a large car. Cars to the number of 15 have already been equipped under these patents for various English tramways, and 65 more are on order. Besides these, negotiations for several other orders from corporations and companies are in an advanced stage. The company will have the benefit of improvements to the patents. Letters patent for the system of regenerative control have been granted to Mr. Raworth in the United States of America, and the certificate of allowance has been issued in Germany. Mr. Raworth will act as managing director of the company for the present. In our issue of July 29 appears an account of a trial of the system. Recently, the secretary of the company, Mr. J. I. Hall, read a paper upon the Raworth system of regenerative control before the Tramways and Light Railways Association, when the reception it met with was generally favourable. During the week new installations of regenerative control have been made at Birmingham, Bournemouth, and Havre, in each case with a pattern of motor which has not previously been tried—viz., Brush 1,002 B, Westinghouse 49 B, and G.E. 1,000. An order has also been received to fit up a car for the Corporation of West Ham.

London County Council.—The agenda of the Council's meeting on Tuesday contained a recommendation by the Highways Committee that a supplemental grant of £500 be made in connection with top covers for the cars, this sum including extra work intended to enlarge the usefulness of the covers. The covers have proved so successful that the committee recommend that another 100 cars be similarly fitted, at an estimated cost of £8,500, the work to be done by the Council's staff. The receipts from April 1 to the 3rd inst. amount to £452,688, as against £354,824 last year. The Highways Committee recommend that the amended plans of the Baker-street and Waterloo Railway in regard to the entrances and exits at Baker-street, Kennington-road, and the Elephant and Castle be approved. At yesterday's meeting of the Court of Common Council at the Guildhall, Alderman Sir John Bell presented a petition from the ratepayers asking the Corporation not to give its assent to the proposal of the County Council to run tramways along the Victoria-embankment. A resolution was read from the precinct of St. Ann, Blackfriars, approving of the proposal, providing that the suggestion for widening the north-western corner of Blackfriars Bridge at the angle opposite the Royal Hotel is carried out. Mr. N. Fortescue moved that the Bridge House Estates Committee be instructed to consider the advisability of widening the north end of Blackfriars Bridge so as to do away with the acute angle which now exists at its junction with the Thames Embankment, and thereby greatly facilitate the traffic at this point. The Streets Committee of the City Corporation have decided to adjourn the further consideration of the proposed line over the Embankment until the new year, in the hope that by that time the report of the Royal Commission on London traffic will be in the hands of the Corporation. The London County Council, by their delegates, have assured the Corporation that they do not propose to take away their veto as the tramway authority in the City, and would be ready to pay any reasonable or proper charge for the use of Blackfriars Bridge. They are also agreeable to the City police having absolute control of the tramway traffic within the City, and would be prepared to maintain the lines and streets in a condition satisfactory to the City authorities. At the Surveyors' Institution, Westminster, evidence has been taken by Major Cardew, sitting as arbitrator, in reference to the claim for £85 813 made by the Woolwich and South-Eastern Tramways Company, Limited, for compensation on the transfer of their system to the County Council. The sum of £25,000, which is included in the claim in respect of street widenings, it was decided to exclude pending a decision in a similar case in the Court of Appeal. Mr. Joseph Kincaid gave details of his valuation of the permanent way at £25,917. He considered the life of the line should be taken at 25 years, which meant that it would have to be relaid at the end of three years from this date. Mr. Hopkins stated that he put the constructional value of the line at £38,225, and after making allowance for depreciation, he considered the present value of the permanent way was £23,051.

LIGHTING AND GENERAL.

Loughborough.—The electrical engineer in his last report stated that 28 applications had been received for the supply of current.

Wrexham.—The Town Council have declined to grant the Telephone Company's application to lay cables for the wires in the streets of Wrexham.

Croydon.—Clause 23, taking power to supply electric fittings and wire houses for the electric light, has been deleted from the Corporation Bill.

Hereford.—The Electric Lighting Committee are buying new positive sets of plates, at £1. 5s. 8d. per set, to be used when overhauling the accumulators.

Larne.—The Larne Electric Light Company have obtained permission to place two transformer tanks under the footpath in Main-street to replace existing transformers on the poles.

Heywood.—The consumption of electricity for the month of October, 1904, was 6,107 units, as against 5,200 units for the corresponding period of last year, showing an increase of 907 units.

Bray.—Consideration of the electrical engineer's report on arc lighting, etc., and a special report by him on present method of charging for current, suggesting a sliding scale, has been postponed.

Sheffield.—Mr. S. E. Fedden, A.M.I.C.E., general manager of the Corporation electricity supply department, has presented to the Council an interesting report dealing with his recent visit to America.

Whitby.—The Urban District Council propose to apply for sanction to borrow £1,000 for electric lighting service lines and meters, and £500 for lamps, there having been applications for 840 c.p. lamps recently.

Inverness.—Messrs. Edmundson's Electricity Corporation, Limited, have presented a petition for the erection of an electric lighting generating station in Waterloo-place, Inverness. The buildings are to cost £4,000.

Greenock.—The Corporation have agreed to increase the electric energy supplied to the tramway company from 500,000 to 600,000 units per annum. The company are to pay for the additional 100,000 at 1½d. per unit.

Broughty Ferry (Dundee).—During November the amount of current generated at the electricity station was 9,302 units, an increase of 410 over the same period last year. It has been decided to lay a new cable at a cost of about £50.

Digitized by Google

Southport.—One of the Corporation public bowling greens has been fitted with electric lights. This is to admit of the game being played after sunset in the winter. If it is successful and popular, other public greens will also be lighted in a similar way.

Paddington Electrical Exhibition.—The Metropolitan Electric Supply Company are organising an exhibition of electrical appliances for lighting, power, heating, etc., to be held at the Paddington Public Baths, Queen's-road. Particulars in another column.

Chilian Electric Tramway and Light Co.—The profit of the lighting departent in Santiago for the month of November is 22,573dol., which makes the total profit of the company for the month 105,351dol., as against 855,597 for November, 1903.

Bournemouth.—The Corporation recently decided to apply to the Postmaster-General for a municipal telephone license. At the meeting of the Town Council on Tuesday, however, it was resolved after a long debate to abandon the scheme, and also to discharge the Telephone Committee.

Galloways, Limited.—The directors have declared a final dividend at the rate of 5 per cent. per annum on the preference shares. Warrants in respect to this dividend and for half-year's interest on the 4 per cent. first mortgage debenture stock of the company will be posted on Dec. 30.

Manchester.—During the past five weeks the call on the Corporation electricity supply has increased to the extent of over 20 per cent. as compared with the corresponding period last year. The increase is confined almost entirely to power and light requirements, demand for the purpose of tramway haulage having practically reached its limit for the present.

East Barnet.—A letter of the North Metropolitan Electrical Power Distribution Company, proposing to undertake the supply of electricity in the district on similar terms to those they have arranged with the Barnet Urban District Council, has been referred to committee. The Council will also interview the Board of Trade with regard to their provisional order.

Louth.—The Electric Lighting Committee recommended on Tuesday the adoption of James-street Mill as the site for a generating station and the approval of the plans prepared by Messrs. Handcock and Dykes. The committee also recommended that steam power be employed to drive the dynamos. An amendment was adopted referring the matter to the Council in committee.

St. Pancras.—Provided the Council agree to the extension of a feeding main into Hawley-road, at an estimated cost of £2,850, the electricity department will be able to give employment to about 45 labourers for a period of three weeks. The work would be commenced about the third week in January next, subject to the price of copper being favourable for placing the contract for the same.

Huddersfield.—In reference to the alleged insufficiency of the telephone service between Milnsbridge and Huddersfield, the secretary of the Chamber of Commerce has ascertained that there are nine lines of communication between Huddersfield and Milnsbridge serving 157 subscribers at Milnsbridge, and that 21 of these have been added since the lines were added between that place and Huddersfield.

Purley.—At a public meeting of the ratepayers in the Purley portion of the parish of Beddington last week a resolution was passed expressing the opinion that the District Council should oppose the application for a provisional order now being promoted by the County of London Electric Supply Company, and should enter into negotiations with the Corporation of Croydon for the supply of electricity in the district of Beddington.

Electrical Weaving.—It is reported that the first electrically-driven weaving shed in the Burnley district, if not in Lancashire, was started on Saturday. It has been built at Heasandford, Burnley, by Messrs. A. Altham, Limited. It will have a complement of 1,600 looms, which will find employment for about 550 operatives. Four hundred looms are now ready for weaving, and the remainder will be started as soon as they can be got ready.

Erith.—To-day has been fixed for the Local Government Board enquiry into the application of the Council for sanction to borrow the further sum of £20,000 for the purposes of the electricity undertaking. The consulting engineers have recommended that an apparatus for softening the crude water and chemically purifying the condensed water should be installed at the works, but before coming to a decision upon this matter have directed an analysis of the well water to be made.

Glasgow.—With reference to the proposal to abolish or modify the minimum annual charge of £2, the Electricity Committee of the Corporation recommend that the charge of £2 be not abolished, but that in all cases where a supply of current is taken for power and lighting purposes by the same consumer, the total amount payable in respect of both supplies should be set off against the annual minimum charge, the arrangement to take effect as from the commencement of the present financial year.

Stock Exchange.—The Stock Exchange Committee have appointed Dec. 21 special settling day for Calcutta Electric Supply Corporation, Limited, further issue of 20,000 ordinary shares of £5 each, £3 paid, Nos. 60,001 to 80,000, and have ordered the said securities to be quoted in the official list. The committee have also been asked to allow Auckland Electric Tramways Company, Limited, further issue of £85,100 5 per cent. first mortgage debenture stock, redeemable, to be quoted in the official list.

Hammersmith.—The premises of 17 additional consumers, representing a maximum of 486 8-c.p. lamps, have been connected to the mains, and six consumers have been disconnected. The present number of consumers taking current from the mains is 1,532. The agreement between the Council and the Society of Motor Manufacturers and Traders, embodying the terms on which the Council agreed to give a supply of electric current to the Olympia, has been exchanged, and the work of laying the cables is now in progress.

Bootle.—On the proceedings of the Electric Lighting Committee coming up for consideration at the last Town Council meeting, it was asked if there could not be a scheme for the payment of the cost of wiring by instalment. Alderman Brewster said there were such facilities, but they were not taken advantage of. The committee would free wire any premises at the request of the landlord, but could not do so for the tenants alone. If a number of tenants got the consent of the landlords, they could have free wiring.

Beckenham.—The officers' reports and the claims by the South Metropolitan Electric Light and Power Company in the sum of £7,897. 2s. in respect of their rights of supplying that part of the district of Beckenham which is covered by the Crystal Palace Electric Lighting Order, 1893, have been submitted to the Electric Lighting and Tramways Committee, who find, having regard to the provisions of the last-named order relating to the purchase by Beckenham, that the company's claim is excessive, and recommend that the matter of price be referred to arbitration.

Tottenham.—At a meeting of the District Council last week the Electricity Committee submitted a recommendation that the Council should accept either proposal "A" or "C" of the North Metropolitan Electric Power Supply Company, noted in a previous issue, for the supply of electricity in bulk or otherwise, but before entering into any agreement the opinion of an independent expert should be obtained on the two proposals as to which would be most advantageous to the district. Finally it was agreed to take expert opinion on "B" and "C," and then to confer with the company.

Worthing.—Alderman Fraser has been appointed chairman of the Electricity Committee for the ensuing year. The Council have offered to recast the charges made for current at the theatre for lighting purposes as follows: in the event of the consumption exceeding 15,000 units per annum a discount of 25 per cent. be allowed off the whole of that consumption; in the event of the consumption not reaching that figure, the rates of discount are to be the same as now in force—viz., 1,000, up to and including 5,000 units per annum, 7½ per cent. discount; over 5,000 and including 10,000 units per annum, 10 per cent. discount.

Eastbourne.—Mr. J. Kempe Brydges, A.M.I.C.E., the borough electrical engineer, in his annual report states that the cost of working the undertaking is being reduced year by year, while on the other hand the use of electricity, both for lighting and motive power, is largely increasing. Some 35½ miles of cable are now laid, the old low-tension cables being rapidly replaced by other of the latest type. The number of units sold last year was 897,193, producing a revenue of £20,240, part of the profit on which has been applied to the reduction of the rates. The Corporation now contemplate the extension of the cables to Willingdon, an inland village adjoining the borough, which is being rapidly developed.

Broxburn and Uphall.—The switching on of the electric light for Broxburn and Uphall took place on Wednesday, Mr. Robert Allan, county councillor, Whitburn, performing the ceremony. The installation has been carried out by Messrs. Drake and Gorham, Glasgow. The main cables measure about 2½ miles, and are laid on the three-wire system. Arc lamps of the Jandus pattern are placed in the main thoroughfares, and these have a total candle-power of 10,200, and in the less busy streets are a number of Nernst lamps giving a total candle-power of 5,125. At the power station there is a Hornsby-Ackroyd oil-engine of 32 h.p., driving a two-pole continuous-current dynamo giving an output of 13·8 kw. Ample provision has been made for extension, and a provisional order has been applied for in order to supply private consumers.

Ludlow.—The Town Council have agreed to consent to the application of Mr. William Norton, 14, Corve-street, Ludlow, for a provisional order to produce, store, and supply electricity in the borough on the conditions that the undertaker agrees: (1) to give the Corporation the option of purchasing the undertaking at the end of the first 20 years, instead of 25 years, as stated in the letter of Nov. 23; (2) to agree that all openings in the streets, etc. (other than the original laying of the cables, etc.), shall be done by the borough surveyor, and shall be paid for by the undertaker on the following terms—up to 10 yards, 10s., over that distance 1s. 6d. per yard; (3) to consult and agree with the Corporation on the position of the cables, feeding boxes, etc., before doing the work; (4) not to construct any overhead wires, etc., without first obtaining the permission of the Corporation; and (5) the price of the current to be charged to the Corporation for the supply to the public buildings, street-lighting, etc., to be 4d. per Board of Trade unit, but should the charge to the general public be reduced to 5d., then the charge to the Corporation to be reduced in like proportion.

Northfleet.—The clerk reported at the last District Council meeting that the town clerk of Gravesend, at a personal interview, had proposed the following compromise of the following points outstanding in the agreement between the Council and the Corporation: (1) As to public lighting—the town clerk suggested that the Council should not be bound to take electricity for any of the public lamps so as to avoid the question of maintaining the light at 100 c.p. at the price stipulated. (2) As to purchase—the town clerk proposed that the Council should allow the 21 years to stand, and not insist upon 14 years if the Corporation did not insist upon the Council paying loss which might be incurred by the Corporation. (3) As to an undertaking that a main should enter the district at the hamlet of Perry-street—the town clerk thought that this could be arranged. After consideration it was decided as follows: (1) As to public lighting—that the Council should be satisfied with the suggestion provided they have an option to accept the terms of the Corporation detailed in the draft agreement. (2) As to purchase—that the Council can neither debar themselves for more than 14 years from acquiring the undertaking, nor pay the loss (if any) which the Corporation may incur.

Digitized by Google

British Electrical Friendly Society.—At the third annual meeting of this society on Monday, Mr. W. G. A. Bond, chairman of the central committee, presided. The report stated that at the close of the financial year there were 1,950 members, and the receipts from all branches (29) amounted to £3,574. During the year 693 members claimed sick pay, amounting to £2,044. The increase of £199 as compared with the sick pay in 1903 was mainly attributable to accidents. The report was adopted, and revised rules to meet the altered conditions consequent on the institution of a pension fund were approved.

St. Marylebone.—The Electric Supply Committee have again appointed Councillor E. R. Debenham chairman of the committee. At last night's meeting the committee recommended that the Council take the necessary steps to oppose the Bills of which parliamentary notice has been given, and any others that may be introduced, so far as the same relate to the supply of electricity in the borough of St. Marylebone, and that Messrs. Sharpe, Parker, and Co. be retained as parliamentary agents for the purpose, and that such counsel be retained and engaged as the Electric Supply Committee, acting on the advice of Messrs. Sharpe, Parker, and Co., may think advisable.

Colchester.—The following statistics are taken from the report of the electrical engineer: output of electricity in units during October, 1904, 91,558 (1903, 43,830; 1902, 28,912); number of consumers at end of October, 576 (387; 300); total number of 8-c.p. lamps connected, 27 681 (24,015; 18,302). The engineer has also reported that he cost of keeping the arc lamps at the electricity station burning all night is rather heavy, and a tender has been accepted for executing the work of supplying and fitting a number of incandescent lamps so as to reduce the expense of lighting by Messrs. Joslins Limited for £225. 10s. One of the engine-drivers is to be solely employed to execute repairs and do all fitters' work.

London Gazette.—The last day for receiving proofs in the estate of Benjamin George Hodges, electrical engineer, 20, St. Luke's-street, Derby, is Dec. 23. The order of the High Court of Justice, Chancery Division, dated Nov. 29, 1904, confirming the reduction of the capital of the Nernst Electric Light, Limited and Reduced, from £320,000 to £90,000, was registered Dec. 6. A meeting of the stockholders of the Blackpool Electric Tramways (South), Limited, will be held on Dec. 22, 1904, at the Law Association Rooms, Cook-street, Liverpool. An adjudication order has been made out *re* William Watson and George Huntingdon, electricians, trading as Watson and Huntingdon, 83, Battersea-rise, London.

Islington.—The Borough Council agree with the London County Council with regard to rating Government telephone wires, and have decided that a communication be addressed to the Postmaster-General asking him to make provision for contributions in lieu of rates to be made to local authorities in London in respect of Post Office telephone wires. Concerning the Bills now being promoted by the Electric Power Development Company and the Charing Cross and Strand Electricity Corporation for the purpose of supplying electrical energy in the London district for use in bulk by existing undertakings and for power purposes, it will be recommended at to-night's meeting that the Council present petitions under seal against the Bills when introduced, with a view to the protection of the interests of the ratepayers.

Swindon.—Councillor A. W. Deacon has been elected chairman of the Electricity Committee for the ensuing year and Councillor J. T. Smith vice-chairman. The town clerk has been instructed to advertise for tenders for carrying out extensions to the generating station. The sub-committee appointed in August to consider as to the desirability of erecting a refuse destructor in connection with the electricity station has been discharged, and the chairman and vice-chairman, and Councillors Mayell and Walters, with the electrical engineer, together with the sub-committees appointed by the Works, etc., Health, etc., and Farm, etc., Committees have been appointed a sub-committee to consider the desirability of the Corporation erecting a refuse destructor, and to report. The coal bunkers at the electricity works are to be covered in, and the borough surveyor is to prepare a plan and estimate of the cost, and obtain tenders from local tradesmen.

Staff Dinner.—To the number of 94, the staff of the Sunderland Corporation electrical department and their friends dined together in the Bells Restaurant on Dec 7 under the presidency of their chief, Mr. J. F. C. Snell. Supporting the chairman were the Mayor (Councillor Foster), the town clerk (Mr. F. M. Bowey), Alderman Bruce, Councillors Dixon, Summerbell, Bell, and Bryers, Dr. Baillie, and Mr. A. R. Dayson (tramways manager). The Mayor, in responding to the toast of "The Mayor and Corporation of Sunderland," said the gathering that night spoke volumes for the mutual confidence which existed in the Corporation electrical department. His Worship paid a high tribute to the services rendered by Alderman Bruce, chairman of the committee, and to Mr. Snell, the electrical engineer. He wound up by expressing on behalf of his fellow-consumers of electric light in the town the hope that the cost of the current would be reduced.

Lowestoft.—The engineer in his last report states that there are now connected to the mains 565 consumers, representing 28,014 8-c.p. lamps. During the month 11 new consumers have been connected, representing 361 8-c.p. lamps. He also reported that he had submitted plan of the proposed method of crossing the harbour with the electric light cables to the Great Eastern Railway Company, but that the company had been unable to approve same. He now suggested that the cables should not be taken across in pipes, but that cables with a helical steel armouring should be laid in the harbour from 6ft. to 10ft. below the bed of the harbour. The report was adopted. We deal with the accepted tenders in another column. The engineer was also instructed to order the cable required for Royal-avenue public lighting, and to report to the next meeting as to the cost of laying a cable for private lighting in the road.

West Hartlepool.—The Town Council have entered into an agreement with the National Telephone Company whereby, in return for permission to lay underground wires, the company undertakes to effect certain reductions in the charges to subscribers. The reduced rates will be applicable to all present, as well as future, subscribers, and any existing subscriber will be at liberty to cancel the existing agreement, and avail himself of the new agreement by giving to the company 14 days' notice in writing prior to the next date for which payment of rental is due. The rates are a uniform charge of £8 for the first instrument and £6. 16s. for the second, additional connections to be available to any member of the firm having the first connection; £7 to cover 1 200 calls per annum (receiving an unlimited number), £6 for 900 calls, and £5 for 600 calls, the calls in excess of this number to be still at the rate of 1d. a call. An enquiry has been held into the application of the Corporation for sanction to borrow the sum of £13,861 for purposes of electric lighting.

East Ham.—The Electric Light and Tramway Committee last week paid a visit to the generating station in order to inspect the extensions recently completed, which consist of a new engine and generator, two 350-h.p. boilers, with condensers, pumps, water purifiers, etc., the total estimated cost of the extensions being nearly £15,000. The chairman of the committee, Alderman J. Savage, started the engine, which was built by Messrs. John Musgrave and Sons, Limited, of Bolton, and supplied by Messrs. Dick, Kerr, and Co., Limited, Preston. It is of the compound vertical type, running at a speed of 100 revolutions per minute, its full load capacity being 1,250 h.p. The total machinery now installed in the station amounts to 3,100 h.p. The boilers duplicate those previously supplied by Messrs. Babcock and Wilcox, who are also the contractors for the condensers, steam-piping, pumps, and water purifiers. The generating station was opened in June, 1901, when it was estimated that at the end of three years there would be a total of 15,000 8-c.p. lamps installed in the district, but owing to the rapid developments and to the cheap rate at which the Council supply current, there are at the present connected 752 consumers, with an equivalent of 29,360 8-c.p. lamps.

Electrical Contractors' Association.—On Friday, Dec. 2, the second annual dinner of the Newcastle branch of the Electrical Contractors' Association (Incorporated), was held at the Continental Restaurant, Newcastle, Mr. Wm. Cross presiding, and Mr. A. Andrews, vice-chairman. There were present as guests, Mr. Harford (Liverpool), Messrs. Giepel and Prescott (West Hartlepool), Mr. W. P. Steinthal (Bradford), Mr. Eugene Brown (Newcastle), Messrs. Gowdy, Usher, and R. Robson (hon. secretary), members of the committee, and other gentlemen. After the usual loyal toasts Mr. Cross proposed "The Association." Mr. Harford replied. Mr. Steinthall proposed "The Newcastle Branch," and Mr. Andrews replied. Mr. Gowdy proposed "The Guests," and Mr. Giepel replied. The Chairman gave a very concise report upon the work of the association during the last year, and the great deal of work the incorporation threw upon the leading members. Mr. Steinthall said he was glad to propose the toast of "The Pioneer Association," and was pleased to see four of the original five members present that evening. Mr. Andrews remarked that the meeting held the evening before was the fiftieth general meeting of the Newcastle Association. Several songs were given during the course of the evening.

London County Council.—The Highways Committee reported on Tuesday that the Council on Nov. 12, 1901, accepted the tenders, amounting to £25,964 and £46,626, of Messrs. Dick, Kerr, and Co., Limited, for the supply of continuous-current plant and three-phase plant respectively, required for the Council's electricity generating stations. The engines in connection with the continuous-current plant had since been installed at the Loughborough generating station, and those in connection with the three-phase plant at the Deptford generating station. Under the terms of the specifications for the engines supplied under each contract, the contractors were entitled to a bonus at the rate of £300 a pound for every pound or fraction of a pound by which the steam consumption of each engine falls short of 24lb. per kilowatt-hour. In order that this might be clearly understood, they pointed out that a generating set produces 21,000 kilowatt-hours per day, or over 7,500,000 kilowatt-hours per year. The saving of 1lb. in steam per kilowatt-hour results in a saving of about 380 tons of coal per annum on each engine. A series of tests had been made with a view to ascertaining the steam consumption of the engines, with the result that the actual consumption was found to be 22·35lb. per kilowatt-hour at full load. This corresponded to a reduction of 1·65lb. per kilowatt-hour on the guarantee required by the specification, and the contractors were accordingly entitled to a bonus of £495 on each of the four engines, making a total of £1,980.

PROVISIONAL PATENTS, 1904.

DEC. 5.

26391. Improvements in mechanism for use in conjunction with apparatus for utilising electromagnetic or "Hertzian" waves. Michael Holroyd Smith, 26, Cambridge-street, Pimlico, London.

26439. A new method for inserting electric light in flowers and foliage, artificial or natural, for use and decoration. Eliza Bickersteth, 24, Ladbroke-grove, London.

26445. Improvements in brushes for electric machines. Victor Isidore Feeny, 60, Queen Victoria-street, London. (Charles Wirt, United States.)

26446. Improvements in and relating to electrical rheostats or resistances. Victor Isidore Feeny, 60, Queen Victoria-street, London. (Charles Wirt, United States.)

Digitized by Google

26449. Improvements in and relating to insulator for electric wires. Samuel Buckner Flynt and Leaman Ambrose Maiden, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

26475. Improvements in electric fire-alarms and thermo-indicators. Alfred Henry McNeil, 40, Chancery-lane, London.

DEC. 6.

26527. Improvements in electric ignition apparatus. August Eckstein and Herbert John Coates, Peel Works, Adelphi, Salford, Manchester.

26529. Improvements in or relating to electric storage batteries. Richard Joseph Crowley and Alfred Blackman, "St. Brelade," Glamorgan-road, Hampton Wick, Middlesex.

26538. Improvements in electrical fuse boxes, ceiling boxes, wall plugs, and the like. Frank Herbert, 104, Clarendon-road, Putney, London. (Complete specification.)

26552. Improvements in lanterns for use in lighting by electricity or gas. Simon Biheller, 1, Great James-street, London.

26557. Improved process and apparatus for the production of metals of the alkali group by electrolysis. Alfred Julius Boult, 111, Hatton-garden, London. (Edgar Arthur Ashcroft, Algeria.)

26582. Improvements in direct-current dynamo-electric machines. Cyril Ernest Davies, 322, High Holborn, London.

26588. Improvements in systems of electrical distribution. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26589. Improvements in and relating to electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26602. Improvements in and apparatus for the production of reactions in gases by means of electric arcs. James Yate Johnson, 47, Lincoln's inn-fields, London. Badische Adilin und Soda Fabrik, Germany.)

26603. Improvements in and apparatus for forming devices for holding or suspending overhead electric conductors or trolley wires and the like. Isaac Everson Winslow, 47, Lincoln's-inn-fields, London.

DEC. 7.

26618. Improvements in and relating to appliances for shifting the points of electric and other tramways or railways. Alexander Taylor, jun., 96, Buchanan-street, Glasgow.

26656. Improvements in electric lamps, said improvements being also applicable to the globes, chimneys, or shades of gas, oil, or other lamps or lights. William Goulton, 114A, Chancery-lane, London.

26679. Improvements in or relating to electric current protecting devices. Walter Schäffer, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, Dec. 9, 1903, being date of application in Germany.) (Complete specification.)

26686. Improvements in electric telegraphs. Siemens Bros. and Co., Limited, and George Sylvester Grimston, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

26696. Improvements in and relating to apparatus for wireless telegraphy or telephony. Simon Eisenstein, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

26699. Improvements in motor-controlling systems. Arthur Clarke Eastwood, 47, Lincoln's-inn-fields, London. (Complete specification.)

DEC. 8.

26704. Improvements in clips for supporting electricity conductors or wires. Arthur Reginald Walmsley, Penny Bank-chambers, Halifax.

26708. Improvements in and relating to automatic starters for electric motors. Charles William Webster, Sunbridge-chambers, Bradford.

26709. Improvements in and relating to fuse or terminal boxes for use in electrical mains or the like. Alfred Sutherland Blackman, Sunbridge-chambers, Bradford.

26748. Improvements in apparatus for controlling telegraphic recorders and other instruments. Marconi's Wireless Telegraph Company, Limited, and Edward Priddle, 24, Southampton-buildings, Chancery-lane, London.

26757. Improvements in signalling bells worked by electrically-controlled compressed air or other gas. Siemens Bros. and Co., Limited, Queen Anne's-chambers, Broadway, Westminster, London. (Siemens und Halske Akt.-Ges., Germany.) (Complete specification.)

26761. Improvements in and relating to electric arc lamps. John Morecraft Wellington and Walter Francis Daniell, 88, Chancery-lane, London.

26772. Improvements in and relating to electromagnetic apparatus. Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (Carl Joseph Schwarze and Amos Martin Kells, United States.) (Complete specification.)

26769. Improved coil trembler for electrical ignition apparatus of high-speed engines for motorcars and similar vehicles. Sidney James Williams, 149, Strand, London.

26786. Improved means for rendering the insulation of electric conductors fireproof. George Gatton Melhuish Hardingham, Clun House, Surrey-street, Strand, London. (Felten und Guilleaume Carlswerk Act.-Ges., Germany.)

26791. Improvements in connections for compounding transformers and like apparatus. Alexander Heyland, 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, Dec. 8, 1903, being date of application in Belgium.) (Complete specification.)

26799. Improvements in holders for electric incandescent lamps. John Cox Dear, 40, Chancery-lane, London.

26805. A new or improved alternating-current electromotor. Frank Michael Lewis, Norfolk House, Norfolk-street, Strand, London.

DEC. 9.

26829. Improvements in electrical switches and cut-outs. Charles Mark Dorman, Reginald Arthur Smith, and Herbert George Bagge, Ordsal Electrical Works, Salford. (Complete specification.)

26849. Improved apparatus for electro-deposition of metals. Bertram Morley Bailey, 77, Colmore-row, Birmingham.

26887. Improvements in three-phase ground detectors. Paul MacGahan, the Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Jan. 20, 1904, being date of application in United States.) (Complete specification.)

26906. Improvements in or connected with electric demand indicators. John Reid Dick and the Reason Manufacturing Company, Limited, Norfolk House, Norfolk-street, Strand, London.

26915. Improvements in electrodes for arc lamps. John Thomas Henry Dempster, 83 Cannon-street, London. (Date applied for under Patents Act, 1901, Dec 10, 1903, being date of application in United States.) (Complete specification.)

26916. Improvements in arc lamp electrodes. Charles Proteus Steinmetz, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 10, 1903, being date of application in United States.) (Complete specification.)

26917. Improvements in electrodes for arc lamps. Willis Rodney Whitney, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 10, 1903, being date of application in United States.) (Complete specification.)

26918. Improvements in arc lamps and electrodes therefor. Johannes Härdén, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 10, 1903, being date of application in United States.) (Complete specification.)

26919. Improvements in arc light electrodes. Johannes Härdén, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 10, 1903, being date of application in United States.) (Complete specification.)

26920. Improvements in arc light electrodes and methods of making the same. Charles Fowler Lindsay, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 10, 1903, being date of application in United States.) (Complete specification.)

26921. Improvements in electrodes for arc lamps and method of making the same. William Stone Weedon, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 10, 1903, being date of application in United States.) (Complete specification.)

26922. Improvements in arc light electrodes. William Stone Weedon, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 10, 1903, being date of application in United States.) (Complete specification.)

26923. Improvements in and relating to electric rheostats. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26925. Improvements in electrical measuring instruments. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

DEC. 10.

26948. Storage batteries. Benjamin Joseph Barnard Mills, 23, Southampton-buildings, Chancery-lane, London. (Thomas Alva Edison, United States.) (Complete specification.)

26957. Improvements in signalling on electric tramways and railways. Charles Henry Pym and Edward James Witcombe, 9, St. Matthew's-road, Cotham, Bristol.

26985. Improvements in and relating to electrical switches. George Page, Alfred Holmes, John Henry Holmes, Leonard William Holmes, and Ellwood Holmes, 1, Queen Victoria-street, London.

26986. Improvements in and relating to electrically-controlled and variable speed gear. Henry Vincent James and Robert Alfred Marples, 1, Queen Victoria-street, London.

26997. Improvements in or relating to telephone apparatus. William Mudd Still and Andrew George Adamson, 46, Lincoln's-inn-fields, London.

Digitized by Google

27009. Improvements in and relating to electromagnets. David Leonard Lindquist, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

27003. Improvements in electric switches. Antoine Bénassy, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 17, 1903, being date of application in Switzerland.) (Complete specification.)

27011. Improvements in vapour electric apparatus. Osias Otto Kruh, 83, Coleman-street, London. Date applied for under Patents Act, 1901, Dec. 12, 1903, being date of application in United States.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 29, 1904.

1903.

18854. Telegraphic recording and perforating apparatus. Armstrong and Orling.

18980. Electrical signalling on railways and tramways. Tunstall.

19063. Electro-capillary detectors, relays, and recording apparatus. Armstrong and Orling.

26465. Systems of electric motor control. The British Thomson-Houston Company, Limited. (General Electric Company.)

27171. Method of insulating electrical coils, conductors, and the like Chitty.

27173. Connector for electric circuits. Kelsey.

27298. Magnetic separators for ores or the like. Dawes.

27512. Electric igniting devices for explosion motors. Treskow.

1904.

456. Manufacture of chlorine by electrolysing sodium chloride solution and apparatus therefor. Leetham and Bousfield.

984. Electrical alarums for clocks. Sturgess.

2455. Control of alternating-current electric motors. British Thomson-Houston Company, Limited. (General Electric Company.)

2581. Machines for making stems for incandescent electric lamps. British Thomson-Houston Company, Limited. (General Electric Company.)

2715. Electric arc lamps. British Thomson-Houston Company, Limited, and Murphy.

3657. Gas or vapour electric lamps. Le Tall. (Cooper Hewitt Electric Company.)

3666. Electric switches. British Thomson-Houston Company, Limited. (General Electric Company.)

8819. Incandescent electric lamp fittings. Löti and Latzko.

15155. Automatic electrical balance. Dworzynski.

18252. Automatic electric telegraphic transmitters. Henn.

18403. Electrolytic process and apparatus therefor. Townsend.

18910. Electrical heaters. Pemberton. (Date applied for under International Convention, Jan. 4, 1904.)

18987. Gas and vapour electric devices for lighting, rectifying, alternating currents, and the like. Thomas. (Date applied for under International Convention, Sept. 4, 1903.)

21402. Electrodes for electric accumulators with invariable electrolyte. Jungner. (Date applied for under International Convention, Oct. 7, 1903.)

22652. Electric circuit breakers. McFeatters and Christmas.

22665. Electric circuit breakers. McFeatters and Christmas.

23009. Intercommunication telephone systems. Birnbaum and White.

23677. Electric tremblers or switches. Aron. (Langumier.)

23820. Electrical choke coils. Carson. (Date applied for under International Convention, March 30, 1904.)

23828. Terminal for electrical apparatus. Prested.

23972. Electrical indicating or measuring instruments having springs to convey the current to a movable system. Siemens Bros. and Co., Limited. (Siemens und Halske, Akt.-Ges.)

24078. Manufacture of single or multiple electric conductors. Soc. Industrielle des Téléphones. (Date applied for under International Convention, March 11, 1904.)

NOTES.

Zurich.—A great scheme is reported for the utilisation electrically of water power at Zürich. It is proposed to construct a barrage of the Sihl with a stone dam 30 yards high, and containing 20,600 cubic yards of masonry, the work to continue as far as the defile of Im Schlagen, and to construct embankments, the result of which would be to form a lake exceeding seven square miles in extent, and containing 96 5 million cubic metres of water, capable of providing force to the extent of 20,000 h.p. for 24 hours daily or 60,000 h.p. for 11 hours daily.

Solar Electricity. — A Portuguese scientist, Prof. Himalaya, claims to have demonstrated that the origin of the sun's heat and rays is electrical. For the purpose of his experiments he designed the "pyrheliophoro," or sun motor, by means of which he is reported to have found that the heat of the sun is more than double that of the electric arc, which has hitherto represented the highest known temperature. It is stated that there is no known substance, not even asbestos, that will not fuse in his sun furnace into which the concentrated rays of his mirror reflector and concentrator are thrown.

The Institution.—Mr. Adams's paper on "The Combination of Dust Destructors and Electricity Works Economically Considered" gave rise to some humorous remarks last week, the author being responsible for one of them. Referring to the electricity latent in the cat, Mr. Adams described it as "electrified pussy"; then, alluding to the number of feline corpses which find their way into the works with the refuse and contribute to the generation of energy, he quoted it as an instance of "pussified electricity." When 9.30 arrived, and there were still several likely speakers, the discussion was adjourned until the 12th prox., when, time permitting, Messrs. Booth and Kershaw will present a paper on "Fuel Economy in Generating Stations."

Rubber Cultivation in Ceylon.—Tests have indicated that rubber can be successfully produced in Ceylon, and several applications have been received for land on which it is desired to cultivate rubber-producing plants experimentally. A notice will be issued very shortly giving full details of the terms and conditions on which Government is prepared for a limited period to lease land at specially low rates for pioneer cultivation. Briefly, these terms are that if the purchaser will undertake to plant the land with rubber, a lease for 50 years will be granted at a minimum rate of 2s. 1d. per acre, or 3s. 4d. per acre if the land is irrigable from a Government tank. Applications for land on these special conditions must be made before a date in next year to be announced, as after that the land will be disposed of in the usual way.

The Jones Underfeed Stoker.—From the *Journal* of the Franklin Institute for the present month we gather that a committee appointed by the institute has investigated the merits of the Jones underfeed stoker, and in consequence has awarded Mr. E. W. Jones, the inventor, the John Scott legacy premium and medal. The wording of the award is that it is made in consequence of the good work done by Mr. Jones in designing his underfeed stoker, and in view of the simplicity of the device from a mechanical standpoint, both in construction and operation. The figures collected by the committee as to the working of the stoker, which is now becoming well known in this country, are exceedingly valuable, and the full report of the committee should be read by all interested in steam raising. The history of the invention is given, but, what is more valuable, there is a series of tables at the end of the report giving actual results obtained from the stoker in four different installations. These speak well of the working of the stoker in extended trials.

A Big Scheme.—A Bill entitled "The Administrative County of London and District Electric Power Company" has just been lodged in the Private Bill Office, and will come before Parliament in the ensuing session. This ambitious project was referred to in our issue of the 2nd inst. The object of the Bill is to incorporate a company with a capital of £5,000,000, in 500,000 shares of £10 each. Messrs. J. H. Armstrong, L. C. Cunliffe, and James Falconer are named as the first directors, while the subscribers include the names of Lord Armstrong, Sir George Taubman Goldie, Sir James Joicey, and the Hon. W. J. Armstrong. The proposed area of supply embraces the city of London, the city of Westminster, the boroughs of Kensington, Battersea, Chelsea, Fulham, Hammersmith, Hampstead, Holborn, Paddington, St. Marylebone, Wandsworth, and Ealing; the urban districts of Acton, Brentford, Chiswick, Hampton, Hampton Wick, Heston and Isleworth, Southall, Norwood, Teddington and Twickenham; the boroughs of Croydon, Kingston-on-Thames, and Richmond, with a number of urban district councils in Surrey, and also Bromley, Beckenham, and Penge in Kent. The area will also include Woolwich, West Ham, Ilford, and Gravesend.

Municipal Loans.—An amusing instance of how far the Local Government Board will sometimes go in absurd details is afforded by the statement of the inspector sent to enquire into the application of the Blackpool Corporation for permission to borrow the sum of £9,000 for the erection of new baths. The inspector was informed that the cost of the electric lamps at the baths would be 1s. each, and that there would be 300 lamps. He stated that in accordance with special instructions from the Board the amount of the loan would be decreased by £15, because these lamps could not last as long as the building. This plan of striking out any items which will not last the full life of the building would, if carried to the extreme, mean the omission of all machinery in a loan for an electric lighting station. It is a well-known fact that the Local Government Board have allowed for the inequality in the lives of the various items by assuming a mean period for the whole. If, then, they are going to strike out items like electric lamps, the mean period should be increased. This, of course, is not an important matter, but the detailed labour involved is, and the Blackburn case shows the futility of the discussion of such small items. The replacement of these lamps would, of course, come out of revenue account, and at the expiration of the term of the loan, presuming the baths were still in use, there would be good lamps in position, so that no financial trouble would ensue.

New Publications.—"Maxwell's Theory of Wireless Telegraphy" (London: Archibald Constable and Co., 10s. 6d.), by H. Poincaré and F. R. Freeland.—The Electric Club *Journal* for December contains articles on "Modern Practice in Switchboard Design," by H W. Peck; "Opportunities of the Apprenticeship Course," by W. M. McFarland; "Electric Railway Braking," by E. H. Dewson. The series of articles on "Applications of Alternating-Current Diagrams" and "Factory Testing of Electrical Machinery" are continued by Messrs. V. Karapetoff and R. G. Workman respectively; and there are articles on shop experience in connection with "Interphase Connections on Two-Phase Generators securing Low Voltages for Starting Induction Motors," "Braking of Armature Leads on Small Armatures"; and "Repairing Pitted Commutators."—"The Central": The issue for November of the organ of the Central Technical College has an

Digitized by Google

illustration of the Manhattan Railway power station as its frontispiece, and Mr. W. A. Delmar contributes a description of the equipment. Prof. H. E. Armstrong continues his articles on "The Mechanism of Combustion," and other subjects dealt with are "The Vacuum Cleaner Machine," by H. C. Booth; "The Colonial Sugar-Refining Company of Australia," by Dr. G. Harker; "Transmission and Distribution of Power to the North-Eastern Railway" (illustrated), by B. Price; and "The Engineer in Egypt," by C. Collingwood.

"Lode" Factor.—There was a long discussion last week at a meeting of the Maidstone Town Council before an agreement was sanctioned with a consumer who will take a large day load from the Corporation mains for driving machinery. The agreement is for 21 years, the rate being 1d. per unit, with a provision that if the price of coal goes up the price for power shall be increased accordingly. The question, however, of this cost as compared with the average cost of production seriously harassed the minds of the Maidstone councillors. It is amusing to note that the local papers look upon the electric lighting undertaking as such a profitable one that they spell the "lode" on the same in the same way as if it was a vein of gold-bearing quartz. We are pleased to see that after the speech of the chairman of the Electricity Committee, the Council decided to sanction the agreement. They afterwards passed a resolution that Mr. Hoadley, the borough electrical engineer, should in future attend all the meetings of the Council in order to explain any technical points that may arise. This will, of course, involve considerable expenditure of time on Mr. Hoadley's part, but from the evidence before us it is clear that it will save a great deal of the councillors' time. Mr. Hoadley would have been able to dispose in a few words of the absurdity of supposing that when the number of units supplied for lighting is equal to the number supplied for power, the day "lode" is equal to the night "lode."

King William's Town.—The Borough Council have decided to municipalise the electric lighting undertaking, inaugurated by the King Electric Lighting Company in September of last year. The Council possessed power to compulsorily acquire the concern at any time up till 1907; after then they could only do so by negotiation, at any rate for a period of 25 years. At the end of 1903 the income was only £194 per month, but in August last it had risen to £453. Out of the latter sum the expenditure amounted to £333, leaving a profit of £120. The Council apparently have the right to acquire the concern at cost price, representing about £21,000. A local journal states that at the present time the business would show a profit of some £300 a month to the Council after allowing 5 per cent. for depreciation, so that there would be a considerable margin after providing for sinking fund and interest. South African finance makes rather different reading from the home level. Thus the Council estimate that they will be able to generate the quantity of electricity now consumed at 11d. per unit, though the further supply which they expect to be called upon to provide will probably cost less than half. This expansion of the business will, the Council anticipate, enable them to supply current at 1s. per unit in response to the representations for a reduced rate which are expected to follow municipalisation. We gather that the inhabitants favour municipalisation, and from the limited data before us the Council appear to have an excellent prospect of making the undertaking a substantial success.

Tramways and Light Railways Association.—A party of this association paid a visit on Friday last to the power stations of the Great Northern and City Railway and the City and South London Railway. An inspection was first made of the former, where the main engine plant consists of four Musgrave vertical cross-compound condensing engines of 1,250 i.h.p., each with standard B.T.H. type generators coupled to the engine shaft and placed between the high and low pressure cylinders. These generators are compound wound to give 575 volts at full load. Each engine is fitted with one Wheeler surface condenser to act in conjunction with same. Two auxiliary generators, driven by high-speed Davey-Paxman engines, supply power for lighting throughout the line. These generators are rated at 120 kw. each, and are compound wound to give the same voltage as the main generators, and the main switchboard is so arranged that the lighting can be run off the traction 'bus bars if necessary. The engineer and traffic manager, Mr. Brousson, accompanied the party, for whom he provided a reserved car on their journey between Moorgate-street and the power station. Subsequently the party were met at Moorgate-street by Mr. Jenkin, manager of the City and South London Railway Company, who conducted them to a special car, where Mr. McMahon, the chief engineer, with his assistants, explained everything. An observation car was provided at the end of the train, and the visitors went over the line, preparatory to inspecting the well-known generating station at Stockwell.

Chemical Action of the Cathode Rays.—Some notes on this subject appear in the *Physikalische Zeitschrift*, by Mr. Emil Bose, and an abstract of same is given in the *Journal* of the Chemical Society. The author remarks that when a very strong potassium hydroxide solution (surface = 200 square centimetres) is exposed in vacuum to the action of a cathode discharge, there are found subsequently in the gaseous phase both hydrogen and oxygen, the volume of the former being considerably more than twice that of the latter. This excess of hydrogen is 10 to 30 times as great as the amount simultaneously produced in a hydrogen voltameter under reduced pressure. The cathode rays, therefore, not only produce an electrochemical effect according to Faraday's laws, but give rise to chemical action in some other way. The most probable source of this is the kinetic energy of the cathode rays, and a computation shows that this is indeed sufficient to produce far greater chemical effects than the electricity carried with the rays, although, of course, a large proportion of the mechanical energy referred to is doubtless transformed into heat directly. That in the experiments described above such a large excess of hydrogen was obtained is due to the greater solubility of oxygen, and the electrolyte was shown in several cases to retain considerable quantities of that gas. Generally speaking, the purely chemical action of the cathode rays is electrochemical; those changes such as the coloration of alkali haloids, which have not been shown to be chemical in character or which can be reversed by the heating action of the rays, are probably dissociation effects due to the dynamic action of the rays. The dynamic action will be still greater than the chemical action in the case of the Becquerel rays.

Long-Distance Telegraphy.—A notable feat in long-distance telegraphy was consummated on Saturday by the establishment of direct automatic Wheatstone working between Liverpool and Teheran, by means of which telegrams for India and the Far East are transmitted 4,000 miles by a single operation, which constitutes by far the greatest extent of line in the world to be so worked. The Indo-European Telegraph Company constructed this route in 1869. In recent years automatic working by the Wheatstone instrument was introduced, the messages being retransmitted several times *en route*. About two years ago the

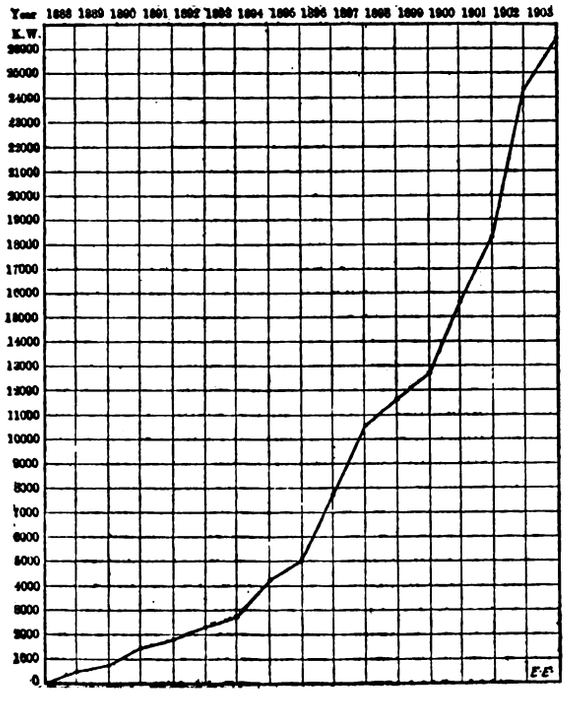
Digitized by Google

company's engineer succeeded, by perfecting delicate instruments, in communicating direct from London to Teheran and eliminating the intermediate stations. Liverpool and Manchester have now been joined up. The current required for working the whole line is of no higher strength than that usually employed, being reinforced by batteries at 12 stages. The large growth of the business of the system and the simplification of its working enabled a reduced tariff to be introduced a few months ago. Another item of news relates to "wireless," which has come to the assistance of the line between Penzance and the Scilly Isles, cable communication having been interrupted. It is stated that as the result of the adoption by the Admiralty of the latest type of Marconi apparatus for use in the Channel Fleet, the "Cæsar," flagship of Vice-Admiral Lord Charles Beresford, equipped with the Marconi system, succeeded in keeping in touch with the Marconi Company's system at Poldhu during practically the whole of the passage home this week from Gibraltar. By this means the Vice-Admiral commanding was able to transmit to the squadron news of the principal events of public interest from day to day. It is expected that the "Victorious," flagship of the second in command of the Channel Fleet, will be fitted with similar improvements to those made in the "Cæsar" wireless installation.

Crystal Palace School of Practical Engineering.—The certificates gained by the students at the Crystal Palace Company's School of Practical Engineering were distributed last Friday at a large meeting, Mr. Charles Hawksley, past-president of the Institution of Civil Engineers, in the chair. The vice-principal, Mr. Maurice Wilson, read the reports of the examiners, which were of a satisfactory character, and the list of awards in the mechanical, civil, and electrical sections of the school. The certification of honour for six certificates obtained in the school course, none lower than third in order of merit, was gained by Mr. J. M. S. Culbertson, and the Wilson premium by Mr. L. H. C. Palmer for a paper on "Railway Practice and Construction in India." The chairman, in the course of his address to the students, said too little credit was given nowadays to the work of the early engineers. They combined with engineering a taste for and a study of architecture. The practice was now very much neglected, and, as a consequence, the structures erected by engineers were too frequently needlessly ugly. The engineers were either wanting in taste themselves or they sacrificed everything to mere utility, and the result was that they disfigured the country in a way that they had no right to disfigure it. A design could be good from the point of view of utility, but it should also result in a structure which, if not handsome, was at least not offensively ugly. He had been much struck with this want of beauty in design, and he proposed, if possible, to establish a premium, in connection with the Institution of Civil Engineers, for designs which combined good taste with utility and strength. Mr. Hawksley then distributed the certificates. A vote of thanks was passed to the examiners: Mr. J. F. J. Reynolds, Mr. C. M. Barnett, and Mr. J. G. W. Aldridge, all old students of the school. The principal, Mr. J. W. Wilson, in the course of a short address, mentioned that when the Japanese Embassy visited this country in 1872 representives were sent to the Crystal Palace School for the purpose of studying their methods of work. They took voluminous notes, and it was very complimentary to know that, when the engineering college was established at Tokio, the Japanese were guided a great deal by what they had seen at the Crystal Palace School.

Telegraph Wires as Returns for Signal Circuits. In a contribution to the *Elektrotechnische Zeitschrift*, A. Prasch describes how he remedied the unsatisfactory working of the station signals on a railway line some 100m. long by making telegraph wires do duty as returns. The original trouble was not due to any inherent defects in the apparatus installed, but entirely to the varying resistance of the earth connections formerly relied upon. This variation was especially noticeable during bright frosty weather. Circumstances prevented immediate recourse being had to the induction system of working, so experiments were made, at first very cautiously, to determine the practicability of using the railway telegraph wires as returns for the station signal circuits. Contrary to expectations, no consequent disturbance could at any time be traced at the Morse telegraph instruments, although elaborate means were taken to detect same, and the two services worked admirably with the telegraph wires doing double duty. However, the practice was not persisted in after the means were forthcoming to adopt another system. Nor does the author suggest the desirability of adopting the principle in general practice. On the contrary, he points out that independent returns are always to be preferred. At the same time, there are occasions when the arrangement in question may be found useful as a temporary expedient, as, for instance, when the existing telegraph poles are already overburdened, or for economical reasons. He goes on to describe, with the aid of diagrams, the way in which the work was carried out in the particular case referred to, and gives the conditions which govern the success of any such arrangement. His conclusions are that if the estimated variation of potential in the telegraph wires, due to the connection of signal wires, is not too great, such connections may be made with impunity, especially as the influence of the telegraph wires on the signal circuits is generally a negligible quantity.

Electricity in Japan.—The accompanying diagram illustrates the growth of central-station electric lighting in



Japan, and has been compiled by the Nippon Denk Kiokwai, the Japanese national electric light association The association was founded in 1892 for the purpose of investigating and reporting on matters of importance to the electric light industry, to represent the industry before the Government, and to popularise electricity and maintain in Tokio a permanent electrical exposition. Only members of the association are allowed to exhibit their goods at the exhibition. All expense connected with the arrangement of

Digitized by Google

exhibits for special electric lighting or for operating machinery is borne by exhibitors. A library is also maintained in the building for the benefit of members of the association. In case of applications for purchase, the authorities in charge of the building offer every facility toward bringing the purchaser in communication with the seller. The total area occupied by one exhibit is not allowed to exceed three cubic feet, and the total weight cannot be over one ton.

Direct-Driven Spinning Frames.—The electrification of cotton-spinning mills is one of the most difficult works that electrical engineers have to undertake, owing to the fact that power has to be distributed over a compact factory, and not over a considerable area. In spite of this, with carefully-designed apparatus, large savings in the coal bill can often be realised. We have recently had brought to our notice by the Alliance Electrical Company some interesting figures obtained from the operation of the mills of the Paley Brake Company, which the Alliance Company have equipped with motors for directly driving the spinning frames. The publication gives an extract of a report on this work by Mr. W. H. Cook, who, we understand, is connected with the spinning company. One difficulty of the conversion was that the speed of the spindles had to be altered at times from 6,000 revolutions to 9,000 revolutions per minute, depending on the different counts being spun. To do this work the Alliance Company designed a motor, which was direct coupled on to the spinning frame by gearing. In other cases the motor was connected to its work by means of belt gear and a countershaft. The purpose of Mr. Cook's test was to see the relative advantages of these two methods of driving. Experimenting first with the direct-coupled motor, he found that when the spindles were run at 6,200 revolutions the motor took 3·2 amperes at 200 volts, corresponding to 0·7 of a brake horse-power. The speed was then increased by stages up to 9,200 revolutions, when the motor took 4·7 amperes at the same voltage, which is equivalent to 1·1 b.h.p. From the plotted observations it was found that the power required to drive the frame increased practically directly as the speed, and not, as has been generally accepted, as the square of the speed. Tests were then made on a frame driven by belting. It was found that to run the countershaft alone ·48 e.h.p. was needed. With straps on the loose pulleys of the frame the power increased to 2·13 e.h.p., which is considerably more than was required to drive two complete frames by the direct-connected method. Mr. Cook concludes from the experiments that at least 50 per cent. of the total power in the mills in question is being wasted through belt-driving. He also speaks highly in favour of the constancy of speed obtained electrically. Figures are given in the report to show the great influence which a loose belt has on the actual spindle speed in a spinning machine. Twelve different frames, which, if the belts were in order, should run at 8,300 revolutions, were tested, and only four out of the 12 had actually got the required speed. Owing to belt slip, there were two machines with spindles running at 7,400 revolutions. With the direct-coupled motor this variation in speed, which means considerable reduction in output, can be uniformly avoided, and there are other advantages which are even more material. We trust that the information in the report will do much to convince other mill engineers of the gain from electrical driving.

The Patent Laws.—At a meeting of the Society of Arts last week, Mr. Alexander Siemens presiding, a paper by Mr. C. D. Abel on "The Patent Laws" was read. The author argued that the system of examination, with power given to the examiners to refuse the grant of a patent on the ground of alleged want of novelty, as carried out by the German and United States Patent Offices and those of many other countries, was detrimental alike to the interests of the inventor and to those of the State. It was an injustice to the inventor to oblige him to go to the expense of an appeal from the decision of a primary examiner. When the views of the examiner differed from those of the inventor, it should be the duty of the former to lay the matter before the higher authorities, and only if these authorities confirmed his decision should the inventor be called upon to argue the case further. This is provided for by the new rules of our Patent Office which come into force with the New Year. The author approved this system, assuming that an adequate examining staff is appointed, and that the most perfect system of classification of the inventions is established for enabling the work of searching to be carried out in a perfectly efficient manner, so that the inventor should not be put to unnecessary trouble in having to prove the novelty of his invention. The carrying out of such an elaborate analysis of all patents, he suggested, would entail a great increase in the examining staff, and, consequently, a very considerable increased expenditure in the Patent Office. The Government would, no doubt, object to this, but he maintained, in view of the great advantages that would be derived therefrom both by inventors and the public generally, that this necessary increased expenditure ought to be insisted upon. There had been a great deal too much false economy practised heretofore by the Government in respect of the Patent Office, for the simple reason that neither the Government nor the public had ever estimated at its true value the great debt this country owed to inventors and their inventions. He suggested that the Patent Office, instead of being, as it now was, a mere branch of a second-rate Government department, should be elevated to the position of an independent Government department directly responsible to the Cabinet and Parliament as constituting the worthy representative of one of the main sources of England's greatness and prosperity. Mr. Siemens criticised our new system on the lines indicated in his recent presidential address before the Institution of Electrical Engineers, holding that the examination ought to be made by the inventor himself, the Patent Office supplying all possible facilities. This, he implied, would obviate a false sense of security. In lighter vein, he remarked that it was easy enough to invent; the people who ought to be rewarded were those who introduced the article commercially. Our impression is that a special staff of examiners is being prepared in view of the new regulations; in fact, this was one of the reasons why the Act of 1902 was made prospective, and we trust that this new staff will attain substantially to the standard of efficiency outlined by Mr. Abel.

Electrical Practice in America.—The Sheffield Corporation authorised the general manager of their electricity supply department, Mr. S. E. Fedden, to visit the St. Louis Exhibition and certain other towns in the United States with a view to ascertaining the most up-to-date electrical appliances. He accordingly participated in the recent Transatlantic tour of the Institution of Civil Engineers, and the impressions he gained are the subject of an admirably prepared and well-illustrated report. Mr. Fedden's comparison of London and New York is interesting. New York's population is 3½ millions; London's is five millions. London's electricity is supplied by 30 authorities; New York's solely by the Edison Company, with the largest generating station in the world. More than 30,000 customers are on the books of the New York company, and the lamps, heaters, motors, etc., connected to the mains are

Digitized by Google

equivalent to 3,068,041 16-c.p. lamps, of which there are over 1½ million incandescent lamps and nearly 21,000 arcs, the annual output according to latest returns being about 130 million units per annum. The whole system is designed on the same general principles as were adopted for the arrangement of the Neepsend works. The underlying idea may be described as one of cellular construction and strict sectionising of the plant, so that starting out with any given generating unit, it and its auxiliary apparatus portion of main cables, etc., might be isolated if desired from the general system and act as a separate and complete station. Mr. Fedden found a great deal to admire in the substantial way in which the electrical distribution of the city of New York has been laid out, no expense being spared in making it as near as possible perfect against breakdown or discontinuity of supply for any lengthened period. The system in Sheffield is laid out on very similar lines, except that as yet Sheffield has not been able to spend nearly so much money in duplicating all the mains to the different sub-stations. Mr. Fedden deals with Niagara, the electrical equipment of canals, and a number of other matters, which we may refer to in future issues, and then gives some general impressions, gained largely from the St. Louis Exhibition After alluding to the great increase in the size of generators and engines, as well as the extended employment of electric motors for the driving of all kinds of machinery, and the very large number of engineers engaged in experimenting with new forms of lamps for use on electricity circuits, all tending to decrease the cost of consumption, Mr. Fedden remarks: "Our own work has made such strides in the last few years that to-day we need fear no comparison with American methods in point of scientific development, and although in the nature of things most of our undertakings are on a smaller scale, there is undoubtedly a high average of excellence to be found in English practice, and greater consideration for the comfort and safety of the general public. Much of the work to be seen in the States is obviously designed to meet as cheaply as possible the demands of the moment." "The general tendency," proceeds Mr. Fedden, "of modern American practice in power generation and distribution is to concentrate the plant at one or two centres, and reap to the full the advantages of large units, and the highest practical limits of steam pressure, voltage, etc." Referring to the experiments carried out by the General Electric Company, Mr. Fedden says it seems most probable that a commercially successful single-phase alternating-current motor for tram and railway work will be on the general market very shortly. If this motor is successful, Mr. Fedden considers that it will pave the way to the gradual change-over of the main-line traffic to electric driving as the present steam locomotives become old and obsolete. Mr. Fedden is evidently a believer in turbines, and thinks there is plenty of room for both the Parsons and the Curtis types. The report shows throughout that Mr. Fedden made good use of his opportunities for observation.

A Three-Wire Railway in Bohemia.—At the recent Vienna convention of the International Street Railway Association Mr. Krizik, of Prague, referred to a 1,400-volt direct-current three-wire railway between Bechyne and Tabor, Bohemia, designed by him recently, of which an account appears in the *Street Railway Journal* The system is 16 miles in length, and the steepest grade is 3 5 per cent. The generating station was located near the terminus at Tabor, so as to supply light to that city and to be in proximity to a good supply of condensing water. Direct-current distribution at 750 volts was considered inadvisable owing to the heavy drop in voltage, and alternating current was rejected on account of higher first cost, lower efficiency on part loads, and lesser utility for the purposes of a combined railway and lighting plant. Owing to the small rail section used and the length of the line it was decided to instal a three-wire 1,400-volt direct-current system, with 700 volts on each side and the rails as a neutral. The power station contains three 120-h.p. compound-condensing engines, using superheated steam at 300deg. C. The engines are belted to direct-current generators, one of which supplies current for the railway only, and the others for both railway and lighting. One of these belted sets, running at 220 revolutions per minute, when

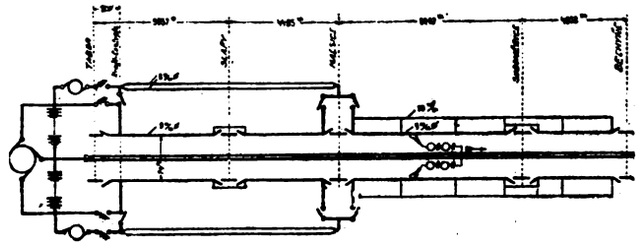


Diagram of Distribution System.

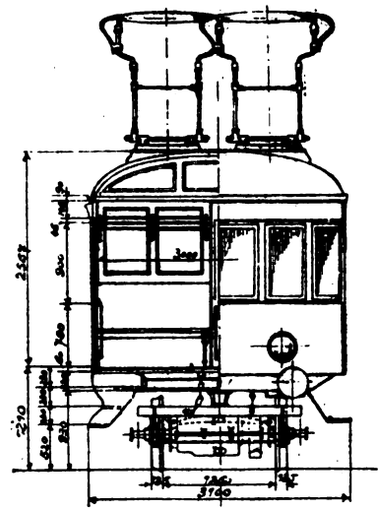
operating with the storage battery is capable of furnishing enough current to operate two 56-ton trains; at other times it is used for lighting purposes. Other sets are installed for emergencies, and two belt-driven boosters are available. The storage battery has a capacity of 123 to 171 ampere-hours for three hours loading or unloading. As half of the motor equipment operates on one side of the circuit and half on the other, the railway system is well balanced, and very little current flows through the neutral. The obvious advantage of the system over a straight line is that under no circumstances can a motor be exposed to more than 700 volts, and no difficulty has been experienced in commutator or motor installation with this pressure. Current



Cross-Section of Car Dimensions in mm.

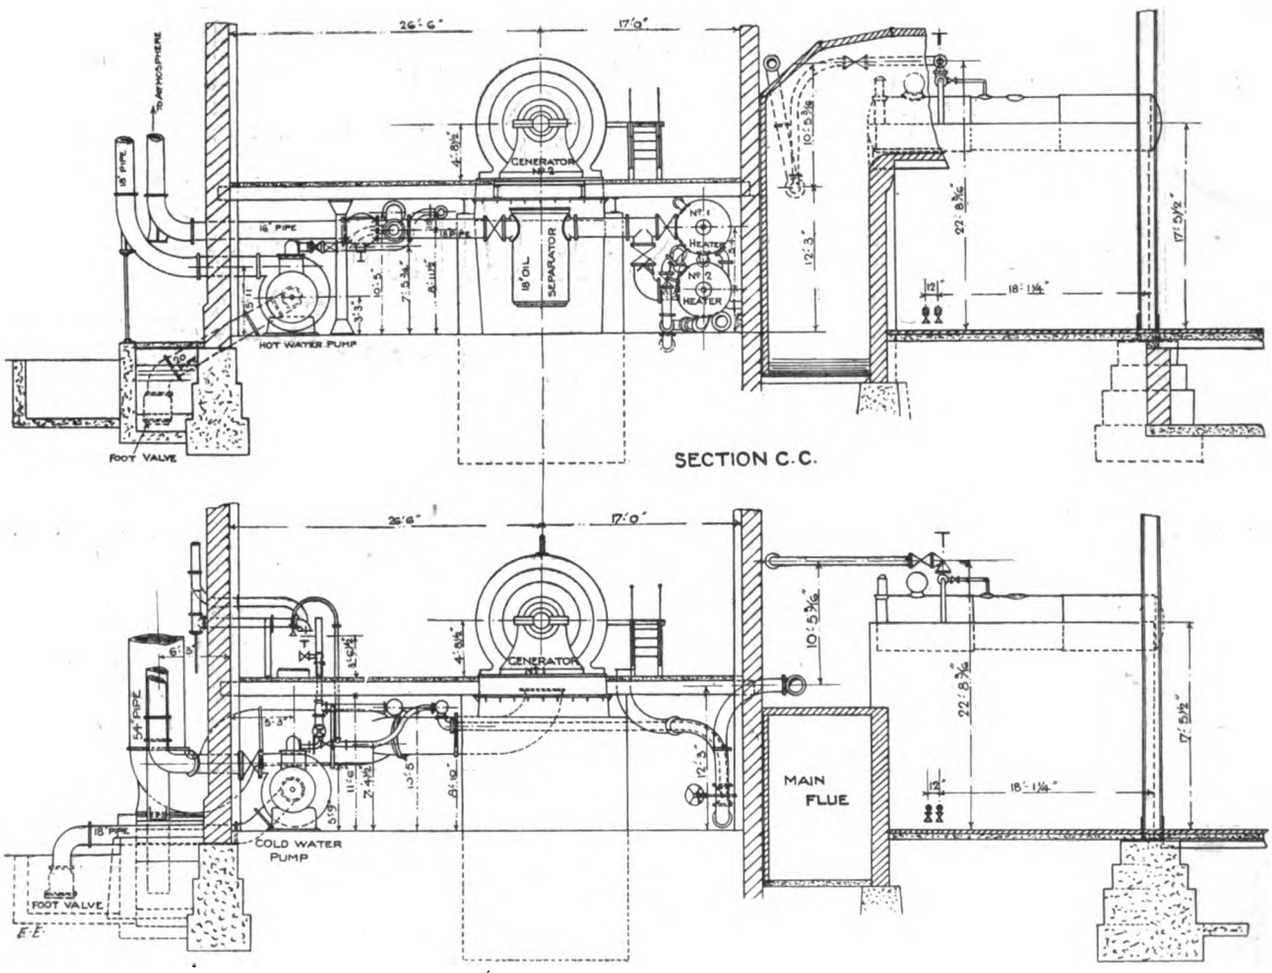
is taken through two bow collectors. Each double-truck motorcar is furnished with four 30-h.p. 650-700-volt motors, running at 550 revolutions per minute. The commutator has 151 bars. The gear ratio is 15 : 75, and the speed attained on the level is 18 miles an hour. At starting, all motors are connected in series, and then two in parallel, but always with an earth connection between the pairs of motors. The resistance has three steps and two running points, with the motors in series and in parallel. There are also two steps for higher speeds obtained by weakening the motor fields by shunt resistances. So satisfactory are the results that a line operating at 3,000 volts and using 800-h.p. locomotives is stated to be in contemplation.

Digitized by Google

load of 184 amperes at 11,000 volts, and the guaranteed efficiency is 96 5 per cent. at full load, 95 5 per cent. at three-quarters, and 93 75 per cent. at half load. The exciting current is, as usual, led to the field coils by the aid of slip-rings. It is derived from the two exciter units, each of which consists of a Westinghouse single-acting compound engine, running at a speed of 275 revolutions per minute, direct coupled to a 100-kw., 125-volt, direct-current compound-wound generator. One such unit is sufficient to supply all the generators when fully loaded with exciting current.

Each turbine has a complete set of auxiliary plant, including an air-pump, a hot and a cold water circulating pump, a barometric condenser, and two cooling towers. The arrangement of these can be seen from the illustrations herewith. Thus, in Fig 3, which goes across two pages of our journal, we show an elevation of the station as it will be when the third set is fixed. The cross-sections of the station (Figs. 4 and 5) help to illustrate the positions of these auxiliaries, and they should be consulted with due reference to Fig. 6, which gives the general plan of the pipework for one set. Fig. 7 is an elevation of the outside wall of the engine-room, showing the barometric condensers, while Fig. 8 gives the details of the cooling towers.

Commencing our description at the point at which the steam leaves the turbines, there are two exhaust openings, owing to the fact that the turbine is of the double-flow type. The steam enters the turbine at the centre, and passes half to the right and half to the left as described above. It is then discharged downwards into two 36in. diameter pipes in the basement. These, as can be seen in Fig. 6, discharge through a breeches piece into the 54in. diameter main, which forms the uptake pipe of the condenser. The condensing plant was also made by the British Westinghouse Company at their Trafford Park works to the designs of the Alberger Condenser Company. This is a form of condenser that until recently was little known in England, but it was chosen because it is particularly adapted to maintaining the high vacuum at all loads that is such an important feature in the economical working of the steam-turbine. The condenser installed for each main generating unit is capable of dealing with 66,500lb. of steam per hour at normal full load and 110,000lb. per hour at maximum overload for a period of one hour. At normal load a vacuum of 27in. is attained, and the above overload reduces this only by 1in. Under the former condition the velocity of the steam at no point exceeds 270ft. per second, or the maximum temperature of the circulating water 85deg. F. The action of the condenser is simple. The steam rises up the vertical 54in. pipe seen in Fig. 7, and at the top passes over into the chamber to the right, where it mixes with the cold injection water. The height of the pipe which then discharges the mixture is such that a barometric vacuum is obtained. The other apparatus required for each unit are thus a cold-water circulating pump, which is



FIGS. 4 AND 5.—Cross-Sections of the Power House, showing Details of Auxiliary Plant.

of the 18in. centrifugal Gwynne type, and a 16in. centrifugal hot-water circulating pump for lifting the hot water from the hot-well and discharging it up to the cooling towers. It will be seen that by making the cold-water pump 2in larger in diameter than the hot-water, and also by making the pipe for discharging the cold water into the condenser 2in. larger than the barometric leg of the same, a seal is always secured. The steam upcast pipe is, however, arranged with an atmospheric relief valve at the top, so that in the event of any trouble with the condenser, relief to atmosphere for the condensed steam is immediately secured. There is also connected to the top of each condenser a steam-driven dry vacuum pump, which can be seen on the floor level in the illustration (Fig. 3). The engine driving this pump when working at full load develops 55 h.p. with a steam consumption of 1,375lb. per hour. By what is termed the two-stage arrangement of this pump it is enabled to effect a vacuum of 29in. in the condenser when this is shut off from the engine. The chief feature of this two-stage method, which has frequently been fully

Digitized by Google

described in the technical Press, is that it makes it possible for the condensing plant to maintain a very high vacuum at all loads, even with a temperature of the circulating water considerably exceeding the normal.

The centrifugal circulating pumps are driven by Westinghouse high-speed compound engines, owing presumably to some variation of speed being required with variations of load, which cannot be so easily obtained with three-phase induction motors. The cooling towers in which the circulating water has its temperature reduced to about 80deg. F. were erected by Messrs. Donat and Co., and are of the Zschocke type. Our illustration (Fig. 8) shows the details of these towers, which are constructed of impregnated wood. There are two towers for each condenser, and each tower is capable of dealing with 400,000 gallons of water per hour. What is termed by the contractor one tower really consists of two independent towers as far as cooling is concerned, because they can be worked in two half sections. Water is delivered at a height 25ft. above the foundations, and the top of the tower is 75ft. The cooling is secured entirely by chimney action, there being no fans for increasing the draught. The water from these cooling towers passes out into the large reservoir lake referred to in our last issue.

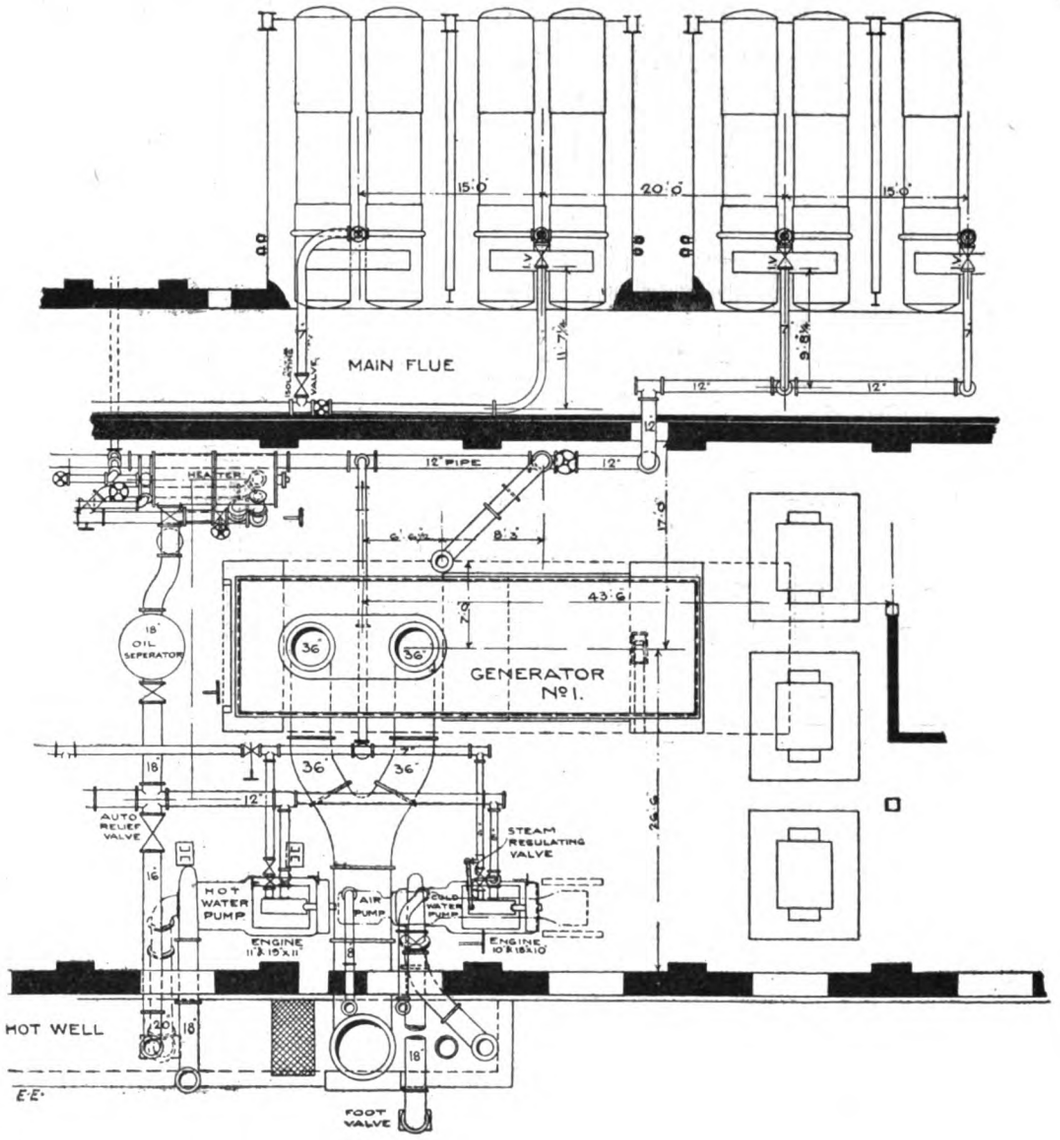


FIG. 6.—Plan of one Turbine, showing Pipe Connections.

The other auxiliary plant employed in the station consists of two surface heaters, each containing 1,000 square feet of heating surface; one Alberger surface condenser of 700 square feet cooling area for condensing the exhaust steam from the exciter engines and the 100-kw. auxiliary generating set; two Cole, Marchent, and Morley grease extractors; two tandem compound Weir steam feed pumps.

We now come to the boiler-room, which also contains many distinctive features. We only show in our fragmentary plan one small portion of the boiler-room, but the details of the boiler can be seen from the section

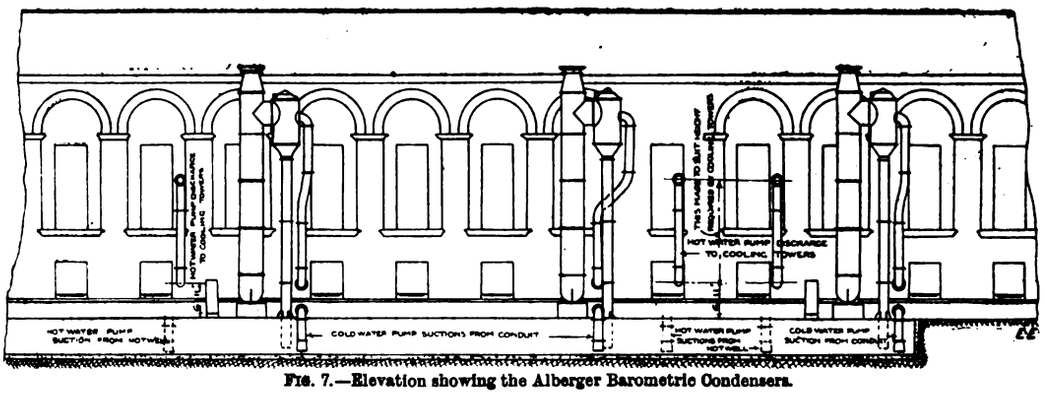

FIG. 7.—Elevation showing the Alberger Barometric Condensers.

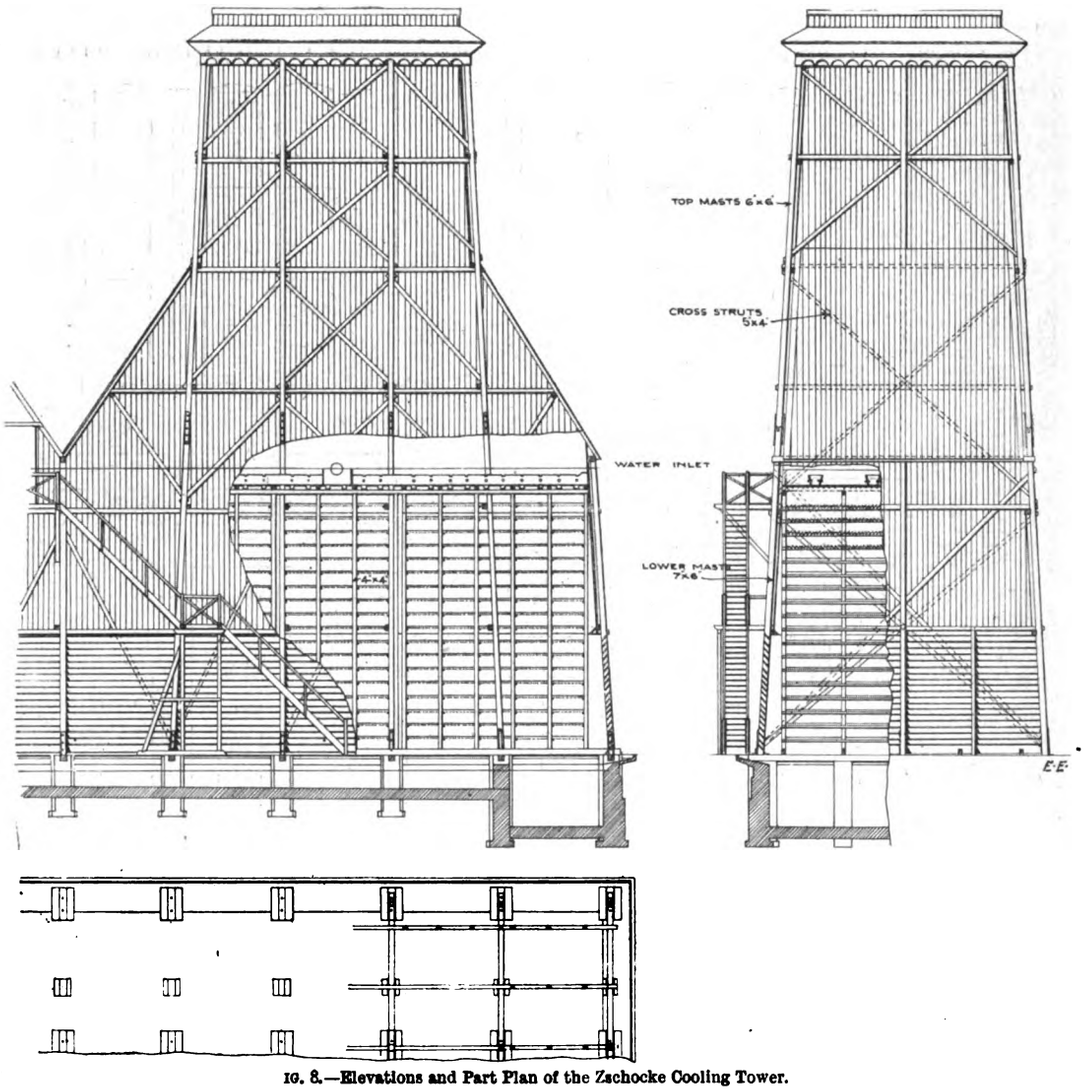
Digitized by Google

(Fig. 9) and from the photograph (Fig. 10), which shows a boiler partially set. Ten Babcock and Wilcox water-tube boilers are already installed at the above station, each of



IG. 8.—Elevations and Part Plan of the Zschocke Cooling Tower.

5,730 square feet heating surface, constructed for working at 160lb. pressure, and each evaporating 20,000lb. of water per hour. These boilers are fitted with Babcock and Wilcox

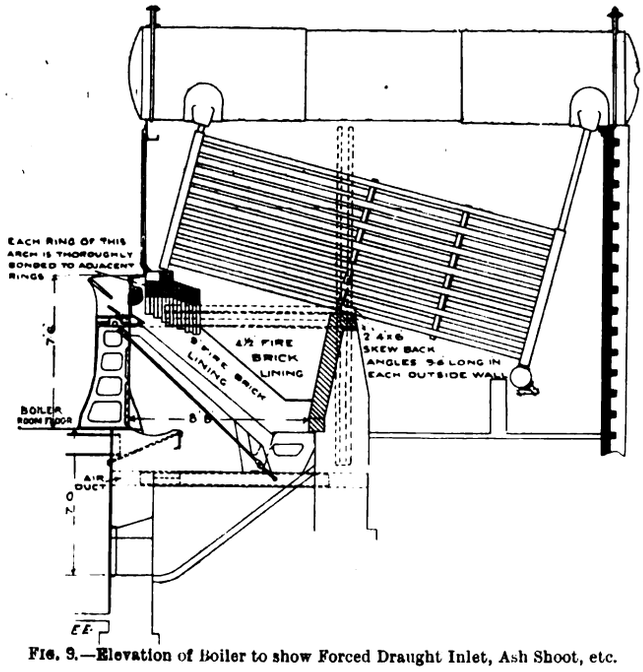


FIG. 9.—Elevation of Boiler to show Forced Draught Inlet, Ash Shoot, etc.

integral superheaters, each of 894 square feet heating surface, which impart 100deg. F. superheat to the steam. There are also on order four additional Babcock and Wilcox boilers of the same heating surface, but constructed for working at 180lb. pressure, and fitted with superheaters imparting 180deg. F. of superheat to the steam. A further description of these boilers is hardly necessary owing to the fact that they find a place in nearly all the largest electric generating stations, and are hence well known to all. It will be noted that only a moderate superheat is asked

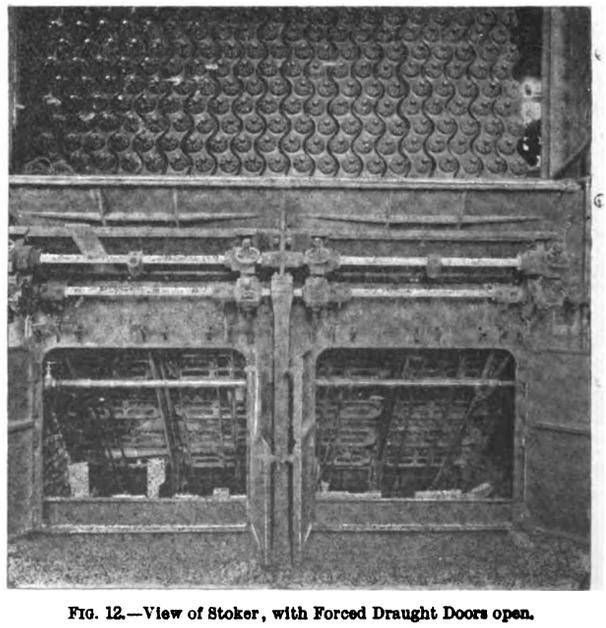

FIG. 12.—View of Stoker, with Forced Draught Doors open.

for, and that in this instance the abnormally high superheat which has given trouble in certain cases is not to be used.

Digitized by Google

The stokers with which these boilers are equipped are of a novel type as far as this country is concerned. They are the invention of an American engineer, Mr. W. R. Roney, but they have been developed by the Westinghouse Company,

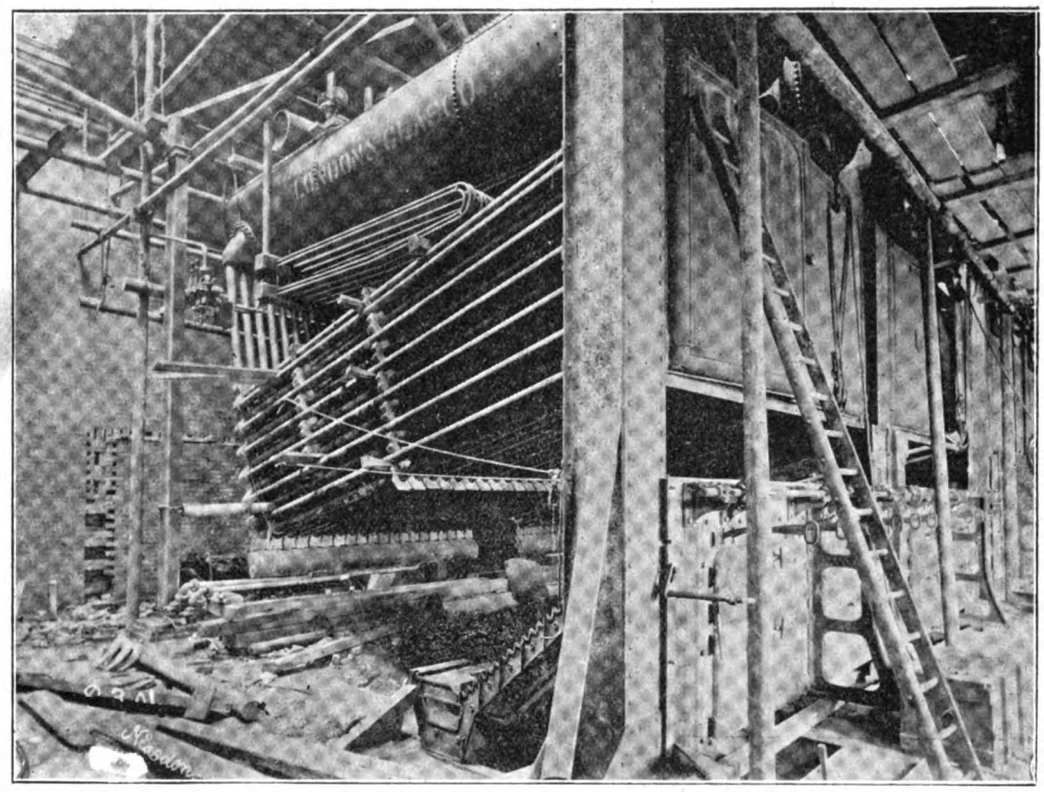

FIG. 10.—View of the Babcock-Willcox Boilers and Superheaters in course of erection.

and used with success in the States for some 10 years. To make the details clear to our readers, we reproduce in Fig. 11 a section of this stoker, while Fig. 12 is a view of the front of a boiler at Neasden. It will be seen from the illustration that the coal passes from the hopper on to a dead plate at the top of the inclined stoker. From there it is fed on to the inclined grates by the reciprocating pusher. The grate bars rock through an arc of 30deg., assuming alternately the stepped and the inclined position. The grate bars receive their motion from rocker bar and connecting rod, and these, with the pusher, are actuated by the agitator, which receives its motion through the eccentric from a shaft attached to the stoker front, under the hopper. The range of motion of the pusher is regulated by the feed wheel from no stroke to full stroke, and the amount of coal pushed into the furnace adjusted according to the demand for steam. The motion of the grate bars is similarly regulated and controlled by the position of the sheath nut and lock nuts on the connecting rod. Each grate bar is composed of two parts—a vertical

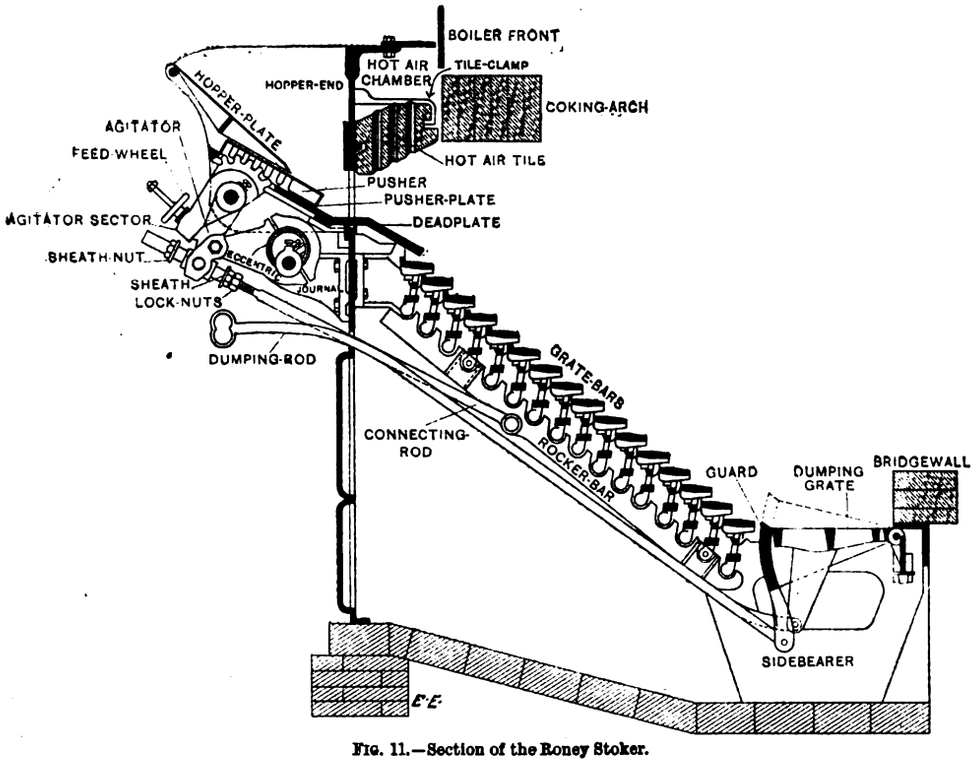

FIG. 11.—Section of the Roney Stoker.

web provided with trunnions at each end, which rest in seats in the side bearers, and a fuel plate, ribbed on its under side, which bolts to the web. These fuel plates carry the bed of burning coal, and being wearing parts, are made detachable, thus reducing cost of repairs to a minimum. The webs are perforated with longitudinal slots so placed

that the condition of the fire can be seen at all times without opening the doors, and free access had to all parts of the grate to assist, when necessary, the removal of clinker. These slots also serve an important purpose in furnishing an abundant supply of air for combustion. The arch over the bed-plate under which the green coal is discharged is kept at a very high temperature, and aids in the combustion of any smoke formed at the point where the fuel enters the furnace, and secures the coking of the coal. It will be seen from the illustrations that these stokers as arranged at Neasden can be used with forced draught, and, if need be, induced draught can also be made use of.

The arrangement for discharging clinker can be readily

Digitized by Google

seen from the illustration. It is claimed by the makers of these stokers that the form of inclined grate gives the fireman more control over his fire, as he can readily see if clinker is forming. It is also stated that with these stokers, with their liberal grate areas, boilers can be forced more readily than is the case with some other types of mechanical stokers. This feature is one which is of the utmost importance in any power-house supplying railways with suburban traffic, where a heavy rush of traffic morning and evening has to be met. The flues from these boilers pass along the side of the boiler-house wall, as seen in Fig. 4, until they are opposite the chimney shaft. The two main flues, one from each direction, then rise, as shown in Figs. 5 and 14, and pass overhead to the economisers. There are two batteries of Green's economisers now fixed, but the plans provide for four batteries being used in the future. Each battery has 1,760 tubes 10ft. long and 4in. in diameter. The by-pass flues, for use when the economisers are being repaired, pass underneath the same, as can be seen in Fig. 14. In Fig. 15 we show the neat arrangement of dampers, by means of which the change from natural to induced draught is made. This plans shows the exits from the four economiser chambers, which discharge into a triangular space in which there are inlets to two fans. The dampers, A and B, when in the position shown in the illustration, close the direct passage for the gases to the chimney, but open the path from the discharge from the fans. By this means, the change from natural to induced draught can be quickly effected after the induced-draught fans have been started up. The elevation (Fig. 16) shows in more detail one of these fans, which are driven by separate steam-engines. The chimney, which is designed to provide for the first portion of the plant now ordered, is 15ft. in diameter and 200ft. high.

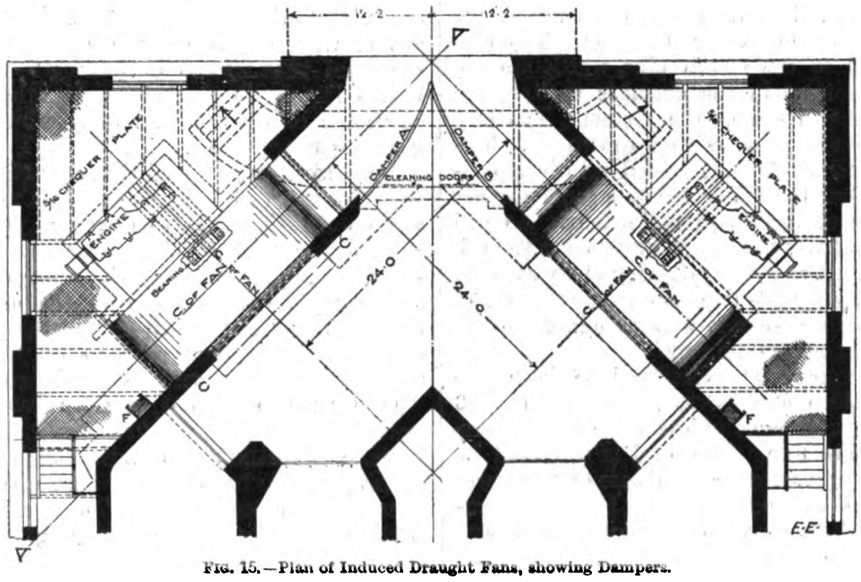

FIG. 15.—Plan of Induced Draught Fans, showing Dampers.

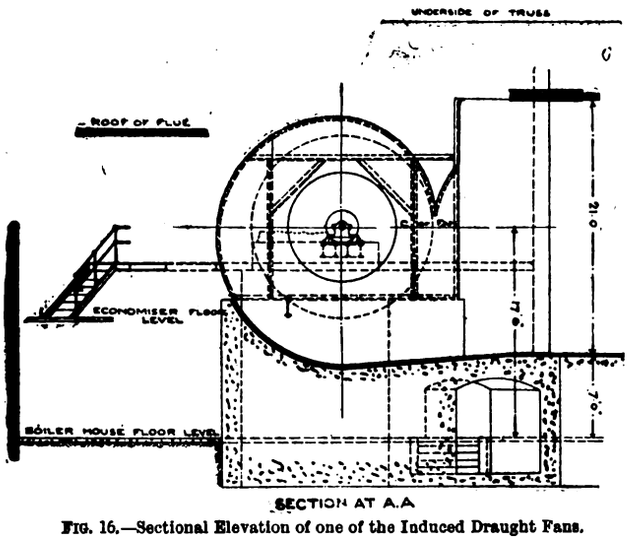

FIG. 16.—Sectional Elevation of one of the Induced Draught Fans.

Another interesting feature at Neasden is the drainage of the steam-pipes, which is effected without any steam-traps or openings to atmosphere. We show in Fig. 17 a diagrammatic elevation of the drain pipes, which are arranged on the Holly system. The usual connections for drainage are made to various points on the steam-pipes

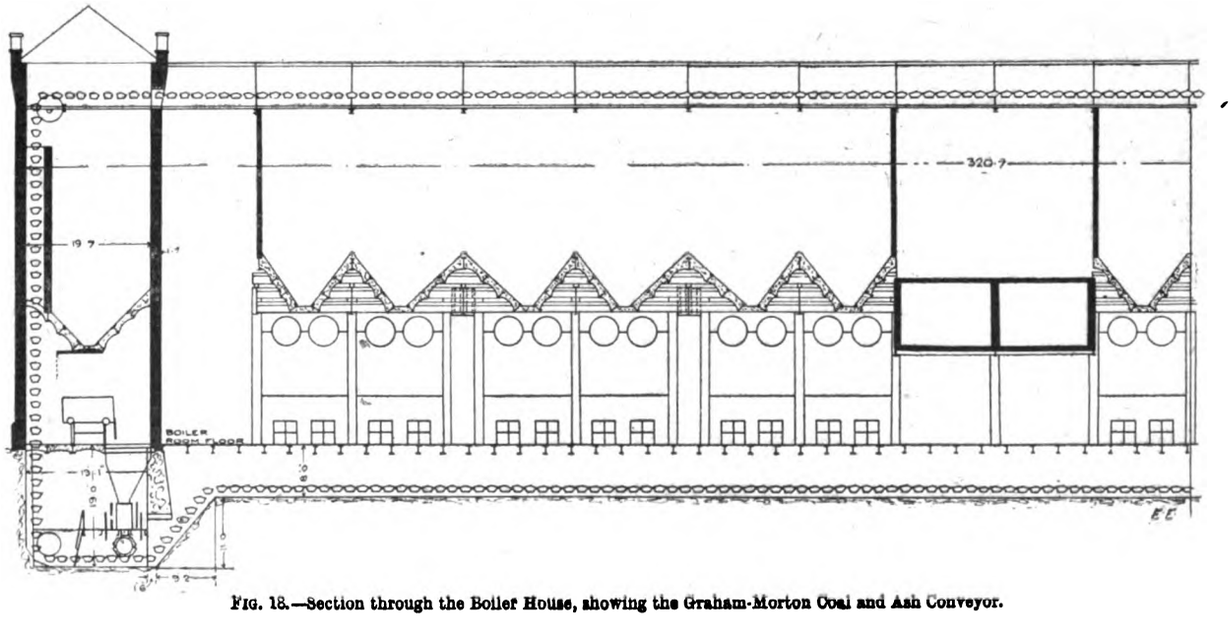

FIG. 18.—Section through the Boiler House, showing the Graham-Morton Coal and Ash Conveyor.

Digitized by Google

in the boiler-room and engine-room. These drain pipes are all carefully lagged, and connected to a receiver at the lowest point of the system. From there an 1½in. diameter rising pipe, also carefully lagged, is led to the top of the building, where a discharge chamber is erected. The condensation in this and in the return pipe, which are not covered, causes the pressure in the chamber to be lower than that at any other point in the system. The condensed water in the drain pipes is thus drawn up. The head of condenser water in the long cooled return pipe is then enough to overcome the difference in steam pressure between the discharge chamber and the boilers. As will be gathered from the above, the whole system has the full boiler pressure on it. The device is giving every satisfaction, and it avoids any trouble due to uncertain action of steam-traps. This Holly system is also introduced to this country by the Westinghouse Company.

The coaling arrangements at Neasden have been provided by Messrs. Graham and Morton, Limited. Fig. 18 shows the general arrangement of the large bucket conveyor provided by this firm. The coal is delivered by railway trucks into a large copper at the base of the tower at the eastern end of the boiler-house. It then passes through crushers which break it to the required size and load the broken coal into the bucket conveyor, shown in the illustration. It is elevated to the top of the building and discharged into the self-trimming bunkers over the boiler-room. The coal is weighed on its way to these bunkers, and there is also a weighing machine in each shute from the bunkers to the hoppers of the mechanical stokers. When ashes have to be removed, they are dropped into the bucket conveyor as it passes to the basement and then elevated and discharged into the large bin, which is shown in the tower in Fig. 18. In this way a coal-truck, after having discharged its load into the coal-crushing hopper, can be filled up with ashes.

(To be continued.)

HIGH-TENSION SWITCHGEAR.

Mr. Leonard Andrews's paper on the above at the Manchester Section meeting of the 13th was taken as read in order that the discussion might benefit. As, however, the "few general remarks" made by the author took over an hour and a half to deliver, the discussion was shorter than expected. The point principally emphasised by the author was naturally the suitability of the reverse-current discriminating cut-out, with which Mr. Andrews is identified, for general use on switchboards where there is a possibility of a faulty generator imperilling an electricity supply system. Mr. Andrews's address was copiously illustrated by experiments upon various types of discriminating cut-outs which were fitted up on the local lighting circuit, and a full size section of a 6,600-volt switchboard of Cowans make was also displayed. Most of these experiments worked as expected, and some provided comic relief by missing their cues, which is what is to be expected at this period of the year.

Mr. WOODBRIDGE, in opening the discussion, reviewed the actual conditions under which reverse-current circuit breakers required to work, and considered that they should not be used, but that the generators should be solidly connected to the bus' bars. He pointed out that the difference between phase relation and current would alter for every ease. The switchboard attendant was the best discriminating cut-out in his opinion.

Mr. CLOTHIER thought the sample switchboard on view would be all right for the voltage if built on the scale of 6in. = 1ft., but would prefer to work it at 2,000 volts himself. He wished to know its cost per kilowatt dealt with, and stated that the Carville board cost about £2 per kilowatt. He described Mr. Andrews as the "electrical handcuff king," who made a practice of tying himself up in knots for the purpose of showing how skilfully he could extricate himself. Mr. Andrews had made a study of discriminating cut-outs for the past 12 years, and was now *au fait* on the subject, but he did not think that the run of station engineers understood much about them, and believed that Mr. Andrews had not yet met with all the obstructions that would be discovered in the path of the device. These cut-outs did not prevent shorts on the switchboard itself, and he suggested that instead of putting in expensive duplicate boards for use in case of trouble, the feeders should be connected to the machines direct through a simple plug shunting arrangement.

Mr. ORTON championed the cause of electrically-operated switchboards, and pointed out that mechanical operation had its limitations as to capacity. The paper was somewhat unfair towards electrical working, as in the list of apparatus required for this the whole of the arrangements used for the various types on the market were lumped together seemingly as one combination. He preferred the switchboard attendant to see what was going on, and not to be isolated in a separate switchboard room.

Dr. GARRARD did not consider that the right principles were applied in the cut-out recommended.

Mr. S. L. PEARCE thought that finality in reverse-current circuit breakers had not yet been reached. He preferred to couple generators direct to 'bus bars, and quoted instances of this having been done on failing generator when nothing untoward had happened.

Mr. E. W. COWAN pointed out that reverse-current circuit breakers had certainly saved machinery. He confirmed Mr. Woodbridge's mention as to the partiality of switchboard attendants for pulling out the wrong switch in an emergency.

Mr. TOPLIS preferred the three phases mechanically separated on the board to prevent a total breakdown. He concurred that the switchboard man should be in a position to see all the operations.

Mr. E. THOMAS believed that nothing at present was perfectly suitable, although good enough for most conditions to be met with. The switchboard man was the most usual reverse-current circuit breaker, but he had a very large time limit.

Mr. A. E. MCKENZIE thought that reverse-current circuit breakers would put stations in a hole sometimes, where, for instance, a generator motored owing to a Corliss valve sticking.

Mr. ANDREWS, in his reply, said that, when synchronising, the reverse-current circuit breaker should either be cut out or altered in sensitivity. He likened those engineers who would not use such cut-outs, on account of them not being able to do everything, to the man who would not use an umbrella because it did not keep the ends of his trousers dry. He compared Mr. Clothier's present admiration for bulky switchboards to Mr. Clothier's paper on the subject, which advocated compact designs. He admitted that 5,000 kw. was about the limit of a mechanical switch. He replied to Mr. Garrard's insinuations as to his lack of knowledge of the subject with the *tu quoque* argument.

A vote of thanks terminated an unusually late meeting.

ON BATTERIES WITH REVERSIBLE BOOSTERS.*

BY C. TURNBULL.

Introduction.—Some time ago I found it necessary to go into the question of having a battery and automatic reversible booster for use on the traction load at Tynemouth. The result of the investigation was the birth of the Lancashire Automatic Reversible Booster, which was brought out under the patents of Mr. McLeod and myself. This is now in considerable use, being made by the Lancashire Dynamo and Motor Company, of Manchester. In putting the machine into the various stations a number of points have come up in connection with the batteries, and to-night I wish to deal with them, in hopes that the paper may be of use to such engineers as are putting down batteries for use under similar conditions.

Price for Traction Current.—The method by which the price for traction current is fixed is one of mystery. Sometimes I think that the lowness of the rate obtained for this

* Paper read before the Newcastle Section of the Institution of Electrical Engineers.

Digitized by Google

kind of supply is partly to be accounted for by the fact that we sell in small units. Certainly the reduction from 2d. to 1d. per unit looks a good deal less than the reduction of a year's revenue from, say, £4,000 to £2,000. At any rate, however the price is fixed, it commonly happens that, when a station engineer takes over the management of a station, he finds the glorious tramway load, from which so much is expected, resolves itself into a small output at a remarkably small price, and the problem of making it pay occupies his thoughts for many years to come. I make these remarks here, as in addition to the Greenock case, other instances are coming to light in which the trams are claiming to be supplied at the same rates, or lower, as are in force for ordinary motor load, although it is common knowledge that tram load is of an entirely different description from motor load, and should be dealt with on its own basis. The practice of debiting all stand-by plant which can be used for both lighting and traction, to lighting only, is also not to be commended.

Load Factor.—The large published load factors for traction supply in combined lighting and traction stations are frequently made use of when a low rate for traction is asked. Certainly a 40 per cent. load factor (for I think that a figure as high as this has been given) looks a lot better than the 10 per cent. for lighting. Actually these large load factors are explained by the fact that the traction load is taken as that load which is on at the moment when the highest total combined load is on the station. Seeing that the highest combined load is usually on the station in the winter months, at a time when the traction load is often lower than its normal maximum, this system frequently causes the traction to be credited with a load factor much greater than it actually earns. To take an extreme case, in a station just beginning the highest combined load might be in the summer holidays, when the trams was heavy and the lighting very low. This would give a low traction load factor and a lighting load factor of perhaps 1,000 per cent.! In a few years' time, when the station had grown, the lighting load factor might have shrunk to ordinary dimensions, while the traction load factor might come out very high. I think there is a good deal to be said for taking the respective highest loads for calculating the respective load factors. In connection with this we must also remember that while an engine may be run at nearly full load all the time on motor load, on traction load one must always provide a very large reserve of power to meet the grossly fluctuating demands which traction involves, and this does not make for economy in generating the power.

Batteries.—It has now come to be recognised that the best way to deal with a very fluctuating traction load is to put in a battery and reversible booster, and to-night I propose to deal with some of the aspects of this solution of the problem. The idea has gained currency that a booster should be designed to keep the load on the generator always at a steady value. The problem is stated thus, omitting losses in battery and booster for simplicity: The output is 2,000 units per day of 20 hours. Then 100-kw. generator with a battery and booster will just do the trick. If the maximum load be 200 kw., then the battery should be able to give 100 kw. easily for a short time, so as to meet the peak with the aid of the generator.

In some cases where the output is fairly regular from day to day, and where the maximum demand keeps within limits, this solution of the problem is quite good, and a very efficient and good working plant is obtained by adding a battery and booster to the generator. In many cases, however, this solution is of no use at all. The output varies from day to day. Likewise a large part of the day is slack, with a heavy output during certain hours only. If in addition to this we have heavy and irregular peaks at all times, then it is evident we must solve the problem in quite a different manner. Take, for instance, a case where there is already installed a plant of 200 kw.; the output varies from 1,500 to 2,500 units per day of 20 hours, and the maximum demand is 400 kw. Then if we put a battery in with an output of 200 kw. for a short time, its maximum power added to the generator's maximum will give the required maximum demanded for the feeders. But if we attempt to run the generator at constant full load all the time, it will give off 4,000 units per day, and this will provide a large surplus at all times for boiling up the battery. The difficulty can be met by putting the machine to do only half load, but in this case the combination does not give out the 400 kw. needed to meet the heavy peaks which come on at intervals. Taking everything into consideration, then, it will be found that constant load on the generators can only be got in cases where the load is similar every day, and keeps on fairly regularly throughout the day, and where the size of the generator can be fixed so as to put out the proper amount of current every day at about full load. Of course, in many cases, a good deal can be done by varying the number of hours that the generator is run, so as to provide just the number of units required to meet the load and to keep the battery properly charged.

Properties of Booster.—For a general solution of the problem the booster should have very flexible properties. It should, indeed, fulfil the following requirements:

1. When required, it should work so as to keep the load on the generator approximately steady. This will be needed when the demand for current is approximately equal to the output of the generator. In this case, however, when a very heavy demand is made on the feeders, both generator and battery current should rise to meet it, so that the utmost power of the combination will be available. If this be not arranged, it will often be found that a heavy load will blow first one circuit breaker and then the other, although the combined maximum power of the battery and generator would have sufficient to meet the demand had the booster been arranged to allow the generator output to increase along with the battery's output.

2. It should be possible to vary the apportionment of the load between the battery and generator. In a slack time the battery should do very little. Also, if the traction peak should correspond with the lighting peak, then it may be desirable to let the battery take an extra load to relieve the boilers for the time being.

3. On a slack day with occasional peaks, the battery and booster combination should be arranged to respond to the peaks only, and otherwise do practically nothing, so as not to overcharge the battery. Sometimes the booster may be cut out altogether, and the battery may then with advantage be used to float on the line to meet any occasional rush of current.

4. For periods of very light load, the booster and battery should be arranged to go on to the 'bus bars without any generator. In this case the booster should be arranged to compound up to counteract the drop of volts in the battery.

I might point out that a booster worked by the feeder currents only will not fulfil these requirements, as such a combination will tend to take the load off the generator when the battery is fully charged, while it will be sluggish and unresponsive when the battery is down at all in volts.

Size of Cells.—Given a booster with the above properties, it is not difficult to arrive at the size of the cells. Thus with an output of about 3,000 units per day of 16 hours we can do it with a generator which will do 200 kw. as ordinary full load, with, say, a 25 per cent. overload capacity to meet excessive and occasional rushes. As we can now get economical triple-expansion engines or turbines which will run economically for long hours at full load and that will give off overloads either by means of valve gear or by working as compound engines, this part of the problem is easily solved. We must then put in a battery which will be large enough to meet the maximum load of the station when running in combination with the generator. Where the hours of actual load are longer or shorter than the 16 hours mentioned above, or where there is little or no load during part of them, then the problem can be solved in a similar manner. Given, however, a booster which will work in harmony with its generator as above, the solution will not be difficult, and a good deal can be done by varying the hours of running of the generator to suit. In buying cells under maintenance, it should be arranged that the circuit breaker should be set as high as possible. This is really unobjectionable, seeing that heavy

Digitized by Google

discharges are only momentary, and, further, the battery usually is not run down at all in working.

Type of Cells.—The actual work done by the cells when working with a reversible booster is very little. For although the curve of charge and discharge looks large enough in importance when it is examined on the recording ammeter chart, still the peaks integrate to very little. We, therefore, want a cell which will do with very heavy discharges, and also with considerable charges, but that does not necessarily have a large long hour capacity. Durability is more important than efficiency. As a matter of fact it is well known that a cell which receives charges and discharges at short intervals has an extraordinarily high efficiency, and a slight reduction in this if it gave increased durability, would not matter. I have been informed by one of our leading accumulator firms that a cell to meet those requirements can be made and maintained at about half the ordinary price if it be asked for, and I hope that such will be on the market in the near future.

Space for Additions.—It is a great advantage to have the cell boxes large enough to allow of the addition of more plates. This enables the size of the battery to be kept down, as it is easy to increase its capacity. If, however, more plates are added, then it is not desirable to simply put the new plates in parallel with the old ones. Old plates should be taken from some of the cells to make up the additional number required in the other cells, and the cells thus depleted should be made up entirely with new plates. The space at the side is useful in assisting the much-desired circulation of the acid. It also enables the cells to be inspected by an inspection lamp on an L-shaped stick. This lamp put under the plates shines upwards and shows any shorts clearly.

Space at Bottom.—The space at the bottom of the cells should be ample, about 6in. or so, so as to obviate frequent cleaning.

Number of Cells.—The possible variation of cell voltage is from 1·8 to 2·7 volts per cell, the last figure being obtained with the fortnightly overcharge, which makers recommend to be given to the cells. In ordinary working the variation is from 1·9 to 2·5 volts. Provided that the booster is arranged to prevent the current from coming back on to the generator, the number of cells may be varied considerably. I think, however, that 250 cells is a suitable number where the 'bus-bar pressure is between 500 and 550 volts. If fewer cells be used, a good deal of work is thrown upon the booster to pump the current out of them, and if more cells are installed there is a danger of the current coming back on to the generator if they be floated on the line without the booster when fully charged.

Instructions for Running the Battery.—This is a matter of great importance, and, unfortunately, battery makers usually give little assistance. It will be seen that it is necessary in working to ensure that the battery has just the right proportion of current put into it. Meters are of some assistance towards this end, but they must not be relied upon too much. It is doubtful if meters are quite accurate on the violently changing loads of a traction battery. Furthermore, it is likely that the effect of a discharge on the battery varies with the rate and also with the state of discharge that the battery is in. One hundred ampere-hours taken out of a battery just freshly charged will not need the same extra percentage to be put back that the same amount would need from a battery well run out—at least, I think not; indeed, as long as the load is of such a kind that the battery gets a charge immediately after a discharge—as happens when working with a reversible booster—then the excess percentage of charge over discharge in ampere-hours need be very little.

The advice is sometimes given that the booster should be worked so that the battery is charged every night at shutting-down time. This is impracticable without an undue amount of attention. The most practicable way that I have found is as follows: During the morning, when the generator is started up, there is usually a slack time, so that it can be arranged that the battery is mainly charging. The battery attendant should be in the battery-room now, and he should go round and see that every cell gasses up at the same time. He should watch the battery when it is gassing, and, at the same time, top up any cells with water if necessary. The water can be put in by a long glass tube, about 1½in. in diameter, with a bell mouth. This will enable the water to be put in at the bottom, and it can be stirred about and well mixed with the acid. The amount of gassing and volts per cell necessary on the daily charge should be determined by the battery makers, whose assistance should be freely requisitioned at first start up. When the cells are full up, the attendant should inform the engine-room staff, so that the booster can be regulated, so that the battery can be discharged for a time rather than charged. When a little current has been run off, the adjustment can be made so that charge and discharge are about equal or as needed. This method of working the battery needs a minimum of attention, and will be found very satisfactory in practice. Once a fortnight—if required by the makers—an extra charge can be put in, which will bring the voltage up to 2·6 or 2·7 per cell. This should be done at a quiet time, when the charge can be put in fairly steadily. The volts of each cell can then be taken on the top of the charge. The gravities of the cells can also be taken at the same time. The gravities can be relied upon to some extent to tell if the cells are getting their proper charge, but still these are affected by the addition of water to make up for evaporation. If a maintenance scheme is entered into, it should be on condition that the battery is to be worked on lines like this, and not on lighting battery lines.

Maintenance.—The question of the maintenance of batteries by makers is a thorny one. If the makers are good substantial and decent people, then there is some assurance to the owner of the battery in having a maintenance. Otherwise, it may happen that after several years of maintenance have been paid, that when repairs are needed the makers get out of their agreement by one of those curious clauses with which they fill their agreements. I mean, for instance, such a clause as that which states that the payments are to be made to the company *without demand!* It is possible to reduce the amount of the maintenance payment by stipulating for the battery to be kept up to, say, 90 per cent. of its original capacity instead of to the full capacity, and this is usually quite enough for reversible booster work. Indeed, with this proviso, the upkeep rate for a battery should be extremely low. The maintenance agreement should be settled as to terms before the order for the cells is definitely placed, as this will enable a better bargain to be struck. The user of the cells should then stipulate for six months' use of the cells before deciding whether to enter into the maintenance scheme or not. It is also desirable that the agreement should last over a long term of years—say 10—but with the user's option of terminating, say, after five years.

Water.—The question of water should be settled before the contract is placed. The makers usually stipulate for pure water only to be added to the cells, but if the town water is good, this is allowed. If this is not good, then the user is in a quandary as to how to make up the evaporation. Condensed water from a boiler is not always suitable, as it may contain boiler compounds, if such be used, or iron. Makers do not always help in the matter. Thus I know of one case where the engineer asked them to provide a distiller to provide make-up water, and they offered one, after several weeks of correspondence, for about £400! Rain-water is often too impure. I think that a simple distiller could, however, be made by using a gas jet under a boiler. The steam would go through a worm, and would be cooled by water in a tank. After the worm had gone through this tank it would go through a second tank. The boiler and the two tanks would be connected by a pipe so that the water would stand in the same level in all. This would cause the boiler to be automatically fed with hot water. A tap could run into the last tank to keep up the level, and also to provide cooling water.

Battery-Room.—It is often stated that battery-rooms should be well lighted. Actually too much light in a battery-room is bad, as it renders cell inspection difficult. The room should be rather dark, with good artificial lighting. The wiring may be done on insulators. At intervals lamps should be provided on long flexes of Lyric $^{3}/_{25}$ R.C. wire for looking into the cells from above. Hooks should be provided to hang these lamps on when not in use. I

Digitized by Google

have found acid-resisting paint liable to chip off a concrete ceiling, but wood varnished with acid-resisting varnish has stood better. The ventilation should be good, but of a nature to prevent flies and dust from coming in too freely.

Milking Booster.—This should be run off the lighting circuit so as not to be shut off if the main circuit breaker of the traction generator is blown. It is a debatable point as to how the leads should be run for milking up the cells. In the diagram, I show them run under the grating on the floor, being supported on insulators. The flexible leads can be connected by means of screwed plug handles. A small switchboard can be fixed in one end of the room, or possibly in a small room provided for the purpose. Where the cells are on two floors the switchboard should be provided with one pair of switch fuses only, to connect either the upstairs leads or the downstairs leads on to the 'bus bars. The use of a single pair of switch fuses prevents any attempt to milk up two parts of the battery at once, as, of course, only one pair of flexible leads is kept in a room. The booster can be put in a convenient place, but the regulation of its volts can be done from the battery-room. The booster may also be arranged to provide heavy currents for meter-testing purposes. The board should have a polarised ammeter and a voltmeter with paralleling and other stops on the switchboard.

Grating.—The grating for the battery-room floor can be made of rough wood dipped into melted pitch. This makes quite a cheap and satisfactory arrangement.

Reversible Booster Switchboard.—The breakers, of the booster-motor and battery, should be on the live side, but most of the rest of the instruments on the board may be

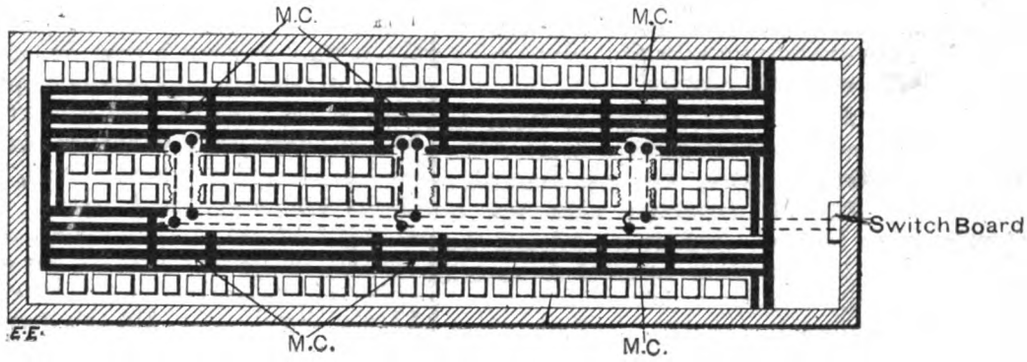

Diagram showing Arrangement of Trolley Wire Conductors for Milking-up Cells. The Grating is showing Broken Away to show the Trolley Wire which is underneath. M.C. indicates Moveable Coves by which plugs are got at.

on the earth side. The motor breaker should be arranged to shut off the battery current, if it comes out, so that the booster may not race owing to the battery current running through it. On the other hand, it is desirable to have the breakers arranged so that the blowing of the battery breaker does not stop the motor.

Meters.—Wattmeters may be used with the shunts taken off the 'bus bar, so that they virtually become ampere-hour meters. I have tried oscillating meters, which have the advantage that they do not need any pawls to stop them from running reversely. I think that mercury electrolytics or some shunted ampere-hour meters with a small drop might be used. One shunt would do for both. In this case the auto switch for putting either one or the other in circuit, according as the battery was charging or discharging, would be simply a mid-zero ammeter type of instrument, only that the pointer would have a contact on the end. This contact would swing up against one or the other of fixed contacts, and so direct the current into the right meter.

Testing of Meters.—It is not essential that the integrating meters should be absolutely correct, but it is essential that they should agree with each other, or that their differences should be known. They can easily be tested for this by simply reversing the connections of one so that they both read for charge, or discharge, for a day or two. The readings thus got will show whether the meters are agreeing.

Shunts.—The abomination of several shunts in series—one for the ammeter, one for the recorder, and one for the integrators—should be avoided. One shunt should do for the lot, or if two in series be used, then the instrument having the heaviest drop should come off the combined resistance of the two shunts. In this latter case the two shunts in series should be soldered together, so that the combined resistance could not be affected by bad contact.

Arrangement of Plant.—In some stations I think it would be a good thing to couple the booster right on to the main generator shaft, so as to save motor losses. In many cases I think it would be well to run traction and lighting dynamos in tandem on the same engine. Where a reversible booster was in use, the load on the traction generator would be steady enough to prevent flickering on the lighting boards due to variations in the engine speed. Two ideas are possible: Either the generator can be looked on as a traction generator, in which case the traction dynamo would be equal in capacity to the engine, and the lighting dynamo would be equal to the day load on the lighting board; or the lighting dynamo can be of the engine capacity and the traction one smaller. At night or on the peak loads, of course, when desired the loads could be separated out. The lighting dynamo could have the mid-wire connection through choking coils, which would obviate the running of a balancer in the daytime. Given, say, some 200 kw. on the traction and, say, 100 kw. on the lighting all day long, then the combination would provide quite a good load for a 400-kw. or 500-kw. engine. If the condensing plant were run direct off the engine shafting by chain or other gearing, we would have a very economical omnibus plant for many stations. Of course, one may say that there would be a lot of eggs in one basket in case of breakdown, but then plant does not break down now as it used to, and, of course, the ordinary stand-by plant would be necessary as it is now. The amount of current that runs to waste nowadays in running balancers and motors for various purposes is so enormous that it is worth while to do something to save it.

Conclusion.—I have written this paper at somewhat short notice, although, of course, the subject has been in my mind for a long time. Had I had more time it would have been possible to provide some diagrams, but I hope that the absence of them will not be unduly felt. Indeed, the style of the diagrams necessary to illustrate a paper of this kind is so well known that it is doubtful if they are necessary. I can only hope that the contents of the paper will be useful and interesting to all concerned in matters of this kind.

FORTHCOMING EVENTS.

Jan. 5.—A general meeting of the Röntgen Society will be held at 8.15 p.m., when Mr. C. E. S. Phillips will give a description of an automatic vacuum pump, which will be followed by an exhibition of a method by which strongly-adherent films of aluminium may be applied to glass; and "A Note on the Colouration of Glass by Radium Radiation."

Jan. 10 and 11.—At the Institution of Civil Engineers, Sir W. H. White will deliver an address, entitled "The Recent Visit to the United States and Canada."

Jan. 13.—A lecture, entitled "Theory of Electricity and Magnetism," will be delivered by Mr. J. Swinburne to the students of the Institution of Civil Engineers.

Jan. 27.—The following papers will be read at the Physical Society: "Action of a Magnetic Field on the Discharge through a Gas," by Dr. R. S. Willows; "Action of Radium on the Electric Spark," by Dr. Willows and Mr. J. Peck; "The Slow Stretch in India-rubber, Glass, and Metal Wires when subjected to a Constant Pull," by Mr. J. Phillips; "Determination of Young's Modulus for Glass," by Mr. C. A. Bell; and "Some Methods for Studying the Viscosity of Solids," by Dr. Boris Weinberg.

TO CORRESPONDENTS.

All Rights Reserved. *Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.*

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "The Electrical Engineer," containing half-year's copies, bound in Dark-Blue Cloth, Gold-Lettered, price 8s. 6d. New Volume, January to June, 1904, now ready.

THE METRIC FALLACY.

It was with some reluctance we entered into this controversy, it is with diffidence we continue it. While the late Sir F. Bramwell, with his experience and his influence, was alive to speak, the matter was in able hands. With his death it behoves all who have thought of the subject to band together to oppose the insidious but energetic campaign of the metric advocates, and by weight of numbers, even if the influence be really lacking, to show that the arguments of the advocates are not altogether convincing. The late I. Todhunter was once out of temper at the constant iteration of men who knew not what they were talking about, and who bewailed the dearth of mathematicians in Britain, extolling to the skies the number and ability of foreign mathematicians. He said, "Look here; write down your foreign names, and I will write against each the name of a Briton who shall equal him in knowledge and ability. Make your list as long as you like." Perhaps, then, we are modest, and in losing Sir F. Bramwell may not have lost all ability or influence, but if put to the test might find firms and individuals who oppose; as able as well known, and as experienced as any who support the metric fallacy. In reply to Lord Belhaven, we can at present touch briefly only on certain points. Thus the reports of consuls need far more discussion that can now be given, but after twenty-five years of examination of them we are not surprised at anything they contain, and always want to know a good deal more than the reports give. A first and very pertinent question is, Who and what is the consul? Non-limitation to foreign trade, because "every trade calculation will be reduced to one-third of its present length." Now, how does the metric system deal with time? Surely time is a function in most trade calculations. Then navigators cannot or won't use the metric system—if any do, where are they to be found? "The French people have refused to have the 10-hour day . . . and the French navigator threw overboard his 10-hour day, his 400deg. circle, and his kilometre" (British Weights and Measures Association's pamphlet, p. 2). "We are not aware of any single country in the world, not even France, that has made the metric system its textile standard" (same pamphlet, p. 3). Two yards (shipbuilding) "one of considerable importance at Flensburg, and one at Hamburg, still use the English system of measurement for their shipwork" (Halsey and Dale, p. 41). "The millimetre has not yet driven the inch from German machine shops, and that Germany is still in the transition period" (p. 41). "*Every* trade calculation reduced, etc." Halsey's book rather controverts this idea, as, if we recollect rightly, did the late Sir F. Bramwell, and as does everybody who can use figures. Sometimes a reduction will take place by using one method, sometimes by using another, but to claim universality of reduction for any one method is an absurdity. On p. 146 of Halsey are certain calculations, and he says, "the introduction of the metric system into that school has made it possible with 245 figures to arrive at the same result that is reached with 223 figures by the elementary English formulas or with 160 figures by (English) mill methods.' On p. 205 are other examples giving results: English 15 figures, metric 27 figures; English 15, metric 23; English 16, metric 25; English 38, metric 22. The metric system does not show up very well as a reducing system for calculation. The English textile standards are six in number, the metric eight (p. 197). A French textile manufacturer says: "We are as much in the anarchy of weights and measures for the textile industry as at the time of

Digitized by Google

the Revolution." This does not seem to prove simplicity, or even a desire in metric countries to adopt a metric system. Comment is made as to our reference to professors and students, and it is pointed out that certain eminent firms support metric reform. We agree that that is so, but to attempt to analyse the reasons why certain firms support the system would entail too much space—they are perfectly obvious in many cases. However, when a list of firms in the textile industries—that is, when Lancashire, Yorkshire, Gloucestershire, Wilts, etc.—show a leaning that way, will be time enough to claim practical men in support. The metric system in France. Casually we have referred to the textile industry—the British Weights and Measures Association calls attention also to the hat trade (p. 3), and Halsey (pp. 60-69) gives over five hundred non-metric units used in metric countries, many of these in France and French-speaking places. Is it not absurd to give a list of English variants, and claim them as showing the badness of the system, and refer to French variants as showing nothing. Halsey (pp. 28-38) deals with the persistence of old units in France, and in his introduction says: "Nowhere has the system made material progress in industry except when backed by the policeman's club. For more than a century it has been the pet of the legislator, and with the result that in France to-day its most ardent advocates are calling for more laws to compel its use by whole industries that do not, and by the testimony of these same advocates will not, use it unless compelled to do so." We have already exceeded our space, or we should have referred to the advocacy of Mr. T. Parker that the inch should be retained, but we would just like to point out that the English system of weights and measures, although possessing features which might well be modified, possess some advantages also. Take the case of the gallon: in one of Prof. Henry Robinson's books he gives a chapter on memoranda; the first is, "a gallon of water weighs 10lb." Here, then, is a decimal system, more or less, and we agree that many of the calculations involving these quantities are exceedingly simple. We are not, and never have been, against the use of decimals. We use decimals when they assist; we use vulgar fractions also when they assist.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE ELECTRICAL TRADES' BENEVOLENT FUND.

SIR,—Whilst fully sympathising with the efforts of Mr. Justus Eck and his friends to promote a benevolent fund for the benefit of necessitous members of the electrical industry, may I be permitted to point out that there is already in existence a benevolent fund in connection with the Institution of Electrical Engineers for the purpose of assisting members, or the families of members, in temporary or permanent need.

Efforts are now being made to improve the position of this fund, and I shall be pleased to forward the rules to any member who may desire to have a copy.—Yours, etc.,

G. C. LLOYD,
Hon. Sec. to the Benevolent Fund of the I.E.E.

[We are sure that the treasurer will be equally pleased to send receipts for a large number of contributions to the fund.—ED., *E. E.*]

SIR,—I am obliged to you for the criticism you gave in your last issue on my letter on the above subject.

The Electrical Trades' Benevolent Institution Fund is intended to benefit all deserving persons engaged in the electrical industry who may fall in need, and is, therefore, in no sense in opposition to the benevolent fund of the Institution of Electrical Engineers, which is for the benefit only of members of that institution.

The source of revenue of the Institution of Electrical Engineers' fund is its own members; that of the electrical trades' fund will be very much larger, and should include all persons who benefit directly or indirectly from the practical applications of electricity.

Again, any funds belonging to a trade union are circumscribed both in the collecting and distributing areas. The electrical industry, now many years old, employs many thousands of individuals who cannot be assisted by either of the funds you mention. There is, therefore, ample scope for the new fund, which, supported as it is by the employers of many hundreds of hands, and pioneered by an active and industrious committee, will soon make an appeal upon lines that should command a very good reception from all classes.—Yours, etc., JUSTUS ECK.

10, Priory-road, Bedford Park, W., Dec. 18, 1904.

[We are pleased to publish further details of the above scheme, which is very wide-reaching. The principle of mutual assistance has our hearty approval, and we trust that the committee will be able to solve the many difficulties in the work before them. We are afraid that the equitable distribution of funds amongst the many grades interested will be a more difficult matter than the collection of the same. This was what led us to refer to the benevolent fund of the Institution, and to the trade and friendly societies, in our last issue as having benevolent schemes already in operation. Many of our large firms also have such funds, subscribed to regularly by the workmen and staff.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

SIR,—I beg to draw your attention to a mistake in the answer to question 737, appearing in the "Supplement," Dec. 16.

The rule is given in the latter portion of the answer, when locating a fault by Murray's loop test, "the fault on the loop, A B, being nearest to that end of the bridge which gives the greatest length between its end and the test contact."

This should read, "the fault on the loop being nearer to that end of the bridge which gives the *shorter* length between its end and the test contact."

This error is in evidence both in the diagram and calculation.—Yours, etc., R. A. O'NEILL.

THE METRIC FALLACY.

SIR,—In your issue of Dec. 2 you publish an article on the "Metric Fallacy." May I be permitted to reply to some of the points contained in it?

You refer to a volume by an American author discussing this same fallacy. Is it generally known that America has so far departed from the British system of weights and measures as to adopt the metre as the fundamental standard of length, the yard being derived from such standard metre? Is this a part of the metric fallacy? You say, "the aim of the practical man is simplification of work and getting of business." That is precisely our point. That is why British consuls all over the world have for years been urging the adoption of the metric system in the interests of British trade.

When I speak of trade I do not limit the benefits of the metric system to *foreign* trade. It is quite as much, if not more, to the advantage of our home trade that the cumbrous system of weights and measures from which we suffer should be replaced by one in which every trade calculation will be reduced to one-third of its present length.

You speak of the agitation in favour of the adoption of the metric system in this country as the agitation of a few professors and students—that is, I think, a fair interpretation to be placed upon words used in your article. The accompanying list of eminent commercial and manufacturing firms who support the reform in question is probably too long for insertion here, but would amply convince your readers that if the practical men in this country are all on one side, they are certainly not on the side of our own perplexing weights and measures.

Digitized by Google

Let me pass to your argument that the metric system is not fully adopted in France. In reply to questions put by the American Chamber of Commerce of Paris in October, 1903, on this point, the Société des Ingénieurs Civils de France stated as follows: "To-day only one system of measures exists in France, and it is absolutely incorrect to say that the old measures are still employed in this country; even their values are becoming more unknown. The popular names of the old measures, which, as stated before, designate, at the present time, metric measures, have given rise to the belief that the two systems are co-existent."

It is as absurd to say that the metric system is not wholly adopted in France to-day as it would be to maintain that English is not the universal language in this country because in outlying districts of Wales, or the Highlands, it is not always used.

Moreover, if the custom house in a metric-using country requires all invoices to be made out in the metric system, it matters very little for purposes of our export trade what weights and measures prevail in the far interior of that country.

It is obvious that if the proposal of the British Weights and Measures Association to standardise and simplify British weights and measures be carried out, the confusion and expense of change to their new simplified system would be as great as the change to the metric system, and we should be left out of harmony with metric countries, and even out of harmony with the United States—a position of "splendid isolation."

It is a common thing to hear on the part of those opposed to the adoption of the metric system that it would be a simple matter to adopt a decimal system of weights and measures based on our present measures of an inch or a pound weight. But none of those who say this have ever published a scheme, for the best of reasons that such a system would (1) be as difficult to introduce as the metric; (2) lose the advantage of the inter-correspondence possessed by the metric system in the relations of length, weights, and capacity; (3) lose the benefit of uniformity with other nations, which is one of the most important objects to be obtained by making a change. The accompanying list of customary, but illegal, weights and measures used in this country will show that the work of simplifying and standardising will be a serious matter, and should convince your readers that it will be better to make a clean sweep of them, rather than attempting a patching-up process.

As an example of the feeling in the United States, the following quotation from the report of the Secretary of the Treasury at Washington issued in June last year may be instructive: "During the year the attention of this department has been forcibly called to the growing need for international uniformity in so fundamental a necessity to trade as weights and measures. The customs congress of American republics, held at New York, strongly urged the adoption of the metric system to simplify the transaction of Government business in connection with international trade. Moreover, the National Board of Trade of the United States, the Board of Trade of Canada, and the congress of chambers of commerce of the British Empire have recently urged by strong resolutions the adoption of the metric system. The experience of 40 countries of the world has proved beyond question that the international metric system is unsurpassed for practical convenience, possessing, as it does, a terminology concise, definite, and free from ambiguity, affording a maximum facility in the countless transactions and computations of science, manufacture, and commerce."

Finally, you say that it is a question "of the Latin races against the Anglo-Saxon—once more lightness, alertness, flexibility, as against solidity and phlegmatism." May I ask under which of these heads you place the Germans?—

Yours, etc.,
BELHAVEN AND STENTON,
Vice-President of the Decimal Association.

List of Anomalous Customary Measures and Weights submitted to the Select Committee of 1895 by the Chairman of the Society of Inspectors of Weights and Measures.

A pot of apples, in Wolverhampton, equals 75lb.
A pot of beans and peas, in Warwickshire, equals 40lb.
A tub of potatoes, in York city, equals 20 stone—*i.e.*, 2½ cwt.
A pound of butter, in Wigan, equals 16oz. or 17oz.
A sieve of vegetables, in West Ham, equals 1 bushel.
A sieve of vegetables, in Rochester, varies 7, 8, and 9 gallons to the bushel.
A sieve of vegetables, in York city, varies 24lb. to 42lb.
A sieve of plums or black currants, in Warrington, varies 10lb. to 50lb.
A bushel of peas, in Wigan, equals 60lb.
A bushel of potatoes, in Wigan, equals 84lb.
A bushel of corn, in Hereford, equals 63lb.
A bushel of corn, in Newtown, equals 80lb.
(But the greatest absurdity is to be found in Cornwall, where it is actually supposed to contain 240lb.)
A "stone" of live meat equals 14lb.
A "stone" of dead meat equals 8lb.
A "stone" of cheese equals 16lb.
A "hobbet" of old potatoes, in Flintshire, equals 200lb.
A "hobbet" of new potatoes, in Flintshire, equals 210lb.
A "Llestr" of lime, in Carnarvonshire, equals 1 bushel.
A "punnet" of strawberries, in Greenock, varies from ¾lb. to 1lb.
(In Forfar fruit is sold by the Scotch pint, and by the "choppin." A Scotch pint equals three Imperial pints, and the "choppin" equals 1½ pints).
In Dumfriesshire the Scotch pint equals four imperial pints.
Vegetables are sold in Flintshire, in "lippins," a lippin equals ½ gallon.
A "molley" for vegetables, in Northamptonshire, varies from 12lb. to 40lb., there being large and small mollies.
A "molley" for vegetables, in Chester, equals 3½ gallons.
A peck of fruit, in Manchester, varies from 14lb. to 18lb.
A pad of potatoes, in Middlesex, equals 112lb.
A punnet of vegetables, in Middlesex, equals 1lb.
A nipper of vegetables, in Middlesex, equals 12lb.
A pack of vegetables, in Huddersfield, equals 240lb.
A hoop of vegetables, in Kendal, equals 1 Imperial gallon.
A peck of potatoes, Gloucester, equals 14lb.
A peck of potatoes, heaped, in Gloucester, equals 16lb.
A seam of straw, in Devon, equals 200lb.
A seam of hay, in Devon, equals 373lb.
A seam of dry wood, in Devon, equals 280lb.
In Northumberland they sell vegetables by the "forpet," which equals 1 gallon; by the half-forpet, which equals ½ gallon; and by the "beatment" which also equals a gallon.
A pottle of vegetables, in Buckinghamshire, equals ½ Imperial gallon.
A flat of vegetables, in Buckinghamshire, equals 1 bushel.
In Cambridge borough butter is sold by the yard; each yard is supposed to weigh a pound.
A boll of wheat, in Buteshire, equals 240lb.
A boll of barley, in Buteshire, equals 320lb.
A boll of oats, in Argyllshire, equals 6 bushels.
A bushel of corn, in Sunderland, equals 46lb.
A bushel of corn, in Shropshire, varies, 72lb. to 75lb.
A seam of green wood, in Devon, equals 336lb.
In South Wales, in place of liquor being sold in pints and half-pints, it is sold in an illegal measure called the "blue," or "sleever," which contains a third of a quart. An inspector recently informed me that in place of three measuring a quart—viz., 8 gills—that many only measure 7 gills, so their abolition would be a benefit to the poor man.

The following is a List of the different Measures used in the Sale of Wheat, which appeared in a letter from one interested in the Corn Trade in the Daily Mail of Jan 28 1904:

Quarter of 8 imp. bushels (496lb.) country districts.
Quarter of 8 imp. bushels (504lb.) at London.
Coomb of 4 bushels at Beccles.
Load of 3 bushels at Sheffield and Doncaster.
Load of 5 quarters at Oxford and Cirencester.
Load of 5 imp. bushels at Bedford.
Boll of 3 imp. bushels at Newcastle, Carlisle, etc.
Boll of 6 imp. bushels at Berwick, Duns, and Kelso.
Boll of 4 imp. bushels throughout Scotland.
Bushel of 62lb. at Birmingham, Gloucester, and Taunton.
Bushel of 70lb. at Liverpool and Manchester.
Bushel of 75lb. at Chester, Shrewsbury, and Nantwich.
Bushel of 80lb. at Monmouth and Abergavenny.
Bushel of 65lb. at Aberystwyth.
Boll of 264lb. at Glasgow.
Boll of 240lb. at Hamilton.
Barrel of 280lb. at Dublin and Cork.
Cwt. of 112lb. at Bedford and Newry.
Cental of 100lb. at Liverpool.
Windle of 220lb. at Preston.
Hobbet of 168lb. at Denbigh.

Units in Use in the Foreign Grain and Flour Trade.

14lb.	20lb.	45lb.	60lb.	100lb.	189lb.	196lb.	210lb.	224lb.
304lb.	312lb.	320 lb.	336lb.	400lb.	480lb.	448lb.	476lb.	492lb.
496lb.	500lb.	504lb.	520lb.	532lb.	2240lb.	32lb.	34lb.	112lb.
		56lb.		1000 kilos.		Quintal.		

The correspondent who supplied this list wrote on April 21, 1904, as follows: "It is openly stated by grain traders that they would object to a *uniform* system of weights, as they would thereby lose the pull which they can get with countrymen by buying on one weight and selling on another."

THE COMBINATION OF DUST DESTRUCTORS AND ELECTRICITY WORKS ECONOMICALLY CONSIDERED.

Mr. W. P. Adams read a paper on this subject on the 15th inst. before the Institution of Electrical Engineers.

Dealing first with the financial aspect of the matter, he emphasised the desirability of keeping the accounts of the two departments quite distinct.

Descriptions were given of all the combined stations in the country, and copious curves were presented illustrative of the conditions and progress at the various works. The author remarks that there is often a considerable difference between the value of winter and summer refuse in a given town, and also a variation in the quantity collected. It is worthy of note that these variations correspond very fairly with the fall and rise of the summer and winter output of electricity, the winter refuse generally being of the higher value.

Below is a table of the net units of electricity derived per ton of refuse burnt, taken over a year. The figure fluctuates in a large degree with the conditions. Mr. Adams mentioned the case of Hackney, which on Dec. 17 last year obtained a value of 105 8 units per ton on the peak load. This figure was obtained under ordinary working conditions, and, given a sufficiently large load (such as that obtained at Shoreditch), Mr. Adams sees no reason why 100 units per ton should not be reached throughout the day.

Name of town.		Units per ton of refuse burnt.
London —	Shoreditch	21
	,,	28·5
	Stepney	28·3
	Fulham	26·2
	Hackney	37
	Bermondsey	29·8
Provincial—	Shipley	30
	Beckenham	12·8
	Partick	29·6
	Nelson	40
	Mexborough	25·5
	Gloucester	15·3
	Grays	15·0
	,,	21·0
	St. Helens	31
	Accrington	10·6
	Bangor	15

Mr. Adams thus concludes his paper: The question of combined electricity works and dust destructors promises to assume very large proportions, and it is desirable to realise that it is only some five years since the pioneer works at Shoreditch were erected. Every town of over 10,000 inhabitants will probably in the course of a few years be provided with destructors, and if the heat value is sufficient to pay a large part of, and, perhaps, in some cases the whole, cost of destroying the refuse, the economy of combined works is a matter of high importance to ratepayers throughout the country. It is probable that many of the large existing destructors might be economically adapted for the generation of steam. Several instances have come under my notice, and I have recently been required to report in such a case. The conclusions come to are not a little interesting, and the economy of the proposed alteration for generating electricity is very considerable. It may not always happen that existing destructors are situated satisfactorily from an electrical point of view, but the transmission of the electricity generated to the electricity works or to a sub-station, is not a problem presenting any serious difficulty.

The surprising results obtained in the London undertakings which I have had the advantage of introducing to your notice this evening, may well give rise to some curiosity as to the values which will be ultimately secured in large combined works. After a study of the Fulham and Hackney curves, an average in the neighbourhood of 100 units per ton would appear to be within reach, and the heat value is certainly contained in the refuse, if only it can be fully utilised.

So long ago as 1902, Prof. George Forbes stated in a lecture before the Society of Arts that if the refuse then collected in Paddington were properly burnt and used in the most economical way, it should provide enough electricity to light one 8-c.p. lamp for two hours every night of the year per head of the population, which is the estimated amount of light demanded by the exigencies of modern civilisation. It is a great pleasure to me to take upon myself the vindication of Prof. Forbes as a prophet, for by the exercise of a small amount of scientific license I am able to demonstrate that in at least two metropolitan boroughs this result will certainly be achieved within a few years. A 30-watt carbon lamp burning two hours per night throughout the year would absorb 22 units. A Nernst lamp giving the same light would burn, say, 11 units. The population of Fulham is 150,000, thus 1,650,000 units would be required; the ultimate value is estimated at 1,870,000 units. The population of Hackney is 230,000, the units required would amount to 2,530,000 units; the ultimate value of the Hackney refuse as estimated by Mr. Robinson is 2,436,000.

I will ask you to bear with me while I make a modest little calculation on my own responsibility. The annual collection of refuse in London amounts to approximately 1¼ million tons. Taking so low an average as 40 units per ton as its potential capacity for generating electricity, no less a sum than £200,000 per annum—taking the average coal cost of all the London undertakings—is being tipped on dust heaps, resolved into vapour, and deliberately barged out to sea at heavy cost.

Conclusions—As I am addressing engineers, I need summarise my conclusions but briefly.

1. The remarkable figures obtained in some undertakings, as demonstrated in the series of curves I have had the privilege of laying before you, are evidence that great advances have been made in the problem of utilising waste heat from burning refuse in destructors since the pioneer works were started.

2. That these results still leave room for substantial improvement (*a*) by closer attention to the details of construction of furnaces and flues, and the general arrangement of the plant; (*b*) by improving the methods of handling and burning the refuse; (*c*) by careful utilisation of the steam generated, and the adoption of an economical form of blast.

3. That given suitable conditions, there is without doubt a substantial gain to be effected by the combination of electricity and destructor works; but owing to the variation in the calorific value of refuse in different localities, and to other special local considerations, every proposed case of combination needs to be considered on its merits by persons qualified to make an independent and intelligent enquiry.

Digitized by Google

4. That the various and in some cases crude methods in vogue of adjusting accounts between the two works need to be systematised, and that it is highly desirable that the results obtained be separated and recorded with accuracy, so as to give, so far as possible, a true record of the financial position of both works.

[The figures given in the paragraph immediately preceding the "Conclusions," are as amended by the author on the reading of the paper, and not as originally printed, the revised numbers embodying substantial increases.]

The following is a synopsis of the discussion:

Mr. Highfield, late of the St. Helens works, stated that the load factor at his station was extremely high, so the refuse had had a chance of giving the best results. Taken over a year, they had obtained 36 units per ton of refuse. He pointed out that the units yielded by the refuse started rather badly in the morning, which he attributed to the varying quality of the refuse throughout the day. As a rule he found that the last load of the day to come in was of very moderate value and decidedly odoriferous. The dust destructor was not a nice neighbour, and the only way to prevent dust, etc., leaking through and affecting the electrical machinery was to erect an enormous wall. He did not think it fair to take the coal consumption on light load and make that the basis for calculating the value of refuse burnt at peak time. He thought the calculations of the author, based on the prophecy of Dr. Geo. Forbes, referred to in the above abstract, were over-sanguine, as witness Montreal, where the figures were quite out of proportion to those mentioned above.

Mr. Newton Russell congratulated the author upon his paper, which must have involved a great amount of work. In regard to the statement that at Shoreditch "dampers are provided between the destructor and boiler furnaces to cut off the former when not in use," the great heat had caused the dampers to burn out in a very few weeks, and the construction of the cells would not allow of their being replaced, so that the operations had been carried out under disadvantageous circumstances. In reference to the author's tables, Mr. Russell pointed out that the value of the refuse does not altogether depend upon its calorific value, but has to be coupled with the efficiency of the electrical generating plant. For instance, at Fulham he understood that it required 50lb. to 60lb. of steam to generate one unit of electricity, while at Hackney (one of the most modern stations) it only required 27lb. to 31lb. Mr. Russell thought the author had scarcely given sufficient consideration to the extra land required when dust destructor works were added to the plant. This extra land in London districts represented a heavy figure. He quite approved of the author's views in regard to separate accounts for the two departments, though this was not quite practicable in the case of Shoreditch, because the steam was used for other purposes as well as for generating electricity. Mr. Russell stated that as the result of experiments he had conducted he was convinced that the maximum heat was not obtained from the refuse by the present practice, and that it could be burned down to a considerably lower point; in fact, he had found it melt itself and run out like slack in an iron furnace.

Mr. L. L. Robinson advocated very low prices for power, so as to encourage a large day load in preference to putting in a big battery. He concurred with the author in regard to separate accounts, of which a special point was made at Hackney. The lax method of keeping accounts greatly impaired the value of the author's comparative tables. The coal bill at Hackney was lower than at any other of the works dealt with, this being attributable to triple-expansion engines, superheat, condensers, automatic stokers, and electrically-driven auxiliaries. He dissented from the author's statement that a refuse destructor means a saving of labour to the electricity works. This had certainly not been the experience at Hackney. The author was too sanguine about the disposal of clinker, which was becoming a greater glut in the market than ever. He deprecated on hygienic grounds the author's suggestion that money should be made by letting people pick over the refuse. Considerable trouble arose in the electricity works from the dust creeping into the engine-house, etc. He was not much in favour of running the refuse to the last ounce; he would rather keep "a little in hand." The author had treated the Hackney works unfairly by giving the costs per ton destroyed an undue load of capital charges.

NEW YORK CENTRAL TRIALS.

For the purpose of experimenting with their electric locomotives, the New York Central Railroad Company and the General Electric Company are equipping a six-mile track from Schenectady to Hoffmans for testing purposes. Power is supplied from the generating station at Schenectady at 11,000 volts, which is transformed down to 460 volts at the Wyatts sub-station, five miles distant, the conditions corresponding as nearly as possible with those to be met in actual practice. As the track is not yet finished no complete tests have been made, but some preliminary runs have been carried out for the electric traction commission of the company. The two first diagrams give speed, current input, and voltage at the locomotive, all on a time basis, with an eight-car train weighing 336 tons and a four-car train weighing 170 tons, both exclusive of locomotive. The total weight of train, including locomotive and passengers, was 431 tons, and 265 tons for the eight-car and four-car trains respectively. Two sets of starting tests are illustrated (Fig. 3),

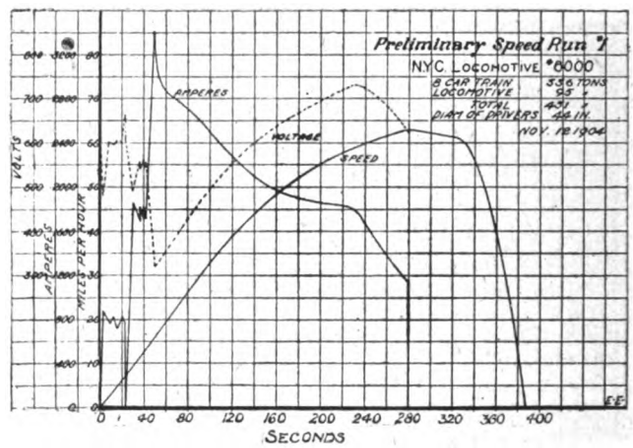

FIG 1.

showing the more rapid rate of acceleration possible with the higher maintained voltage available near the sub-station. The speeds reached were 63 miles per hour with an eight-car train and 72 miles per hour with a four-car train—the maxima obtainable on the length of track available. It

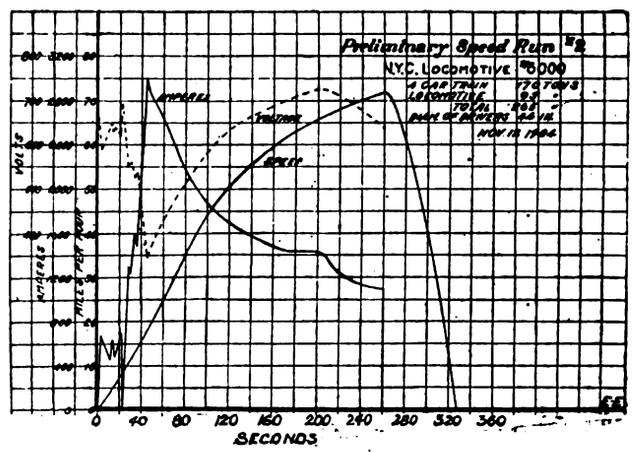

FIG. 2.

will be noted that the trains were still accelerating at these speeds, but the length of track so far equipped did not permit attaining higher speeds. The New York Central locomotives are not designed for abnormally high speeds at intervals, but rather to obtain a high average

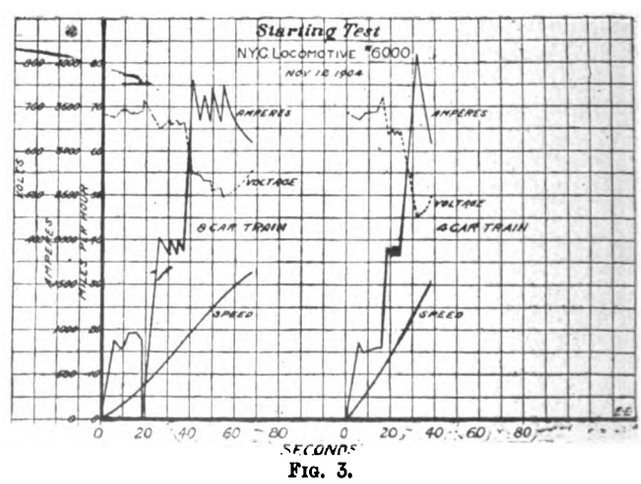

FIG. 3.

schedule, due to their ability to accelerate more rapidly than is possible with the present steam locomotives. In the starting tests a speed of 30 miles per hour was reached in 60 seconds with an eight-car train weighing, including the locomotive, 431 tons, corresponding to an

Digitized by Google

acceleration of one-half mile per hour per second. During certain periods of the acceleration the increase in speed amounted to 0·6 mile per hour per second, calling for a tractive effort of approximately 27,000lb. developed at the rim of the locomotive drivers. This value was somewhat exceeded with the four-car train, where a momentary input of 4,200 amperes developed a tractive effort of 31,000lb. at the drivers, with a coefficient of traction of 22 5 per cent. of weight on drivers. The average rate of acceleration with the four-car train, weighing, including the locomotive, 265 tons, was 30 miles in 37½ seconds, or 0·8 mile per hour per second, calling for an average tractive effort of 22,000lb. The maximum input recorded, 4,200 amperes at 460 volts, or 1,935 kw., gives an output of the motors of 2,200 h.p. available at the wheel. With 4,200 amperes and a maintained potential of 600 volts there would have been an input to the locomotive of 2,520 kw., corresponding to 2,870 h p. output of the motors. This output is secured without in any way exceeding the safe commutation limit of the motors and with a coefficient of traction of only 22·5 per cent. of the weight upon the drivers, thus placing this electric locomotive in advance of any steam locomotive yet built. No service capacity temperature runs have been made as yet, and the preliminary tests have not

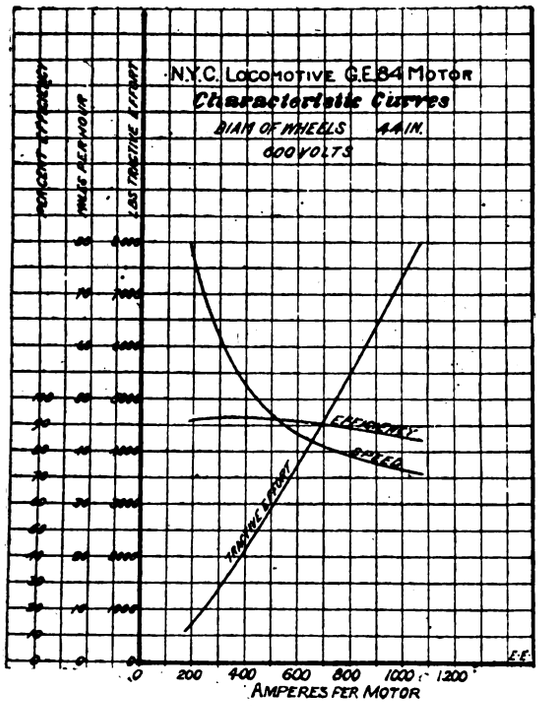

FIG. 4.

shown any appreciable warming up of the motors sufficiently to take thermometer readings. Throughout both the starting and running tests the electric locomotive shows its remarkable steadiness in running, a distinct contrast in this respect to the steam locomotive, especially should the latter be forced to perform the work here shown to be accomplished by the electric locomotive. The elimination of gear and bearing losses permits of a very high efficiency of the locomotive. Reference to the motor characteristics (Fig. 4) shows a maximum efficiency of approximately 93 per cent., this value being some 4 per cent. better than possible with motors of the geared type. This gain is especially noticeable at high speeds, the efficiency curve remaining above 90 per cent. even at the free running speed of the locomotive alone.

STEAM-PIPES.

BY F. H. DAVIES.

The steady increase in steam pressures that has taken place during the last few decades has naturally altered ideas and practice in steam-pipe work to a considerable extent, and has resulted, among other things, in investigations of the behaviour of steam under various conditions of restriction and flow, and in recognition of the importance of sundry details of pipework that formerly were deemed of small consequence.

The economic and other laws that govern the efficient conduction of steam are, of course, well known, being on the whole very similar to those that apply to fluids. Of these, one of the most important from the point of view of design is that relating to the maximum permissible velocity of flow of steam in pipes, which has been laid down by different authorities as varying from 6,000ft. to 8,000ft. per minute. Experience, however, shows that such hard-and-fast statements cannot be accepted as finite, and that, with all due regard to economy, under certain conditions these amounts may be safely exceeded, as under other conditions they must not be approached. The percentage of allowable drop, diameter of pipe, and pressure of steam all have a bearing upon this question; and as the two latter, at any rate, vary very considerably in steam installations, it is obvious that any attempt to specify a finite and all-round figure must be futile. The lower the pressure of steam, the greater is the permissible velocity of flow with a given percentage of loss of pressure per unit of length, the reason, of course, being that reduced pressure results in reduced friction against the pipe. The figures in Table A are the mean of those deduced by various authorities from the behaviour of fluids in pipes, and show the approximate maximum velocity of steam at various absolute pressures in pipes of sundry diameters with a loss of 1lb. pressure per 100ft. of length—a useful and convenient figure upon which to base a comparison, and a usual one in practice.

TABLE A.

Absolute pres., lbs. per sq. in.	Velocity of steam in feet per minute.							
2	12,000	17,500	24,000	29,000	34,000	38,000	42,000	61,000
20	4,000	6,000	8,000	10,000	12,000	13,000	14,000	17,000
150	1,600	2,300	3,100	4,000	4,700	5,400	5,800	6,500
200	1,400	2,000	2,600	3,200	3,800	4,200	4,500	5,000
Diam. of pipe..	1in.	2in.	4in.	6in.	8in.	10in.	12in.	18in.

The question of the diameter of steam and exhaust pipes for different horse-powers is one that has received a great deal of attention, and the general consensus of opinion appears to be that in the case of the former it is preferable for the pipe to be too small than too large, upon the score that the larger the pipe the greater its cost and that of its covering, and the amount of loss occasioned by condensation. The only argument for pipes of ample proportions is that the fall of pressure in them is negligible; but this cannot stand against the above disadvantages, besides which the pressure drop due to friction must not be entirely regarded as a loss, as the steam is to a certain extent superheated thereby, always a desirability even in a small degree. Exhaust pipes, upon the other hand, it is most important should be of ample dimensions, as back pressure, that will naturally decrease with the size, is a great source of lost energy acting under most favourable conditions for itself—namely, during the full length of the stroke, and on the engine piston of largest area. The increased cost with diameter of exhaust piping is not a matter of much consequence, and, at any rate, will be paid for over again in the saving effected by reduced back pressure.

A loss in steam-mains that is little appreciated is that which arises when several engines fed from one main pipe take their steam at the same instant of time. The result of such an event, which must be of frequent occurrence, is a momentary very large flow of steam in the pipe far beyond that which it was designed for, and a consequent drop of pressure by friction in excess of anything that would be tolerated in the usual way. The duration of the loss is, of course, very small, but seeing that it must recur with great frequency under ordinary conditions, it is one that is worth considering. A steam receiver placed at each engine, or perhaps at intervals in the main pipe, has long been advocated as a means of reducing this extra friction. Such an arrangement by providing a local reserve of steam that may be drawn upon in like cases to the above, not only helps to stop injurious vibration, but also saves much of the friction loss, and, as has been

Digitized by Google

proved, allows a smaller diameter of pipe to be used, thus compensating to a great extent for the extra condensation losses in the receiver. For best results it has been stated that the latter should have a capacity approximately of 50 times that of its engine's high pressure cylinder up to the point of cut off—an ample allowance, but apparently one that has been justified by the results obtained in practice. The usual system of installing separators at each engine is a step in the right direction, as these, besides performing their duty as steam driers, also act as small reservoirs, and tend to equalise the flow of steam in the pipe, although from the latter point of view they might be enlarged with advantage.

The question of the most suitable material for the construction of steam-pipes is one that in its time has given rise to much discussion, happily now terminated in the general admission that steel is far and away the best and safest metal for all-round purposes. Advocacy of copper has been based upon the fact that it is ductile and tough, and that it will to a great extent compensate for expansion within itself. It was adopted in marine work because its ductility allows it to bend freely with the straining of the ship without risk of fracture. These are in themselves undoubted advantages, but, on the other hand, copper pipes possess so many inherent defects, varying with the manner in which they are constructed, that their use with high-pressure steam is only advisable in most exceptional cases. The earliest copper pipes were built up of thin sheeting with a longitudinal brazed seam, the flanges also being brazed on. This method, however, introduces a very serious weakness, serious chiefly because it is one that takes time to come out. It has been found that though new brazed pipes will stand their hydraulic test perfectly and give every indication of reliability, the effect of heat and vibration is very deleterious to the brazing in time, depreciating it to such an extent that rupture along the seam may be anticipated ultimately almost with certainty. The solder used for this work consists of copper and zinc in approximately equal proportions, and as long as these proportions remain unaltered, the brazing may be regarded as sound and equal in strength to the pipe. It is found, however, that under the influence of high temperature and chemical action in time the greater part of the zinc disappears, only a little remaining in the shape of an oxide, with the consequence that the joint then depends solely for its holding upon a very cellular and brittle structure of copper, which is quite unsuitable for the purpose. This has been proved by chemical analysis of old brazing, and amply demonstrates that grave risks are incurred by the use of such piping. Up to diameters of 8in. or so it is now usual practice to make copper pipes seamless either electrically or by solid drawing. This certainly represents a considerable advance over the old method above referred to, but there are still salient objections that cannot be overlooked. As stated, the chief argument in favour of copper pipe is that its ductility allows the pipe itself to take up expansion and contraction, but this very quality is also greatly its undoing, since the repeated bending and straining that the pipe is subjected to in the processes hardens the metal very considerably by the flanges, with the result that it becomes brittle and loses the ductility that was the excuse for its adoption. When it has reached this stage, external vibration, such as may be occasioned by racing or water-hammer, is apt to result in radial cracking by the flanges, and that most fatal of all disasters—a burst steam-pipe.

From the various methods of reinforcement of copper pipes in use it is evident that those responsible for their installation are by no means over-confident as to their ability to stand severe strains when under the influence of high-pressure steam. A brazed copper pipe always gives out at the seam, and no matter how small the original opening may be, it will extend with increasing rapidity until it reaches the flanges each way. In order to confine such rips within less dangerous limits, various methods of reinforcement have been adopted; steel bands have been shrunk on or fixed in two halves by cotters at short intervals, varying with the size of the pipe and steam pressure; but it has been found that these, unless very closely spaced, actually weaken the pipe instead of strengthening it, and, in addition, they add considerably to radiation losses by increasing the surface. Another method is that in which a spiral copper band is wound round the pipe and brazed to it in order to equalise the strain, the ends being attached to the flanges by special means. The wire-wound pipe, such as is used in the navy, seems, however, the best of the bunch, as it is undoubtedly stronger, and being more closely applied cannot allow a burst to spread any distance. As a rule, two or more independent wires are used, so that in the event of one breaking, the other will still hold the pipe together. The wire is of copper or delta metal, wound on at a tension of 1½ tons per square inch, and is alone capable of withstanding the maximum pressure independently of the strength of the pipe.

While such methods may be effective, they cannot be deemed truly satisfactory in every sense, for besides adding largely to the prime cost and increasing the radiating surface, they are not always reliable, as experience has proved. Whatever excuse there may be for the use of copper pipes—reinforced or otherwise—at sea, there is none for them on land; and seeing that legally a steam-pipe now comes under the same heading as a boiler, and that engineers and managers are held responsible for any injury to life or limb that may occur through negligence in their upkeep, there is every advantage to be gained and nothing to lose by the complete abolition of copper pipe for high pressure or, perhaps, any steam work. However much opinion may differ with regard to this, there is unanimous agreement—in this country at least—that cast iron should be rigidly excluded from high-pressure pipework: 100lb. per square inch is the maximum pressure it should be used at, and even this is not desirable. The many bad accidents that have occurred with cast-iron elbows and T-pieces, owing to their brittleness and low elastic limit, have demonstrated the utter unsuitability of this metal for anything but low-pressure pipework, with the consequence that, copper being excluded by its expense and unreliability, engineers have turned to wrought iron and steel as the most suitable materials for use in connection with modern high pressures. Such pipes are usually either solid-drawn or lap-welded, sometimes in the latter case being strengthened by a reinforcement piece running longitudinally along the seam. Solid-drawn pipes are preferable, but welding makes a thoroughly sound job, and in ordinary cases does not need the above reinforcement strip, which introduces the possibility of leakage at the rivets. For 150lb. pressure, ¼in. is the usual thickness, and the hydraulic test generally specified is 350lb. per square inch

Steel and iron pipes having a lower coefficient of expansion than copper, require special expansion bends or joints where the range is of any length. In the interests of draining the first are best placed horizontally, and should be as thin as is compatible with safety in order to facilitate bending. Where expansion joints are used, it is essential that the pipes should be thoroughly anchored, and the joint, therefore, forced to take up variations in length. If this is not done, it is quite possible that the special piece moving hard on its gland may throw the work on the flange joints, and so cause the leakage and strains that it was installed to prevent. The adjustment of these joints is a delicate matter, and forms the chief objection to their use, it being difficult to hit the point where leakage at the stuffing box is reduced to a minimum and free movement is not interfered with. A bunch of small pipes in parallel inserted at intervals in the main range has been effectively used for taking up expansion, but the increased number of joints that this system necessitates is a drawback, besides the difficulty in covering. On the whole, the horizontally placed bend has given the greatest satisfaction, being, if properly designed, certain in its action and perfectly safe.

The flange of mild-steel and malleable iron pipes are made of the same materials stamped out of the solid, and are usually provided with strengthening collars. Up to 6in. diameter it is general practice to fix them on the pipe when hot by means of a fine thread, expanding, caulking, and brazing being used as additional safeguards. Over this diameter they are generally riveted, holes being drilled radially to the centre of the pipe after the flange is in position, the burrs removed, and the rivets driven by hydraulic pressure. The best practice always provides for an

Digitized by Google

accurately faced strip for jointing purposes, standing out $\frac{1}{16}$in. or $\frac{1}{8}$in. from the flange, and level with the end of the pipe. With screwed flanges, especially if the thread employed is coarse, there is always a possibility of leakage between the flange and the pipe, and the best way to obviate this is to make the joint upon the end of the pipe as well as on the flange, and not wholly on the latter. With small pipes it is not as important or as easy a matter to do this, and consequently accurate facing all over of the flange is the method employed, but with larger diameters the pulling up so distorts the flanges as to render the greater part of their surfaces useless for the prevention of leakage, which has to be guarded against by the narrower joint nearer the pipe where the strains do not take effect.

With well-erected pipes and good facing strips a soft copper ring makes an excellent joint, but is rather difficult to fix accurately in position. The corrugated brass ring smeared with mastic cement is easy to apply, and makes an equally good joint, and its use may be said to be almost universal for both high and low pressure work. Owing to the distortion that takes place in flanges by the pulling up of the bolts, it is most necessary that the bolt circle should be as small as possible; putting aside the enhanced difficulties of jointing, the more a flange is distorted the greater is the risk of its giving out. With a small bolt circle—that is, one that only just allows room for the bolt-heads and nuts—the leverage of the power that tends to pull the flange out of its plane is reduced, while at the same time the pressure on the jointing material is exactly the same; thus a small circle represents the best possible conditions obtainable. British and American standard practice in flanges is contrasted in Table B.

TABLE B.

Bore. In.	British. Dia. of flange. In.	British. Dia. of bolt circle. In.	British. No. of bolts.	British. Size of bolts. In.	American. Dia. of flange. In.	American. Dia. of bolt circle. In.	American. No. of bolts.	American. Size of bolts. In.
2	7	5½	6	⅝	6½	5	4	⅝
2½	7½	6	6	⅝	7½	5⅞	4	¾
3	8¼	6¾	6	¾	8¼	6½	8	⅝
3½	9	7¼	6	¾	9	7¼	8	⅝
4	10	8¼	8	¾	10	7⅞	8	¾
5	11	9	8	¾	11	9¼	8	¾
6	12	10	8	¾	12½	10⅝	12	¾
7	14	11¾	12	¾	14	11¾	12	⅞
8	14	12¼	12	¾	15	13	12	⅞
9	15	13¼	12	¾	16	14	12	⅞
10	17	14¾	12	⅞	17½	15¼	16	⅞
12	19½	17¼	12	⅞	20	17¾	16	⅞

It will be noticed that in American practice the number of bolts employed is always a multiple of four, whereas in England the six-bolted flange is a very popular one in medium sizes. The English bolt circle is smaller in large pipes than the American, but the reverse in small sizes, and the diameter of the bolts varies in much the same way.

TELEPHONE RATES AND GOVERNMENT PURCHASE.

The following is a statement on the above subject prepared by Mr. A. R. Bennett, dated December, and addressed somewhat widely—*i.e.*, "to local authorities, chambers of commerce, trade associations, and others interested in the provision of a good and cheap telephone service":

The following is a statement, compiled from published rate lists and advertisements, of the National Telephone Company's tariffs in towns where competition exists or has existed. The most noteworthy points are the £5 per annum exclusive line, with unlimited number of calls, for private houses at Hull, and the suppression of the £10 and £8 10s. unlimited rates at Portsmouth and Swansea. Where corporation competing exchanges exist their tariffs are also given.

Many of the tariffs have been in operation for years—that at Sheffield for about 12 years, and those at Glasgow, Tunbridge Wells, and Portsmouth for from two to three years—and they are still vigorously pushed. They cannot, therefore, be taken as experimental rates, but rather as representing what are remunerative rates to the company, and what British cities and towns can be telephoned for. There is danger that the Post Office in carrying out the contemplated purchase of the telephones may pay such a price as to make any cheapening of telephony in the United Kingdom impracticable, thereby placing British manufacturers and traders permanently at a disadvantage as compared with their competitors in foreign countries, where cheap telephone rates prevail. They are already so in respect to telephone trunk-line rates, as those charged by the British Post Office have no parallel elsewhere in Europe. Foreigners are also free from the terminal charges which the National Telephone Company is permitted to impose on trunk messages exchanged between its subscribers and those of the Post Office and corporations.

At different times the Corporations of Hull and Eastbourne have negotiated for the purchase of the company's system in their respective areas, but both found that the price demanded for the old plant was about three times the cost of an entirely new exchange. Purchase on such terms was out of the question, as it would have precluded the possibility of giving their burgesses lower rates. It is unlikely that the company will sell to the Post Office except on some such favourable terms: it can scarcely ask its shareholders to write off a proportion of their holdings, and as many have bought into the company at 106-8 for the purpose of making a profit out of the anticipated sale, it is improbable that they would agree even if asked. Consequently, there is a likelihood of the Post Office recommending Parliament to buy at a price that would burden the public with high rates in perpetuity. It is true that a select committee has been promised, but no terms of reference have been mentioned, and it is by no means certain that it is intended that the committee shall take evidence and sift matters to the bottom.

It therefore behoves local authorities, chambers of commerce, trade associations, and kindred bodies throughout the kingdom to take concerted action to impress upon the Government that any purchase of the telephones would be useless unless it could be arranged beforehand to ensure that the low rates proved to be practical by the corporations and by the company itself, as demonstrated by its published tariffs, can be made universally applicable. It would be suicidal to agree to a price without ascertaining definitely what scale of rates that price would render practicable. The Post Office makes a recurring loss on the telephone business which it at present conducts. The Treasury after a purchase would certainly insist on rates that would produce a profit on the purchase price, and so, unless foresight be exercised, telephone users may have their rates raised instead of reduced. Further, if no purchase takes place, it should be made a condition of any prolongation of the company's license which may be granted in any part of the kingdom, that the reduced rates now in force at Glasgow, Hull, etc., be brought into immediate use universally and permanently.

A secondary point for consideration and investigation is why the company's telephone charges differ so materially in different places. Why should it charge so much lower in Glasgow than in Huddersfield, in Hull than in Edinburgh, in Portsmouth and Brighton than in Southampton and Ramsgate, and in Swansea than in Cardiff?

It is remarkable that no distance limit is imposed on any of the rates, low as they are, except at Sheffield and Tunbridge Wells. This is another inequality between competitive and non-competitive towns which calls for redress.

Wherever there is competition, too, the company reorganises its system, modernises its apparatus, and spares no expense to meet its subscribers' wishes. It opens public telephone call offices everywhere. In Glasgow it now has over 1,000 such offices, whereas before the competition there were only some dozen or so.

It should be understood that the corporation tariffs are remunerative. In no cases are corporation exchanges being run at a loss, while they continue to grow in spite of all opposition.

A. R. BENNETT.

Particulars of Telephone Charges.

Glasgow Telephone Area (Population, 1,000,000).

National Telephone Company.

1. Exclusive Line.—Unlimited use, £10 a year first connection. Second connection, £8. 10s. a year.
2. Two-Party Line.—Unlimited use, £6 a year.
3. Exclusive Line.—Measured service, £5 a year, 600 calls. Excess calls 1d. each, or 300 for £1.
4. Four-Party Line.—Unlimited use, £4 a year.
5. Ten-Party Line.—No installation charge, subscriber to guarantee 2d. a day (payment for two calls). Extra calls, 1d. each.
6. Omnibus Line.—25s. a year for 600 outward calls. Excess calls, ½d. each.
7. Special Exclusive Line for private houses, £5 for 1,500 calls. Excess calls, 1d. each.
8. Extension Station in the same building as the main station.—On a message rate line, 15s. a year. On a flat rate line, £1 a year. Special terms to large users. All inward calls are free.

Corporation.

Exclusive Line.—Unlimited use, £5. 5s. per annum.
Toll Service.—Exclusive line £3. 10s. per annum and 1d. for each outward call.
Two-Party Line.—Unlimited use, £4. 4s. per annum.
Four-Party Line.—Unlimited use, £3. 3s. per annum.
All inward calls are free.

Hull Telephone Area (Population, 300,000).

National Telephone Company.

Exclusive Line.—Unlimited service, first connection, £10 per annum. Second connection, £8. 10s. per annum.
Private houses, £5 per annum. Exclusive line, unlimited service.
Rates for large users:
10 or more exchange lines, £7 per line per annum.
15 or more exchange lines, £5. 10s. per line per annum.
Line to be used for trunk-line connections only, £5 per annum.
Exclusive Line.—Measured service:

600	messages,	£5 per annum.
1,100	,,	£6 ,,
1,600	,,	£7 ,,
2,100	,,	£8 ,,
2,600	,,	£9 ,,

Extra messages, 1d. each.
Message rate service, £3 per annum and 1d. per message.
Two-Party Line.—No installation charge, subscriber to guarantee 4d. per day (payment for four messages). Extra messages, 1d. each, or Unlimited service. £5 per annum.
Four-Party Line.—Unlimited service, £4 per annum.
Ten-Party Line.—No installation charge, subscriber to guarantee 2d. per day (payment for two messages). Extra messages, 1d. each.
Omnibus Line.—25s. per annum for 600 messages. Extra messages, ½d. each.
Extension Lines.—Extension station in the same building as the main station. On a message rate line, 15s. a year. On a flat rate line, £1 a year.
All inward calls on all services are free.

Corporation.

Exclusive Line.—Unlimited use:
For business premises, £6. 6s. per annum.
For business premises (second connection), £5. 15s. per annum.
For private houses, £5 per annum.
Toll Service.—Exclusive line, £3 per annum and 1d. per outward call.
All inward calls are free.

Portsmouth Telephone Area (Population, 250,000).

National Telephone Company.

No mention is made of any £10 or £8. 10s. unlimited rate.
1. Exclusive Line.—Measured service:

£5	0	0	a year providing	1,800	messages.
£5	10	0	,, ,,	2,500	,,
£6	0	0	,, ,,	3,000	,,
£7	0	0	,, ,,	3,500	,,
£8	0	0	,, ,,	4,200	,,
£9	0	0	,, ,,	5,000	,,

Extra messages, ½d. each.
2. Exclusive Line.—Message rate, £3. 10s. a year, and ½d. a message.
3. Two-Party Line.—Unlimited use, £3 a year.
4. Ten-Party Line.—No rental. Subscriber to guarantee to originate on an average 1d. call a day.

Corporation.

Exclusive Line.—Unlimited use, £5. 17s. 6d. per annum.
Exclusive Line.—Unlimited use, second connection, £5. 5s. per annum.
Exclusive Line.—Toll tariffs:
1. £3 10 0 per annum, with ½d. for each outward call.
2. £2 10 0 per annum, with 1d. for each outward call.
3. £5 0 0 per annum to cover 1,800 outward calls. Extra calls, ½d. each.

All inward calls are free.

Tunbridge Wells Telephone Area (Population, 70,000).

National Telephone Company.

Exclusive Line.—Unlimited service, £6 per annum.
Message Rate.—£3. 10s. per annum, and 1d. per outward call. Subscribers to guarantee a minimum payment of 30s. per annum, and to deposit that amount as security.
Ten-Party Line.—No annual payment. Outward calls, 1d. each. Subscriber to guarantee a minimum of 2d. per day. Money collected in slot machine.
Two-Party Line.—Same as ten-party line, but subscriber must guaran a minimum of 4d. per day.
All inward calls are free.

Foregoing rates for exclusive lines apply to one mile from the exchange only, and in the case of party lines to 220 yards from a main circuit.

The low rates in the Tunbridge Wells area were brought about by the establishment of a municipal telephone exchange, which, after being in successful operation and paying its way for a few months, was sold to the National Telephone Company. While the Corporation obtained several thousand pounds more than their exchange had cost, and secured permanent and substantial reductions on the tariffs which had prevailed prior to competition, it is obvious from an inspection of the present National Telephone Company charges that the Tunbridge Wells people are far worse off, both as regards tariffs and restrictions, than those of Glasgow, Portsmouth, Brighton, and the other places which have kept their own exchanges.

Brighton Telephone Area (Population, 185,000).

National Telephone Company.

Exclusive Line.—Unlimited service, first connection, £10 per annum. Second and additional connections, £8. 10s. per annum.
Exclusive Line.—Limited service, £3. 10s. per annum, plus ½d. per call.
Exclusive Line.—Measured service:

£5	0	0	per annum with	1,600	free calls.
£5	10	0	,, ,,	2,500	,,
£6	0	0	,, ,,	3,000	,,
£7	0	0	,, ,,	3,500	,,
£8	0	0	,, ,,	4,200	,,
£9	0	0	,, ,,	5,000	,,

Additional calls, ½d. each.
Two-Party Line.—£3 per annum, with unlimited service.
Ten-Party Line.—No installation charge. Subscriber to guarantee 1d. per day (payment for one local call).
Omnibus Line.—25s. per annum for 600 calls. Extra calls, ½d. each.
All inward calls are free.

Corporation.

Exclusive Line.—Unlimited use. £5. 10s. per annum.
Exclusive Line.—Toll service, £3. 10s. per annum, with 1d. for each outward call.
Party Lines:
Two-party, unlimited use, £4. 4s. per annum.
Four-party ,, ,, £3 ,,
All inward calls are free.

Swansea Telephone Area (Population, 150,000).

National Telephone Company.

No mention is made of any £10 or £8. 10s. unlimited rate.
Exclusive Line.—Measured service:

1,800	messages	£5	0	0 a year.
2,500	,,	5	10	0 ,,
3,000	,,	6	0	0 ,,
3,500	,,	7	0	0 ,,

½d. for each additional outward message.
Exclusive Line.—Message rate, £3. 10s. a year, and ½d. per message.
Two-Party Line.—Unlimited use, £3 a year.
Ten-Party Line.—Subscribers to guarantee 1d. per day (payment for one message). Extra messages, 1d. each.
Omnibus Line.—600 messages, £1. 5s. a year. Extra messages, ½d. each.
All inward calls are free.

Corporation.

Exclusive Line.—Unlimited use, £5 per annum.
Exclusive Line—Toll tariff, £3 per annum, with 1d. for each outward call.
All inward calls are free.

Sheffield, City and Suburbs (Population, 427,000).

National Telephone Company.

Business premises within 1½ miles of an exchange, £8 per annum.
Business premises within two miles of an exchange, £10 per annum.
Private houses not exceeding two miles from an exchange, £7 per annum.

The low charges in Sheffield were brought about by the threatened competition of the New Telephone Company in 1892. A committee of Sheffield citizens was formed to arrange for such competition, to avoid which the National Telephone Company agreed to introduce and permanently maintain the tariff as noted.

Guernsey (Population, 40,300).

National Telephone Company.

The company has no exchanges in Guernsey. In order to start one it asked £10 per line per annum, with extras for distances beyond one mile; when the local authority threatened to undertake the telephoning of the island themselves the £10 was reduced to £8. When it became apparent that the local authority were in earnest this £8 was further reduced to £6, with other concessions thrown in, but the States declined to be turned from their purpose, although the last offer would probably have been accepted had it been made in the first instance.

States (Local Authority).

The States established their exchange in 1898, and it is now scoor ingly in its seventh year of working. The following are the tariffs, which yield a satisfactory profit. All lines are direct to the exchange and exclusive.
1. £5 per annum to cover 4,000 outward calls; additional calls, five for 1d.
2. £2. 10s. per annum and ½d. for each outward call up to 1,520; additional calls, five for 1d.

Digitized by Google

3. £1. 10s. per annum and 1d. for each outward call up to 1,000; additional calls, five for 1d.
All inward calls are free.

TRADE NOTICES AND NOVELTIES.

Electrical Apparatus.

Several fine examples of switchboard work are illustrated in the latest catalogue issued by Messrs. Dorman and Smith, Ordsal Electrical Works, Salford, Manchester, besides some up-to-date specialities shown now for the first time. Liquid controllers are listed for reversing series or compound wound crane motors, etc., and also non-reversible controllers for starting motors in the ordinary way. We illustrate herewith (Fig. 1) one of the non-reversing pattern. The principal feature

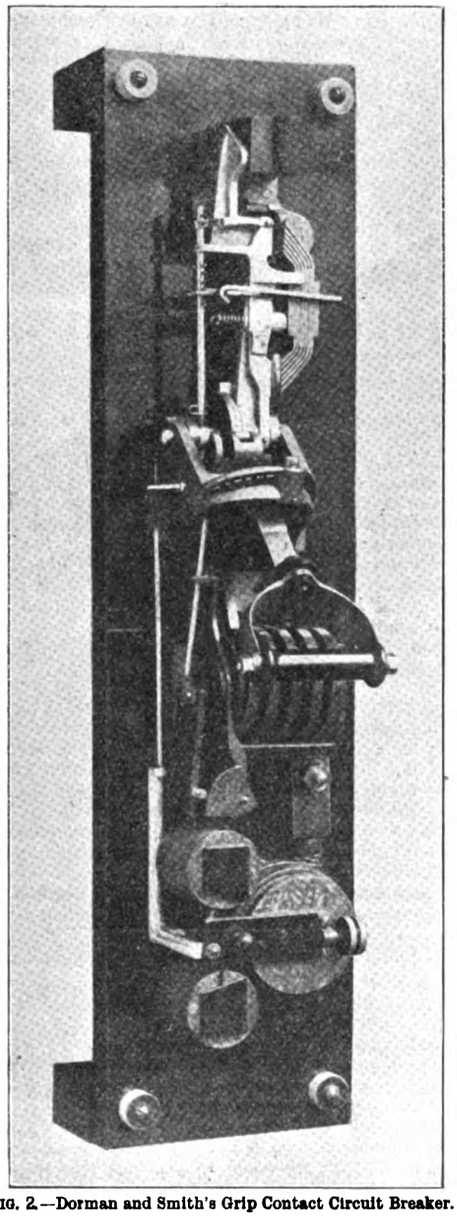

FIG. 2.—Dorman and Smith's Grip Contact Circuit Breaker.

carried out in this liquid motor starter is the provision of ample area of plate and an efficient short-circuiting switch for when the plate is fully immersed. Moreover, great care has been taken to secure perfect insulation, the chief cause of trouble met with in using this class of apparatus being thus eliminated. Our next illustration (Fig. 2) shows one of the firm's patent "grip-contact" circuit breakers. This is a combined overload and reverse-current circuit breaker for direct current. The edgewise construction and very substantial design of the controlling gear will be noted. Messrs. Dorman and Smith have always made the controlling device of their circuit breakers with a large reserve of power. This they claim is the principal reason why these breakers are so free from the defects of failure to act. Fig. 3 shows the firm's double-pole "Baffle" type of house service fuse. The fuse contacts are disconnected when the lid is opened, and the fuse can thus be replaced while the contacts are depolarised. The fuse itself passes over a baffle plate provided with an asbestos pad which effectually prevents arcing between the terminals when the fuse blows. The live terminal, which is the lower one shown in the illustration, is quite cut off from the fuse itself. These fuses are made with self-contained ceiling boxes, or with sepa-

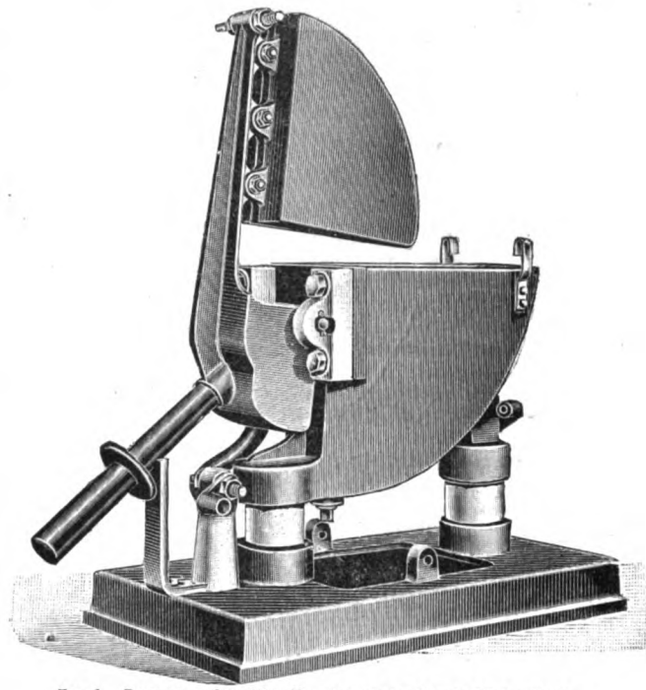

FIG. 1.—Dorman and Smith's Non-Reversible Liquid Motor Starter.

rate ceiling boxes as required. Altogether, their design seems admirable. From the large range of fittings listed in the latter portion of the catalogue we select one of the mill fittings (Fig. 4) as an example. These fittings have been designed

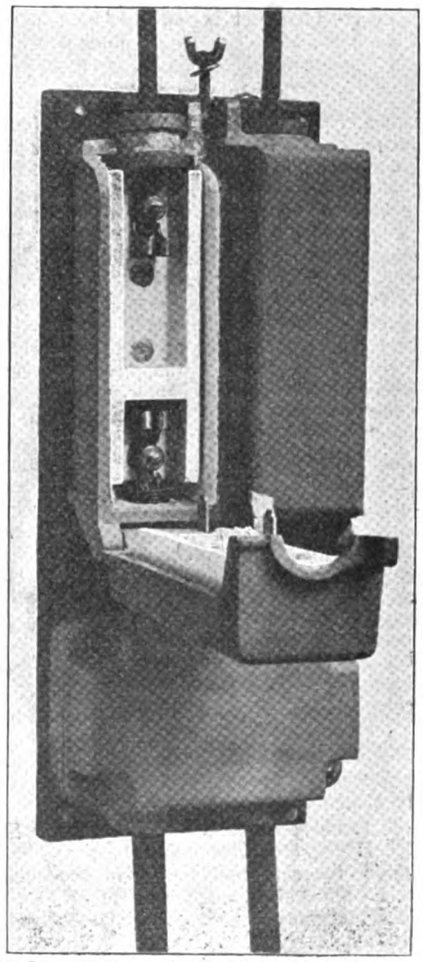

FIG. 3.—Dorman and Smith's Double-Pole Baffle Fuse.

to be interchangeable with the patent conduit wiring ceiling roses, the same jointing box being used for either a ceiling rose or one of the mill fittings as may be required. The jointing boxes are constructed for any make of conduit, and for one, two, three, or four ways.

Digitized by Google

Among the further contents we notice improved chopper switches and various replacement fuses, which can be supplied either mounted or unmounted for the use of switchboard makers; improved ceiling plate and other accessories for nexpensive pipe wiring; iron-cased switch and fuse gear, and

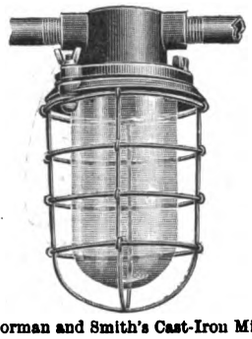

FIG. 4.—Dorman and Smith's Cast-Iron Mill Fitting.

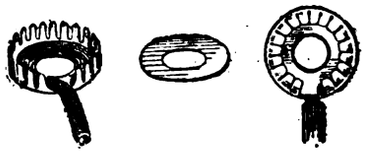
a new small-size porcelain tumbler switch. Incidentally, it may be mentioned that improved facilities for production and increased output have enabled Messrs. Dorman and Smith to make substantial reductions in their prices, while at the same time maintaining the high quality of their manufactures.

Terminals.

Messrs. Ross, Courtney, and Co., Limited, Ashbrook-road, Upper Holloway, London, N., have sent us a sample box of their new patent terminals for small wires. The accompanying illustration shows the principle involved. The end of the



wire is looped into the terminal, a washer laid on the top, and the serrated edges of the terminal then pressed down with the fingers. Thus a good contact is made without destroying the flexibility of the wire, while the use of pliers or other tools for the job is unnecessary.

Catalogues, etc.

MOTORS FOR INTERMITTENT SERVICE.—The Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C., have sent us a copy of their list No. 20, in two sections, A and B, dealing with continuous-current series-wound motors designed for intermittent service and for driving machines which only start under load, and which frequently require a reversal of their motions. The cases of these motors are divided horizontally in line with the shaft. The lower half is provided with cast-iron feet, and carries the oil-wells for ring lubrication, also the terminal block. Thus, by unbolting the top half of the motor case, it becomes possible to make a convenient and close inspection of the inner parts of the motor. Some useful advice on the selection of motors for various purposes is included in Section A of the list under notice, while Section B is composed for the most part of tabulated data.

SIEMENS ELECTRIC APPLIANCES.—From Siemens Electric Appliances, Limited, 61-62, Watling-street, London, E.C., we have two leaflets, the first of which deals with the firm's traction lamps, especially made for series burning, and the second with their economical turn-down lamps.

POLYPHASE GENERATORS. — Messrs. Mather and Platt, Limited, of Salford Ironworks, Manchester, and Queen Anne's-chambers, Westminster, S.W., have recently published a second edition of their list of standard generators for two-phase or three-phase currents. These generators are of the revolving-field type, and range in output from 75 to 1,500 kilovolt-amperes. Their design is based upon the considerable experience in the construction of alternating-current machines generally which Messrs. Mather and Platt, Limited, have had, and the careful study of requirements. For further particulars we must refer the reader to the list in question.

ELECTRIC MINING.—Messrs. John Davis and Son, of All Saints' Works, Derby, and Camomile-street-chambers, London, E.C., favoured us recently with a copy of the latest edition of their Section B catalogue, entitled electric mining. This publication deals largely with coal-cutting machines and other plant used in mines. Colliery fittings, mining bells, telephones, etc., are also listed.

AUTOMATIC BATTERY SWITCHES.—A leaflet which we have received from Ernest F. May, Limited, Greenland-place, Camden Town, London, N.W., describes the firm's automatic battery switch, type No. 67. This switch automatically closes the circuit when the E.M.F. of the dynamo exceeds that of the cells, and opens it in the event of the charging volts falling below the battery volts. It is enclosed in a neat enamelled cast-iron case, with a hinged front fitted with a glass panel, so that the action of the swich may be observed, being suitable for mounting on a main switchboard or fitting in a battery-room. Five sizes are listed, ranging in capacity from 30 to 150 amperes.

ACCESSORIES. — From the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C., we have several new leaflets dealing respectively with high-voltage lamp-holders and adaptors; tumbler switches and wood blocks; Royal switches of different patterns, including change-over switches, switches in watertight cast-iron cases, and single-pole pear switches; H.V. wall sockets and plugs; ceiling roses and fuseboards. The same firm also send us a pamphlet describing their "Ideal" candle fitting.

Calendars, etc.

CALVERT'S MECHANICS' ALMANACK AND WORKSHOP COMPANION.—Forty-second year of publication. Wm. Calvert, Gordon-street, Old Trafford, Manchester.

UNITED STATES METALLIC PACKING COMPANY, LIMITED, Soho Works, Bradford.—An artistic bas-relief calendar.

WILLING'S PRESS GUIDE, 125, Strand, W.C., and 162, Piccadilly, W.—The thirty-second annual issue of this handy "Press Guide" is quite up to the excellent standard of its predecessors.

RHODES ELECTRIC MANUFACTURING COMPANY, LIMITED, 70 and 71, Bishopsgate-street Within, London, E.C.—A fantastic Christmas card.

LEGAL INTELLIGENCE.

THE CITY AND SOUTH LONDON RAILWAY COMPANY v. THE RECTOR AND CHURCHWARDENS OF THE UNITED PARISHES OF ST. MARY WOOLNOTH AND ST. MARY WOOLCHURCH HAW AND THE ECCLESIASTICAL COMMISSIONERS FOR ENGLAND.

This case came before the House of Lords on an appeal from an order of the Court of Appeal dated March 27, 1903, affirming an order made by Mr. Justice Wright on May 14, 1902, made upon an award stated in the form of a special case for the opinion of the Court by Robert Vigers, the arbitrator appointed therein. The question was the amount of purchase money or compensation payable by the appellants for certain land adjoining and annexed to the Church of St. Mary Woolnoth, and for an easement or right of using the subsoil, crypt, and foundations of the church which had been taken by the appellants.

The case was fully argued by counsel.

The **Lord Chancellor**, in moving that the appeal should be dismissed, said that the company had not paid for the value of the site, but had only been called upon to pay for that which they had actually obtained. The extra expenditure below the foundations of the church had been deducted from the sum which they had been called upon to pay. If in the future the church should be removed, there was no reason why the respondents should not be compensated for what was their own property. The Court of Appeal had dealt with the questions involved with perfect accuracy.

Lord Macnaghten, Lord Robertson, and **Lord Lindley** concurred.

THE DEPTFORD AND GREENWICH TRAMWAYS.

In the King's Bench Division on Wednesday, Mr. Justice Bray delivered judgment in the case of the London, Deptford, and Greenwich Tramways Company and the London County Council. The Council having given notice to acquire the London, Deptford, and Greenwich tramways, Mr. H. G. Harris was appointed referee by the Board of Trade to decide the value of the undertaking. During the arbitration a contention was raised by the company that the present value of the tramways was enhanced by reason of the company being freed from liability to contribute to the widening of some of the streets in which the tramways were laid. The referee held that the contention of the company was unfounded. The widenings had not, in fact, been made.

His Lordship said that to him it was a startling proposition that the Council should have to pay as part of the purchase money for an expenditure which had never been incurred. Admittedly, the claim was a novel one, and there was no authority to support it. He had come to the conclusion that the referee was right when he expressed the opinion that the contention of the company was wholly unfounded. The company's contention could not prevail, and therefore it was entitled to only £91,363. 7s. 6d., and not to the additional £22,773. 6s. 8d.

PERSONAL.

The partnership between Mr. Vincent S. Allpress, M.I.C.E., consulting electrical and mechanical engineer, and Mr. W. H. Massey has been dissolved by mutual consent. Mr. Allpress will continue to practice at 25, Queen Anne's-gate, Westminster.

Mr. H. H. Heayberd, late of Messrs. R. W. Blackwell and Co., has been appointed outside equipment assistant at the tramway power station, Osborne-street, Hull.

COMPANIES' MEETINGS AND REPORTS

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS.

The ordinary general meeting was held at the office, Cannon-street, Major Leonard Darwin presiding. Particulars of the account appeared in our last issue.

The **Chairman** stated that the present price of raw material was very high; raw indiarubber was about 30 per cent. higher than the highest ever reached before, and twice the price at which it had been sold at a fairly recent date. About 10 days ago the trade agreed to advance selling prices, but the increase would not suffice if the price of the raw material should not show a considerable reduction in the current year. The development of a new line of business was progressing, and the inevitable attendant expenses, though diminishing, were still very heavy, and had made serious inroads into such reserves as were applicable to this purpose, and also on the year's revenue. Increased vigilance and great prudence were necessary on the directors' part owing to the ever-increasing, though only too often ephemeral, competition to which the Company's productions were subjected. Local taxation was another point which industrial undertakings should always have in view. Their rating in West Ham, where the Silvertown works were situated, had reached 10s. 2d. in the £. As a rate of about this amount had been charged for some years, he believed that the establishment of their works in the district brought a contribution of no less than between £45,000 and £55,000 per annum to the Corporation. The Board were of opinion that in present circumstances it was unwise to ask the shareholders to sanction the payment of a larger dividend than 5 per cent. for the year.

The resolution adopting the report, which recommended a dividend of 5 per cent., was carried.

SOUTH STAFFORDSHIRE TRAMWAYS.

The fourteenth ordinary general meeting of this Company was held at Winchester House, Mr. W. Somers L. Schuster, the chairman, presiding.

The **Chairman** stated that the Company had been in conflict with various bodies, but he was glad to say they had come to a settlement with the lessee company. The offer made by the lessee company in a circular of July 1, 1904, had been accepted by proprietors holding £77,405 ordinary stock and £58,240 preferred capital, which represented a very considerable majority. The lessee company was now very much the largest shareholder in the old concern, and it was just as much in their interest as in that of the other shareholders to do all that was possible with the Company. The lessee company's nominees were people who thoroughly understood the tramways business from every point of view; there was no body which controlled more tramways in the United Kingdom than the British Electric Traction Company. They had a total of £1,590 available for distribution, and out of this it was proposed to devote to dividends a sum of £1,583, which left the very small sum of £7 to carry forward. This meant a dividend of 2s. 10d. for the year 1903, and one of 1s. 4d. for the half-year ending June 30 last. In regard to the various negotiations which they had had with the local authorities, the completion of the sale of that part of their undertaking in the borough of Wednesbury still remained in abeyance; the sale to the Handsworth Urban District Council of the lines and depôt in Handsworth had been completed at the price mentioned last year; while negotiations were still pending with the Corporation of Dudley regarding the purchase by them of that part of the undertaking in that borough. All these negotiations would be greatly helped by the lessee company holding such a large proportion of the shares, for all interests would be in harmony, and it would practically be a dual control.

The report was adopted.

ISLE OF THANET ELECTRIC TRAMWAYS AND LIGHTING.

The annual meeting of this Company was held at Winchester House, Lord Arthur Butler presiding.

In moving the adoption of the report, the **Chairman** stated that the total receipts showed an increase of £2 943 when compared with the previous year's account. The increased traffic had been largely due to the improved weather during the summer season. The total mileage run showed an increase of 48,967, and the number of passengers an increase of 226,490. To pay the debenture interest, dividend on preference shares, interest on loan, income tax, etc., an additional sum of £2,454 was required, and this had been taken from the unappropriated balance at the credit of last year's revenue account. **Mr. H. Brown** seconded the adoption of the report, which was approved.

MANX ELECTRIC RAILWAY.

The report for the year ended Sept. 30, 1904, to be submitted at the meeting on the 3rd prox., states that gross receipts amounted to £30,818, and expenditure to £17,279, leaving a net profit of £13 538. To this must be added balance brought forward from last year, £3,266. After paying the preference share dividend there remains to be carried forward £780. During the year a large amount has been spent out of revenue in raising and ballasting the Douglas and Laxey track and also the Snaefell Mountain track, and the whole line has been kept in a good state of repair. Upon capital account there has been expended during the year £20,414 in the completion of the new generating plant and equipment, on rolling-stock, the erection of car-sheds, goods-sheds, and other works. The sum of £1,000 has, in addition, been set aside out of revenue towards a renewal fund.

NEW COMPANIES REGISTERED.

Dorchester and District Electric Supply Company, Limited.—Capital, £1,000. Objects: to construct, lay down, establish, and maintain cables, wires, lines, accumulators, lamps, and works, and to carry on the business of electricians, electrical and general engineers, suppliers of electric light and power, tramway proprietors, etc., in Dorchester or elsewhere. Registered office: 11, Carteret-street, Queen Anne's-gate, Westminster.

Marlborough Electric Supply Company, Limited.—Capital, £1,000. Objects: to carry on the business of suppliers of electric light and power, electrical engineers, electricians, contractors, tramway and railway proprietors, etc., and to enter into an agreement with the Bristol Trust, Limited, whereby the said trust undertakes, in consideration of £250, to pay the costs of formation and registration and certain preliminary expenses.

Automatic Electric Company, Limited.—Capital, £1,000. Objects: to carry on the business of suppliers of light, heat, and power, carriers of passengers and goods, manufacturers of telephones, telegraphs, phonographs, dynamos, accumulators, lamps, and all apparatus used in connection with the generation, accumulation, distribution, supply, and employment of electricity, etc. No initial public issue. D. L. Chalmers is the first managing director. Registered office: 12, St. John's-lane, Liverpool.

Kramos, Limited.—Mr. H. V. Kramer has formed a new company under the style of Kramos, Limited, Bath, with the object of taking over the entire business of the late Bath Manufacturing Company, Limited, for the manufacture of Kramos controllers, resistance pieces, high-speed electrical drills, etc.

Liens Registered.

City of Buenos Ayres Tramways Company (1904), Limited, London, E.C.—Trust deed registered Dec. 8, for £174,000 4 per cent. debenture stock. Trustees: J. Heaton, 1, Great Winchester-street, E.C.; S. Rostron, of Beddington; and E. H. Woods, 110, Cannon-street, E.C. Secured on an annuity for 80 years of £71,060, reducible to £70,660, the sum of £11,500 to be invested, and the interest thereon and all accumulations thereon referred to in the trust deed as the redemption fund, and on the undertaking, assets, and property, present and future.

Liverpool Electric Cable Company, Limited.—Debenture registered Dec. 12, for a sum not exceeding £6,000. Holder: Liverpool Rubber Company, Limited. Charged on the undertaking and all the property, present and future, including the uncalled capital for the time being.

APPOINTMENTS VACANT.

Electrical Engineer, Hanley Corporation. Salary £300, rising to £350 by annual increments of £10. Applications to Town Clerk by Jan. 10. See advertisement.

Improver, Perth Corporation electricity works. Wages, 12s. per week. Applications to John Lambert, burgh electrical engineer. See advertisement.

Foreman Instrument Maker, small shop in the North of England. See advertisement.

Electrician for electrical department. Apply, by letter, to Thomas Broadbent and Sons, Limited, Central Ironworks, Huddersfield. See advertisement.

Publicity Department Manager, electricity works, Croydon. Salary, £150 per annum. Applications by Dec. 27 to Borough Electrical Engineer.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Spain.—Particulars of tramway concessions appear in another column.

Guirgia (Roumania)—Tenders are required for the electric lighting of the town. Particulars from the town's secretary. Tenders by Jan. 28, 1905.

Neath.—The Corporation invite tenders for the supply and delivery of electric wattmeters. Specification on application to the Town Clerk. Tenders by Dec. 28.

Caen (France).—The Prefect requires tenders for concession of a tramway from Ryes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1, 1905.

Rochdale.—The Corporation invite tenders for high-tension three-phase switchgear and extensions to the low-tension continuous-current switchboards. Tenders to Mr. Wm. Henry Hickson, town clerk, by 27th inst.

Sunderland.—The Corporation invite tenders for the supply of one wooden cooling tower capable of cooling the circulating water for a surface condenser dealing with 30,000lb. of steam per hour. Tenders by Dec. 30.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Digitized by Google

Port Elizabeth.—Messrs. Davis and Soper, 54, St. Mary-axe, E.C., agents of the Municipal Corporation of Port Elizabeth, South Africa, invite tenders for various works in connection with the Corporation electricity supply undertaking Tenders by Jan. 16, 1905.

Pudsey.—The Corporation invite tenders for underground electric mains, switchboard, etc. Specifications, etc., may be obtained on application to Messrs. Shepherd and Watney, consulting engineers, Greek-street-chambers, Leeds. Tenders to the Town Clerk by Jan. 20.

Erith.—The Urban District Council invite tenders for overhead line equipment, poles, etc.; underground feeder cables, boxes, etc.; rotary converters, transformers, and motor-booster; and main high and low tension switchboards, cable connections, etc. Tenders by Jan. 9. See advertisement.

Johannesburg.—The Municipal Council invite tenders for two 35-ton electric overhead travelling cranes and transformer pillars and switchgear. Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W., and received by them not later than Dec. 27.

Spain.—The *Gaceta de Madrid* of Dec. 6 notifies an application by the Compañia General de Tranvias for the concession of an electric tramway from Sans to Coll-Blanch. One month from the date of the publication of this notice is allowed in which other proposals on more favourable terms, duly guaranteed, may be made. The *Gaceta* may be seen at the Commercial Intelligence Branch of the Board of Trade.

Hull.—The Public Libraries Committee invite tenders for the necessary electric light installation and fittings required at the Carnegie Library, West Park, Anlaby-road. Specifications may be obtained at the office of Mr. Joseph H. Hirst, city architect, Town Hall, Hull. Tenders are to be addressed to the Chairman of the Libraries Committee, and delivered at the Town Clerk's Office, Hull, before 10 a.m. on Jan. 2.

Valladolid.—Tenders are required for the public lighting by means of electricity of the city of Valladolid. Fifteen hundred incandescent lamps of 17 c.p. will be required. The concession will terminate on Dec. 31, 1911. The annual payment to the concessionnaire will be about £965. A deposit of £48 is required to qualify any tender. The adjudication will take place at 11 a.m. on Dec. 26, at the Casa Consistorial, Valladolid.

South London Electric Supply Corporation.—The Directors invite tenders for the construction, supply, and erection at their works at Bengeworth-road, Loughborough Junction, S.E., of one 750-kw. steam alternator with pipe connections and sundry ironwork. Sealed tenders must be forwarded to the secretary of the company, Mr. H. H. Boyer, Bengeworth-road, Loughborough Junction, S.E., before noon on Jan. 16. See advertisement.

Perth (Australia).—Tenders are invited by the Duputy-Postmaster-General for the supply of the following telephone material; 19½ miles 26-pair lead-covered cable, dry core, to standard specification No. 7; 5,000 paper sleeves, 3in. long by $\frac{1}{16}$in. diameter; 350 yards paper strips, 2in. wide. Conditions, etc., may be obtained at the General Post Offices at Perth, Adelaide, Melbourne, Sydney, Brisbane, and Hobart. Tenders by Dec. 28.

Shanghai.—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

Bromsgrove (Worcs.).—The Visiting Committee invite tenders for the supply and erection at their new lunatic asylum of the following plant: (Section A) engines, dynamos, booster, and steam services; (B) storage battery and accessories; (C) main switchboard, ring main, feeders, distribution boards, wiring, lamps, and accessories. Specification, etc., may be obtained from Mr. Robert J. Oliver, clerk of the Visiting Committee, Shirehall, Worcester, on payment of £5 for each section of the work as above, which will be returned on receipt of a bona fide tender.

London, W.—The Great Western Railway Company invite tenders for the supply and delivery of the following material required in connection with the electrical equipment of the Hammersmith and City Railway, etc.: (Specification No. 8) steel conductor rails, cast-iron and steel ramps and fastenings; (9) porcelain insulating supports and their fastenings for conductor rails; (10) copper bonds, insulated cable connections, cable terminals, bonding presses, and accessories for connecting up conductor rails. Tenders, addressed to the Secretary, Great Western Railway, Paddington Station, W., will be received on or before Jan. 3.

Madrid.—Tenders are invited for the public lighting by means of electricity of the town of Villanueva y Geltru for a term of 10 years. Twenty-four arc lamps of 500 c.p. and 239 incandescent lamps of 20 c.p. will be required. The concessionnaire will be allowed to supply private individuals without payment of a municipal tax subject to his supplying, free of charge, the Casa Consistorial with 75 kw. per month. He will be required to maintain a duplicate set of machinery in order to avoid the possibility of the town being left in darkness through a breakdown. The annual payment (upset price) to the concessionnaire will be 23 145 pesetas (about £678). The adjudication will take place on Dec. 24. A deposit of £68 is required to qualify any tender.

Porto (Portugal).—The Town Council opens a competition, which will close on March 15, at 3 p.m. precisely, for the concession of the exclusive right of the working of tramways for collective transports of passengers, luggage, and goods in all the municipal public ways, present and future, which favour that service, or in a special way within the limits of the town of Porto, according to the conditions approved in the meeting of Dec. 1 of the present year. The bases to which the eighth condition refers, the Herman Lourenzo Feuerheerd's request, and the rates, with the minima of the journeys, and the maxima of the prices of the passages, are published to the town hall's office for those who want to examine the conditions of the competition. The conditions of the competition are published to the Portuguese Consulate in London.

Madrid.—The *Gaceta de Madrid* of Nov. 9 publishes a notice inviting tenders for the construction and working for 60 years of an electric tramway between Azcoitia and Zumaya (Province of Guipúzcoa), in accordance with certain conditions set out in the *Gaceta*. An application for this concession has already been received from Don Dionisio Sorseta Garcia, who, at the same rates, will enjoy certain preferential rights over other tenderers. The competition will turn, in the first place, on the reduction of the tariff fixed for the conveyance of passengers, etc.; in the event of equal terms being offered, it will turn on a reduction of the period of concession. Adjudication of tenders will take place before the Director-General of Public Works, Madrid, on Jan. 10. A deposit of 16,297 pesetas (about £475) is required to qualify any tender

RESULTS OF TENDERS.

Yarmouth.—The Town Council have accepted the tender of the Callender Cable Company, at £259. 4s., for cables to carry the current to Gorleston.

Insulating Compound.—Messrs. Watson and Co., 119, Victoria-street, Westminster, London, have again secured the contract for the supply of insulating compound for the National Telephone Company.

Worcestershire.—It is reported that the important order for the electric lighting of the new Birmingham University buildings at Selly Oak has been placed with Lea, Son, and Co., Pengwerne Works, Shrewsbury.

London County Council.—The Fire Brigade Committee have recommended for acceptance the tender of Ward Bros. for wiring and supplying fittings for an electric light installation at the new Isle of Dogs station for £140.

Mansfield and District Light Railways.—Messrs. J. G. White and Co., 22A, College-hill, Cannon-street, London, E.C., have secured the contract for the above, Messrs. Bramwell and Harris being the consulting engineers. The value of this contract is £48,000.

Llandudno.—The Urban District Council have accepted the tender of the Hart Accumulator Company, Marshgate-lane, Stratford, London, E., for replacing the storage battery at their electricity works with 256 standard lighting-type cells having a capacity of 450 ampere-hours.

Admiralty Contract.—The Lancashire Dynamo and Motor Company have received an order from the Admiralty for the whole of the electrical equipment for Malta Dockyard, including boilers, engines, dynamos, motor-generators, and motors, in accordance with the specification of Messrs. Preece and Cardew.

Sunderland.—The Corporation have accepted the tender of the General Electric Company, Witton, Birmingham, for the supply of two 300-kw. three-phase generators, 5,500 volts, to be coupled to existing Belliss engines, and two 300-kw. synchronous three-phase motors, 5,000 volts, to be coupled to existing multipolar Silvertown dynamos.

Monte Video Tramways.—This contract, obtained by J. G. White and Co., 22A, College-hill, Cannon-street, London, E.C., as noted in our last issue, consists of 51 miles of permanent way with the accompanying overhead construction. There are 100 cars. The power station will contain generating sets to the extent of 2,000 kw. The value of this contract exceeds £400,000.

Wandsworth.—The Borough Council have received the following tenders for the installation of electric lighting at the Council House:

W. H. McKone and Co. (accepted)	£281	14	0
J. Wilson	295	0	0
Lee and Warran	303	10	0
G. Candler and Sons	313	0	0
E. Probert and Co.	315	15	0
Bromley and Batstone	323	12	6

Davidson Bros.	540	0	0
F. Hayes	550	0	0

Huddersfield.—The passenger receipts for November were £5,018, or £241 more than in November, 1903. An agreement has been entered into with Messrs. J. H. Sykes and Co., woollen cloth manufacturers, Gosport Mills, Outlane, to convey coal to their mill from the Hillhouse railway sidings at 1s. 9d. per ton, the Corporation to extend the line at Outlane, and the firm to lay the line from the extension into their premises, and to make the agreement for seven years.

Digitized by Google

BUSINESS NOTES.

TRACTION.

Dover.—The Corporation are hastening the preliminary steps in connection with the tramways extensions.

Bury.—The Bill providing for, *inter alia*, the extension of the tramways has been approved by the Corporation.

Taunton.—The Corporation have decided to call upon the company to repair the track, which is stated to be in a deplorable condition.

Rhondda.—The Urban District Council have deposited their Bill by which they seek, *inter alia*, an extension of time for the construction of tramways.

British Electric Traction Co.—The directors have declared an interim on the ordinary shares at the rate of 6 per cent. per annum for the half-year to Sept. 30.

Geneva Tramways Co.—The traffic receipts for the month of November amounted to £6,734. 7s., being an increase of £578. 16s. over the coresponding period of last year.

Poole.—At the meeting of the Corporation a memorial was presented asking for the construction of a line from the existing system of the Bournemouth Corporation to Sandbanks and the district.

Sheffield.—The wages of the tramcar conductors, which are slightly lower than those paid in other cities of the same size, are to be increased. This involves an increased cost per annum of £1,306. 10s.

South Shields.—The Town Council have decided that the work of laying the tramlines shall be commenced at the earliest possible date. Contracts for carrying out the work are to be advertised. The Council have decided to erect a commodious car-shed.

New York Underground.—It is reported that, in consequence of the success of the new system, application will be made for a charter authorising an additional line, so as to provide a link between the east and west sides of the city and to complete the circle.

Salford.—Another 1½ miles of tramways have been added to the Corporation system by the opening of the route from the junction of Leicester-road and Bury Old-road to Heaton Park Station. The track is now being laid for a further extension of the route to St. Margaret's Church.

Dunfermline.—The tramway company have completed a survey of the routes over which they proposed to construct lines, and a conference with the District Committee is to be held early in the new year to arrange details previous to the application for sanction to the scheme.

Wellingborough.—This and the Raunds Council have received a communication from the British Electric Traction Company in regard to the company's revised tramway schemes for the district, and also concerning a large lighting project. The matter is under the consideration of the councils.

Spain.—The Public Works Department has received applications for concessions for the following proposed electric tramways: (1) for the town of Vigo, D. Alvaro Lopez Mora; (2) for Madrid, Madrid Electric Traction Company; (3) for Madrid, Soc. Colonia Sanatorio de la Playa de la Malvarossa; (4) for Cadiz, D. Ubaldo Fuester Birlayn.

Dundee.—The financial position for the first half of the current year has turned out to be very satisfactory. The estimated expenditure for the six months was £13,550, while the actual outlay amounted to £120 less. With regard to the revenue, the estimate for the same period was £22,083. 10s., and the actual income was £23,165. 4s., or £1,081. 14s. better than was anticipated.

Southampton.—A motion was extensively discussed at last week's meeting of the Corporation for the appointment of a general manager of the tramways. Finally, the following amendment was carried: "It having been stated that the Tramways Committee will bring up a report as to the appointment of a manager, the consideration of the matter be postponed to the next Council meeting."

Chesterfield.—On Tuesday Major Pringle, on behalf of the Board of Trade, inspected the new electric tramway system constructed for the Chesterfield Corporation by the British Insulated and Helsby Cables, Limited, at a cost approaching £60,000. The inspector was accompanied by Mr. A. P. Trotter, the electrical adviser to the Board of Trade. The inspection was satisfactory, and the cars commenced to run on the Brampton line in the afternoon.

The Paris Metropolitan Railway.—The Eighth Correctional Tribunal has delivered judgment in the case of the disaster which occurred at the Couronnes Station of the Paris Metropolitan Railway in August, 1903. The guard of the train and the stationmaster were each sentenced to a month's imprisonment under the First Offenders Act, with 2,000fr. damages, while the motorman was ordered to pay a fine of 3,000fr., and another guard one of 2,000fr. The railway company is declared to be liable with regard to the claims arising out of the case.

Hindley.—The Council have confirmed a resolution that the Council grant a lease of the Market-street and Wigan-road length of tramways to the South Lancashire Tramways Company on the terms contained in the agreement scheduled to the South Lancashire Tramways Act, 1903, permission to be granted to the South Lancashire Tramway Company to sub-lease the Wigan-road length to the Wigan Corporation on such terms as the Hindley Council approve of, and subject to all statutory and other obligations and agreements existing between the Hindley Urban District Council and the South Lancashire Tramways Company.

North London Electric Tramways.—Sir Colin Monorieff sat in the Westminster Guildhall as arbitrator for the purpose of determining a claim brought by the Hornsey Borough Council against the Middlesex County Council for the recovery of a sum of £2,000. It was stated that in connection with the construction of the electric tramways in North London the County Council required the Borough Council to carry out certain alterations to a number of manholes to sewers. The plan proposed by the County Council was regarded by the Borough Council as a dangerous one, both to the sewermen and the traffic generally, and accordingly the Borough Council carried out the work itself, and now sought repayment of the cost from the Council. After hearing expert evidence the arbitrator reserved his award.

North-Eastern Railway.—A report was brought up before the Tynemouth Council recommending that strong representations should be made to Sir George Gibb and each director of the North-Eastern Railway Company as to the state of things at present existing on the electric system being a source of great danger to the travelling public; that the carriage accommodation was totally inadequate to the needs of the district; and that the withdrawal of the first-class carriages on stopping trains was causing great inconvenience and annoyance to manufacturers and residents of the borough, who had for many years travelled first-class, and that, if steps were not taken to remedy these matters, the Council would be compelled to appeal to the Railway Commissioners and the Board of Trade. The report was adopted and a deputation appointed.

Glasgow.—The Parliamentary Bills Committee of the District Committee of Upper Renfrewshire have been considering the orders of the Glasgow Corporation and the Paisley District Tramway Company to make extensions of their tramway systems in the district. The Glasgow Corporation propose to lay a line from Thornliebank to Barrhead, a distance of three miles, while the latter authority seeks power to lay lines from Glenfield-road, Paisley, to Barrhead, a distance of two miles, and from the boundary of the burgh of Johnstone to Kilbarchan, a distance of one mile. Provision is made for the lines being single, with passing places. The Parliamentary Bills Committee have decided to insist that the lines be double throughout, and they also recommend the District Committee to oppose the orders, so that opportunity may be given for discussing the objections.

Brighton.—The Corporation have adopted the minutes of the Tramways Committee, which read as follows: "A letter was read from the clerk to the Steyning (East) Rural Council with reference to the setting back of the footpath in a portion of Dyke-road, stating that his Council would agree to specified terms. One of these stipulations was to the effect that the Corporation were not to be called on to carry out the work for two years. These terms were approved. The tramways manager was authorised in future to take off any cars that he considered were unnecessary, but requested to report at the following meeting of the committee as to any cars that he may have so taken off. The committee further recommended that the service on the North-road route be altered from an eight minutes' service to a five minutes' service, and that the matter be considered in a month's time."

Rushden.—At the meeting of the Council it was reported that a communication had been received from the British Electric Traction Company stating that they were applying for parliamentary powers to extend the tramways to Stanwick and Raunds, but to give up the line to Irthlingborough, and part of the projected line in Rushden. They were also applying for power to supply electricity in bulk, and were working in conjunction with the Northants Electric Supply Company. They asked the Council to support their scheme. Several members were of opinion that they should oppose the tramway company's scheme for supplying electricity unless they carried out the whole of the scheme previously approved of by the Council. Mr. Ballard said that if either party got a provisional order, it would put the Council out of court as an authority. Ultimately it was decided that the company's scheme in its present form should be opposed, but that if the whole scheme was carried out the Council might be disposed to favourably consider the question of electric supply.

Walsall.—The following particulars refer to the working of the tramways during the past two months: Four weeks ending Oct. 27, 1904—number of passengers, 341,180; receipts, £1,892. 14s.; car miles run, 46,650; receipts per car mile run, 9·73d. Five weeks ending Dec. 3, 1904—number of passengers, 400,754; receipts, £2,215. 4s. 6d.; car miles run, 57,558; receipts per car mile run, 9·23d. Wages paid (including repair of permanent way)—for four weeks ending Oct. 27, 1904, £629. 1s. 11d.; for five weeks ending Dec. 1, 1904, £771. 13s. 7d. The committee have approved the suggestions contained in the manager's report for effecting a saving of mileage in the running of the early morning cars on the Bloxwich, Pleck, and Birmingham-road routes. The Board of Trade have been asked to renew for an indefinite period their order sanctioning the use of electrical power on the lines purchased from the South Staffordshire Tramways Company, which order expires on Feb. 9, 1905. Mr. A. P. Trotter, electrical adviser to the Board of Trade, has inspected the overhead equipment.

Belfast.—We have already noted the contract awarded to Messrs. J. G. White and Co. This is divided into five sections, and supplies some interesting particulars as to the form of construction. Section 1—permanent way: 28½ miles double track, two miles single track, and six miles of double track, repairing and bonding only; the rails are British standard Nos. 4 and 40; the concrete bed is 7in. thick; the special work amounts to £25,000; the paving is granite setts. Section 2—37 miles overhead construction, mostly span wire; the trolley wire is 4/0 S.W.G. Section 3—cables, comprising feeders, telephone and test cables for the above, the cables to be laid on the solid system in earthenware troughs, filled in with bitumen; the dielectric is vulcanised bitumen. Section 4—comprises engines, dynamos, switchboard three-phase condensing plant, etc.; there are three steam dynamos, direct-current, of 1,000 kw. each, at 180 revolutions per minute; there are two 250-kw. three-phase motor-generators, two 125-kw. three-phase motor-generators; there is also a 25-ton crane. Section 5—boiler-house, containing superheaters

Digitized by Google

mechanical stokers, condensers, coal and ash conveying plant, and the usual piping; there are four boilers, working at a pressure of 170lb.

Watford.—At the meeting of the Urban District Council the following recommendations were submitted in regard to the route of the suggested tramways: (1) from the termination of the Bushey light railway opposite Hayden-road to the junction of St. Albans-road with the High-street; (2) from the High-street, running down Queen-street and terminating at St. Albans-road; (3) from the High-street at its junction with Market-street, running along Market-street to Cassio-road, turning up Cassio-road in a north-westerly direction to Whippendell-road, and terminating at the junction of the new Whippendell-road extension with Rickmansworth main road; (4) from High-street at its junction with St. Albans-road, running the whole length of St. Albans-road within the urban district, and terminating at the boundary of Bushey Mill-lane. The committee also recommended that certain street widenings should be carried out, and that the tramway be paved with jarrah wood block paving throughout the entire route. After some discussion the report was adopted, with the following variations: that the portion of the proposed tramway from the junction of Market-place with Market-street to the junction of St Albans-road with Langley-road be omitted or deferred; that if this section was subsequently carried out specified street widenings should be effected; and that the rails should be laid in the most approved method in order to secure silence.

Greenock.—The following minute from the Electricity Committee was passed at the meeting of the Corporation: "The sub-committee on tramways reported that they had met on Oct. 14 and had considered a further letter from the tramway company, in which the company stated that, while they were prepared to increase their guaranteed annual consumption, they were not prepared to admit that there was any provision in the lease for such increase being paid for at the maximum rate of 1½d. per unit. The company further expressed the desire to meet the engineer in order to discuss the matter with a view to arriving at a settlement. It was agreed to authorise the engineer to meet the directors of the company for this purpose, and report to a future meeting. The engineer now stated that, as authorised, he had met the directors of the company in London and discussed the question of maximum demand in connection with the supply of energy to the tramways. As a result of the negotiations, the company, while not admitting they were liable to pay at an increased rate for the additional guaranteed consumption, were prepared to temporarily increase their guarantee from 500,000 to 600,000 units per annum, and to pay for the additional 100,000 at 1½d. per unit, this arrangement to take effect as from Aug. 1 last, and to remain in force until the next term for the revision of rates. The company have confirmed this offer.

London County Council.—The agenda for Tuesday's meeting of the Council contained an adjourned report of the Finance Committee with reference to capital votes of £21,500, £104,000, £154 000 £26,100, and £14 400 for street improvements in connection with tramways. The report of Mr. J. Allen Baker, chairman of the Highways Committee, upon the New York Rapid Transit Subway is to be printed. The Highways Committee ask that expenditure on capital account not exceeding £3,250 be sanctioned in connection with the construction of a temporary end screen for the first portion of the Greenwich generating station. The committee also recommend that advertisements be allowed on the top facia panels, in addition to the ordinary spaces, on the top covered cars. They also recommend that technical assistants employed temporarily in the tramways department be paid at rates not exceeding £5 a week. The committee further recommend that plans be prepared for the line between the Archway Tavern and the county boundary at Highgate Archway on the overhead principle, so that they may be submitted for the approval of the Board of Trade without delay. Pending the reconstruction of the Council's northern system this line will probably be worked by the Middlesex County Council in connection with their system of light railways. The receipts from April 1 to the 10th inst totalled £464,619, against £363,732 last year. The Chairman of the Highways Committee stated that the committee were now endeavouring to get the Commissioner of Police to approve a lower built car with a covered top, so that they could be used on the Tooting lines. Mr. John Burns, M.P., asked the chairman if the committee would consider the question of proposing to the railway companies the reconstruction of the Clapham and Tooting railway bridges, so that the cars could pass underneath, the Council and the companies bearing the cost between them. The Chairman said the question was one which the Highways Committee would be glad to consider. The petition presented to the City Corporation by Alderman Sir John Bell against tramways along the Embankment was referred to committee. A resolution was read from the precinct of St. Ann, Blackfriars, approving of the proposal of the County Council provided that the suggestion for widening the north-western corner of Blackfriars Bridge was carried out. This communication was also referred to the Streets Committee. Mr. Fortescue's motion, of which we have already given particulars, was adopted after considerable discussion. Finally, the Streets Committee presented a report on a conference which had taken place between its members and the representatives of the Highways Committee of the County Council. It was stated that the consideration of the matter had been adjourned until the first meeting in the New Year in the hope that by that time the report of the Royal Commission on London Traffic would be in the hands of the Corporation.

The Metropolitan Railway.—Heads of an agreement have been arranged between this company and the Great Central Company, and will be scheduled to their joint Bill for next session. The following are the chief features: The Metropolitan Company to grant a lease for 999 years of the line from Canfield-place to Harrow South Junction at an annual rental of £22,000. The Metropolitan Company to have running powers between Harrow South Junction and a junction to be provided by the Great Central Company at a point north of the Great Central Company's proposed new junction with their Northolt line for passenger goods and mineral trains at mileage rates with an allowance of 33⅓ per cent. for running expenses, with the usual facilities for dealing with empty stock. The present station at Willesden Green to be enlarged at joint expense of the two companies, and exchange platforms constructed. The Great Central Company not to convey traffic locally to or from any point between Marylebone and Harrow South Junction. The Metropolitan Company to have a through crossing at Wembley Park, providing for access to their yard and property on the south-west side of the line as at present. The Metropolitan Company to lease their railway from Harrow South Junction to Verney Junction with the Chesham branch, including stations, works, sidings, wharves, approaches, lands, and conveniences, except properties to which the Surplus Lands Committee have a beneficial interest, to a Metropolitan and Great Central Joint Committee for 999 years at a yearly rental of £44,000, and the Joint Committee shall assume the interest and obligations of the Metropolitan in respect of the Brill Tramway; but if and when the same shall become vested in the two companies that portion of it lying to the west of the Princes Risborough and Grendon Underwood line of the Great Central Company shall, if the Great Central so request, be transferred to such parties as they may indicate at a price fairly proportionate to the cost of the whole. The Great Central Company to put upon the joint line a minimum amount of through traffic of £45,500 a year gross. Any deficiency during the first two years in any one of such years to be made up in the next following year. The joint lines to be managed by the Metropolitan Company's officers for the first five years under the direction of the Joint Committee, and subsequently in periods of five years alternately by each company unless otherwise agreed. Each company to be allowed 33⅓ per cent. of the mileage receipts in their own trains for running expenses. Accounts to be made up half-yearly—June and December. Any deficiency arising on the working of the joint lines to be borne in equal proportion by the two companies, and any profit up to and including £5,500 per annum to be received by the Metropolitan Company, and the balance of profit thereafter to be divided equally between the two companies. If in any year the Metropolitan Company's mileage proportion of receipts between Baker-street and Harrow South Junction accruing from passenger train traffic to and from Baker-street and the stations on the Inner Circle Railway, with the joint-line stations north of and inclusive of Harrow, fall below the ascertained receipts for the year 1904 (after allowing for any reduction of rates and fares, if the future receipts are thereby reduced below the 1904 figures), by reason of the diversion of any of such traffic to or from Marylebone, the Great Central Company to pay the Metropolitan Company 66⅔ per cent. of the mileage proportion accruing to the railway between Marylebone and Harrow South Junction in respect of such diverted traffic up to the amount of such ascertained receipts. When the traffic referred to in the last paragraph exceeds the 1904 figures, the balance, after deducting running expenses at 33⅓ per cent. to each company, to be divided half-yearly for the first five years in the proportion three-fifths to Metropolitan and two-fifths to Great Central, and thereafter in equal proportions. The fares and rates from Marylebone to Harrow and stations north thereof on the joint line not to be less than those charged from Baker-street (Metropolitan). The out-of-pocket cost of the Metropolitan Company in connection with the arbitration proceedings to be paid by the Great Central Company. This agreement to come into operation upon the opening of the Great Central and Great Western joint lines for passenger traffic through (*via* Northolt) to Marylebone.

LIGHTING AND GENERAL.

Maidstone.—The Electricity and Light Railways Committee have re-elected Councillor Vaughan chairman.

Ormskirk.—The Guardians have decided that a loan of £4,000 be obtained for the electric light installation.

"Engineering Diary."—We refer to a notice relating to free copies of this periodical appearing in another column.

Eccles.—On Sunday the organ at the parish church was driven for the first time by electricity supplied from the Council's cables.

Dorking.—The last report of the Finance Committee shows that o the £20,000 borrowed for the electric lighting undertaking, £19,705 has already been expended.

Electricity Exhibition.—Particulars of the electrical exhibition to be held at the Queen's-road Baths, Bayswater, from March 27 to April 8, 1905, appear in another column.

Oldham.—An enquiry was held on Wednesday into an application of the Town Council for sanction to borrow £48,114 required for the electricity undertaking. Attention being called to an item of £565, the cost of photographs, souvenirs, etc., the enquiry was adjourned indefinitely in order that details might be obtained.

Edmonton.—The District Council met specially for the third time on Friday last to consider the offers of the North Metropolitan Electric Power Supply Company, Foote and Milne, Limited, National Electric Construction Company, and the Electrical Engineering Company. A motion was before the Council when it adjourned on the last occasion that the offer of the North Metropolitan Company should be accepted, to which an amendment had been proposed that the Council should themselves take steps to supply the compulsory area. After further discussion the amendment was defeated. A further amendment was then proposed that the Council should agree to lease its powers to the North Metropolitan Company, subject to terms to be agreed upon by the Council. It was stated that the company had previously offered better terms than it now proposed, and it was with the object of getting a more favourable offer that the amendment was moved. This amendment was then adopted.

Digitized by Google

Grimsby.—Sanction has been received to borrow £3,000 for the extension of mains and the purchase of meters in connection with the electricity works for the next 12 months.

Newmarket.—The question of further alterations in the Grainger market will come early in January before a special meeting, which will also consider the introduction of electric or other lighting.

Luton.—The financial position of the town's electricity undertaking was discussed at the last meeting of the Town Council. A resolution to establish a depreciation fund was, after discussion, defeated.

Woolwich.—The Borough Council have resolved to apply to the London County Council for permission to borrow two sums of £7,500 each for the extension of electricity mains to Eltham and Shooter's Hill.

Penny-in-the-Slot Meters.—Penny-in-the-slot meters for electric light have been distributed by the Birkenhead Corporation Electricity Committee, and about 25 houses and small shops have them now in active working.

Leeds Hospitals.—The Corporation Hospitals' Committee have decided to accept the tender of the Magneta Company, of Winchester House, London, for the supply of their electric time system to the Seacroft Hospital.

Port Glasgow.—The Town Council are considering a scheme and report by Messrs. D. and A. Home Morton, consulting engineers, Glasgow, for the electric lighting of the burgh, in conjunction with the destructor plant already installed.

Rushden.—The Urban District Council are considering a communication from Messrs. Leadbitter and Harvey, of Newcastle-on-Tyne, to an application by Mr. Harvey, of Richmond, for consent to a provisional order for the supply of electricity in Rushden, Higham, and Irthlingborough.

London County Council.—On Tuesday it was agreed to lend the St. Pancras Borough Council £7,515 for electric light installation. The Council have decided to allow the Woolwich Borough Council eight years for the repayment of their £1,000 loan for wiring consumers' premises for electric lighting.

Carmarthen.—Under the joint Bill of the South Wales Electrical Power Distribution Company and the Carmarthenshire Electric Power Company, power is sought to transfer and vest in the South Wales Electrical Power Distribution Company the undertaking of the Carmarthenshire Electric Power Company, and for other purposes.

Hipperholme.—The Rural District Council have sealed the memorial for an electric lighting provisional order, and have decided that in case the Board of Trade gave leave to restrict the compulsory area to a smaller district than that originally advertised, the seal of the Council be affixed to a memorial for similar powers in such restricted area.

St. Albans.—The Rural District Council have consented to the application of the St. Albans and District Electric Supply Company for an electric lighting provisional order in respect to the rural district of St. Albans. It appears that the city authorities have granted the company powers, but they cannot get a site within the city; consequently, must go outside.

Southern Indian Railway.—During the past year, says *Indian Engineering*, the station buildings and yards at Tanjore and Trichinopoly Stations on the South Indian Railway, as well as the general offices at Trichinopoly Junction, have been provided with electric lights, and the public rooms at both stations, as well as the rooms of the officers in the general offices, have been provided with electric fans in lieu of punkahs.

Watford.—The number of electric light consumers connected to date is 370. The Windsor-road sub-station has now been put into service. The building of the Market-street and Wiggenhall-road sub-stations has been completed. A new type of arc lamp is being fixed to the three columns in the Market-place and at the public library at an estimated cost of £25. The engineer in his last report stated that since the first arc lamp had been erected at Messrs. Ward, Jones, and Co., eight weeks ago, 11 other arc lamps had been fixed in the town.

London Gazette.—A receiving order has been made out on creditors' petition in the estate of Edward Sumner, electrical engineer, 140, Dale-street, Liverpool. Frederick Seymour Salaman, 1, Oxford-court, Cannon-street, E.C., has been appointed trustee in the estate of William Henry Lloyd Watson and George Huntingdon, electricians, 83, Battersea-rise, London. Henry Edward Abbott, 5, Fenwick-street, Liverpool, has been released as liquidator in the estate of the Electrical Regulating and Lighting Syndicate, Limited, Liverpool.

Ebbw Vale.—At the Council meeting on Tuesday, the draft agreement was submitted between the Council and the Ebbw Vale Company with reference to a supply of electricity for lighting purposes, which had been approved by Mr. Wilson, electrical engineer to the Council. The various clauses were approved, with the exception of one providing that the delivery of energy should be given at one spot instead of three, as desired. It was decided to negotiate for the amendment of the agreement to the effect that delivery be arranged for at three centres.

Montrose.—The directors of the North of Scotland Electric Light and Power Company, Limited, last week threw their works open for inspection. The following few figures are available, showing the progress made by the undertaking: July, 1901, supply commenced; December, 1901, 2,000 equivalent 8-c.p. lamps connected; December, 1902, 6,422 equivalent 8-c.p. lamps connected; December, 1903, 11,670 equivalent 8-c.p. lamps connected; Nov. 30, 1904, 14,880 equivalent 8-c.p. lamps connected. These figures include motors to the extent of over 150 h.p.

Gravesend.—Councillor Enfield has been appointed chairman of the Electric Committee for the ensuing year. Mains are to be laid at a cost of £165 to supply Messrs. Russell's Brewery, Limited, with current to work certain fans they propose installing. The electrical engineer, in a recent report, states that in a local case in which a nuisance was alleged to exist by reason of noise from machinery, it had been satisfactorily established that as far as the electric motors were concerned there was no cause for complaint, such motors being entirely free from both noise and vibration.

Bexhill.—The electrical engineer has been authorised to arrange an electrical exhibition in the borough, and a sub-committee, consisting of the chairman, Alderman Young, and Councillors Longman and Paton, formed to supervise and report upon the necessary arrangements. The committee's last report stated that they had received four applications for the supply of electricity since the previous meeting, representing a total of 124 8-c.p. lamps. The total number of lamps connected to Dec. 12 was stated to be 23 572, and the total number of consumers connected to the same date 476.

Battersea.—At the last meeting of the Borough Council, the Lighting Committee stated that the electrical engineer had reported that the model prepayment electricity meter submitted by the British Thomson-Houston Company, Limited, as per their offer reported to the Council in October, had been thoroughly tested, and had proved to be satisfactory. Arrangements were consequently being made for the whole of the meters on the Latchmere Estate to be replaced with meters as per model meter, and for the supply of the necessary meters required both for the town hall and Latchmere estates.

Electrical Testing.—The Westminster Electrical Testing Laboratory are now, we are informed, carrying out a complete series of tests on 12 of the principal makes of incandescent lamps. The lamps have been purchased in the open market, and they are being run for 800 hours, and are being tested for candle-power and current consumption at start, and after 100, 200, 400, 600, and 800 hours' running. All lamps are being run together on the same circuit, and are being tested against the same standards. The test, therefore, will be perfectly fair. The results of the measurements obtained will be fully tabulated and averages will be worked out.

Aberdeen Telephones.—At the last joint meeting of the Finance and Streets and Roads Committees of the Town Council the terms of the draft agreement with the National Telephone Company were considered. It deals with the improvement of the telephone service in the city, part of the scheme being the laying of underground wires. The meeting, after a long discussion, agreed to practically accept terms similar to those contained in the agreement between the Edinburgh Corporation and the National Telephone Company. The National Telephone Company, it is reported, are prepared to spend £50,000 upon improving the service in the city.

Walsall.—Mr. Alderman William Brownhill has been appointed chairman and Mr. Alderman Noake vice-chairman of the Electricity Committee for the ensuing year. The total number of consumers supplied on Nov. 30 last was 380. During the past month the total units generated at the station was 156,417. The total output from the main generators was 151,417 units. The total units from the transformers was 119,472 (estimated). The total units registered on the meters was 111,403. The machinery was run for 684 hours. The wages paid amounted £133. The question of extending the electric mains in Lyswys-street and Mellish-road is under consideration.

Bermondsey.—The terms of the agreement proposed to be entered into between the Council and the Surrey Commercial Dock Company for the supply of electric power and lighting have been settled by the Council as follows: for power, 2d. per unit up to 10,000 units, 1½d. per unit for each unit in excess of 10,000 up to 20,000, 1½d. per unit for each unit in excess of 20,000 up to 50,000, and beyond 50,000 a charge of 1½d. per unit be effected; that for lighting, 3½d. per unit be charged up to 30,000 units, any excess to be charged at 2d. per unit. There is to be a condition that a minimum of 30,000 units be used for both power and lighting, and that the agreement be made for not less than three years.

Hampstead.—At the last meeting of the Borough Council the General Purposes Committee reported that they had had before them a letter, dated Dec. 1, from the Electric Power Development Company, Limited, of Connaught-mansions, Victoria-street, enclosing a notice inserted in the *London Gazette* of their intention to apply to Parliament during the ensuing session for power to supply electric energy in bulk in the London district; and they recommended that the application of the Electric Power Development Company, Limited, and any other applications of a like nature by other bodies or persons, be referred to this committee, with power to consult with the Lighting Committee and with other local authorities interested; and that they be authorised to take such steps as may be necessary to oppose the Bill or Bills before Parliament. The report was adopted.

Willesden.—In his report for the year ended March 31, 1904, the engineer and surveyor, Mr. O. Claude Robson, M.I.C.E., says: "An important alteration in the public lighting of the district has been effected since my last report, by the installation of electric light and the substitution of 140 electric arc lamps for the gas lamps in some of the principal thoroughfares. A number of the arc lamps are kept burning until midnight; two 32-c.p. incandescent lights on brackets being used on others for the remainder of the night. The cost for each of these lights is £25. 10s. and £19 per annum respectively. Six incandescent electric lights in Willesden-lane and Salusbury-road are also fixed by the electricity department for experimental purposes. The removal of gas lamp columns, as mainly necessitated by the fixing of electric light standards, has involved an outlay of £130. 14s. 8d., representing the shifting of 289 lamps. A large number of these have been removed to store, and will be utilised where new lamps are required. The contracts for the erection of the main electricity works in Taylors-lane, and the sub-station in Salusbury-road, have been finally settled, the ultimate cost of each of these works having been as follows—viz.: Main generating station, Taylors-lane—building, £23,869. 15s. 8d.; entrance gates and walls to Selwyn-avenue, £93.

Digitized by Google

9s. 1d.; sidings, £1,534. 5s. 6d.; coal bunkers, £313. 3s. 7d.; cooling tanks, £846. 2s. 8d.; erection of machinery, £167. 14s. 8d.; lighting, £331. 16s.; telephones, £24. 6s. 6d.; various items certified by electrical engineer, £246. 0s. 4d.; sundries, £22?. 7s. 5d.; chimney shaft, main station, £5,614. 16s. 11d.—total, £33 768. 18s. 4d. Sub-station, Salusbury-road—building, £10,452. 14s. 2d.; lighting, £286. 5s. 4d.; telephones, £19. 19s. 8d.; tiling, £96. 4s. 10d; heating, £40. 18s. 6d.; entrance gates, £74. 8s. 6d.; sprinkler fire-extinguishing apparatus, £129. 0s. 8d.; various items certified by electrical engineer, £28. 18s. 3d.; sundries, £377. 2s. 5d.—total, £11,505. 12s. 4d. Total of both stations, £45,274. 10s. 8d. This shows a saving of £6.830 upon my estimate for these works as submitted in September, 1901. A reduction of £1,323 has also been made upon the tenders received, which amounted to £46,597. The main station in Taylors-lane was sold to the North Metropolitan Electric Power Supply Company by agreement with the Council, the sub-station and offices only in Salusbury-road now being retained by the Council."

Kensington.—The Council have consented to applications of the Kensington and Knightsbridge Electric Lighting Company, Limited, to erect a Bastian mercury vapour lamp in Kensington Court. The company will fix the lamp, and provide a meter at their own cost for the purpose of measuring the current taken, and they undertake to charge the Council for the lighting at the present rate paid for gas and renewals. A proposal of the Gaslight and Coke Company to substitute high-pressure incandescent gas lighting for the present electric arc lamps in Kensington High-street and Kensington-road has been declined as far as that road is concerned. The Council have been in communication with the Postmaster-General, calling his attention to the objection entertained by the Council to the laying of underground telegraphic lines across streets, and have received a reply pointing out that it is no part of his policy to connect single houses on one side of the street by laying underground lines from the main cables on the other side of the street, and that whilst in a few isolated cases it has been found to be more convenient and economical to tap the cables in the middle of a street rather than at one end of it, it does not necessarily follow that the number of crossings are increased thereby, as the crossing in the middle of the street may obviate the necessity for a crossing at the end; the Postmaster-General, therefore, asks that the Council will now grant consent to crossings in Argyll-road and Sydney-place (applications 400 and 401) which have previously been refused. The committee in their last report report recommend that the Postmaster-General be informed that this Council adhere to the view they have already expressed, that the crossing of streets by underground telegraphic lines should be obviated as far as practicable by the laying of such lines along the sides of the streets, and that they cannot see their way to grant the two applications referred to. Applications received from the Post Office for permission to lay pipes for telephone wires, etc., in accordance with plans submitted, in Ladbroke-grove, Cornwall-gardens, Hanover-terrace, and Kensington-square have been agreed to, as well as a notice from the Brompton and Kensington Electricity Supply Company relative to a proposed extension of their mains, etc., in Cathcart-road. The Kensington and Knightsbridge Electric Lighting Company have also obtained permission to establish a testing station in the town hall building, and to fix the necessary apparatus therein.

PROVISIONAL PATENTS, 1904.

DEC. 12.

27013. An electric automatic stopping device applicable to knitting and other textile fabric machines. Isaac Hardy Parsons and Henry Randall Waddington, 2, Laurel-road, Leicester.

27028. Improvements in flexible continuous covering for ploughway of electric conduit system and apparatus on cars for manipulating the said covering. Thomas Thornton Dewhirst and Benjamin Biggs, 189, High-street, Lewisham, London.

27033. Improvements in electromagnetic releasing mechanism for electric switches and cut-outs. Charles Mark Dorman, Reginal Arthur Smith, and Herbert George Baggs, Ordsal Electrical Works, Salford.

27060. Improvements in controlling devices for electric motors Burnett Clifton Kenyon, 18, Southampton-buildings, Chancery-lane, London.

27082. Improvements in or connected with electrical counting apparatus, more especially applicable for use in connection with ships' logs. Dolland and Co. and Tyson Crawford, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

27083. Improvements in the control of electric motors and in apparatus therefor. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

27084. Improvements in controlling mechanisms for self-propelled vehicles. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

27095. Improvements in electric telephony. Charles Adams Randall, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

27096. An improvement in electrical signalling apparatus particularly applicable to fire-alarms. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Act.-Ges., Germany.) (Complete specification.)

27100. Improvements in and relating to electric motor apparatus. Mavor and Coulson, Limited, and Henry Alexander Mavor, 46, Lincoln's-inn-fields, London.

DEC. 13.

27114. Improvements in and relating to operating gear for moving the points on electric and other tramways. Alfred Charles Virgin, 24, Kingsley-road, Cotham, Bristol. (Complete specification.)

27115. Improvements in reverse current circuit breakers and indicators for alternating currents. Leonard Andrews, 38, Deansgate, Manchester.

27135. Improvements in hangers or ears for overhead electric trolley wires. Henry Heap, James Bailey, Thomas Brierley, Robert Billington, Abraham Richardson, James Haydock, and Thomas Smith Jones, 6, Bank-street, Manchester.

27168. An improvement in the method of automatically regulating the voltage in electric light and power circuits with varying loads. Max James Eccles Tilney, 8, Astwood-road, South Kensington, London.

27185. Improvements relating to electric conductors. Frederick Wilhelm Sorg, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

27199. Improved method of accelerating the excitation of electrical machines. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens Schuckertwerke G. m. b. H., Germany.) (Complete specification.)

27201. Improvements in connection with electrostatic watt-meters and watt-hour meters. Ernest Wilson, 322, High Holborn, London.

27209. An improved system of electrical distribution for railways and method of operating same. Josef Henrik Hallberg, 18, Buckingham-street, Strand, London. (Complete specification.)

27211. Improvements in protection of electric distribution systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

DEC. 14.

27217. Improvements in and relating to telegraphic transmitters and receivers. Joseph Esser, 51, Hohenzollern-ring, Cologne, Germany. (Date applied for under Patents Act, 1901, May 2, 1904, being date of application in Germany.) (Complete specification.)

27246. Improvements in electrical measuring instruments. Siemens Bros. and Co., Limited, and Ernest Akehurst Holmes, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

27260. Improvements in apparatus for electrode deposition. Alfred Jerome Betteridge, 77, Colmore-row, Birmingham.

27285. Improvements in emergency brakes. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

27286. Improvements in emergency valves for fluid pressure systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

27287. Improvements in brakes for hoists and the like. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

27297. Improvements in and relating to means for lighting and extinguishing gas lamps by electricity. Giorgio Giorgi, 4, South-street, Finsbury, London. (Complete specification.)

DEC. 15.

27310. Improvements connected with electric glow lamps. Charles Edmund Abell, 11, Burlington-chambers, New-street, Birmingham.

27317. Improved means of reflection in connection with electric and other lights. Thomas David Jackson, 6, Finkle-street, Stockton-on-Tees.

27343. Improvements in electrical switches. George Eason, 52, Queen Victoria-street, London. (Complete specification.)

27352. Improvements in electric controlling apparatus. Otis Elevator Company, Limited, 55, Chancery-lane, London. (Otis Elevator Company, United States.)

27399. Improvements in electricity meters. William Hamilton and Ferranti Limited, 18, Southampton-buildings, Chancery-lane, London.

27400. Improvements in systems of electric motor control. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

27401. Improvements in electric motor control systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

27402. Improvements in maximum-demand electric indicators. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. The General Electric Company, United States.)

Digitized by Google

27403. Improvements in maximum-current indicating devices. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

27404. Improvements in metal-working machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Jan. 5, 1905.

1903.

27069. Arc lamps. Cotis.

27199. Electric arc lamps. Lewis.

27316. Arrangements for prepayment or automatic supply of electricity. Warden-Stevens.

27330. Electric telephone systems. Fairweather. (Stromberg Carlson Telephone Manufacturing Company.)

27399. Means for separating and supporting accumulator plates. Leitner.

27783. Storage batteries or electrical accumulators. Romanoff (London) Syndicate, Limited. (de Romanoff.)

28063. Telephone transmitters. Fairweather. (Kellog Switchboard and Supply Company.)

28059. Earth indicating apparatus for trolley standards and other parts of electric traction systems. British Thomson-Houston Company, Limited, and Cubitt.

28183. Electrically-actuated musical instruments. Dickson.

1904.

869. Relays for recording, retransmitting, and controlling currents of electricity and apparatus therefor. Johnston.

2930. Electrometers of the induction type. Lewis.

2948. Wattmeters. Duddell.

3216. Fuse box for electric cables. W. T. Henley's Telegraph Works Company, Limited, and Nichols.

3236. Tremblers for electrical circuits. Wilson and Wilson and Pilcher, Limited.

3243. Electric arc lamps. Mensing.

3261. Valves for fluid-pressure brake systems. British Thomson-Houston Company, Limited. (General Electric Company.)

3431. Telephones. Kingsbury. (Western Electric Company.)

3492. Method of fixing the covers to electrical switches and other articles. Tucker.

3547. Electric switches. Kingsland.

3588. Controlling alternating-current motors. British Thomson-Houston Company, Limited. (General Electric Company.)

3589. Alternating-current electric motors. British Thomson-Houston Company, Limited. (General Electric Company.)

3590. Means for controlling electric motors. British Thomson-Houston Company, Limited. (General Electric Company.)

3603. Electric controlling apparatus for electric circuits. Leitner and Lucas.

3643. Electric light baths and the like radiant therapeutic appliances. Scott.

3665. Electric motor controllers. British Thomson-Houston Company, Limited. (General Electric Company.)

6218. Automatic suspension device for the suspension of electric arc lamps and other objects. Imray. (Deutsche Waffen und Munitions Fabriken.)

8657. Printing telegraph receivers. White.

10691. Electrically-operated typewriters and telegraphs. Roussel and King.

19234. Rail joint and electrical rail bond. Webber. (Date applied for under International Convention, Sept. 16, 1903.)

19341. Bearings for motors, dynamos, and other machines. Haynes.

19422. Regulating mechanism for arc lamps. Haddan. (Allgemeine Beleuchtungs und Heizindustrie Act.-Ges.)

NOTES.

New Publication.—The British Electric Transformer Company have this year again sent us an elegantly-bound copy of "Whitaker." There is no need to sing the praises of this hardy annual, the virtues of which are known to everybody.

Bequests to Commerce.—When Benjamin Franklin died in 1790 he bequeathed the sum of £1,000 to be invested and kept intact for a century for the benefit of apprentices in his native city of Boston. By judicious investments this legacy has accumulated into a fund of £54,000, and a large school of industry was founded. Mr. Andrew Carnegie has now presented the same city with a sum of £108,000 for a like purpose.

Wireless Telegraphy.—A good deal has been heard of late of the importance of the North Sea from a naval point of view, and Lieutenant Loring, one of the experts to the Admiralty, has visited the neighbourhood of Fraserburgh with a view to the selection of a site for another wireless telegraphic station. It is reported that the apparatus will not be erected on the coast, as such a situation might leave it unduly exposed to destruction by an enemy, and Lieutenant Loring favours a site at Rathen.

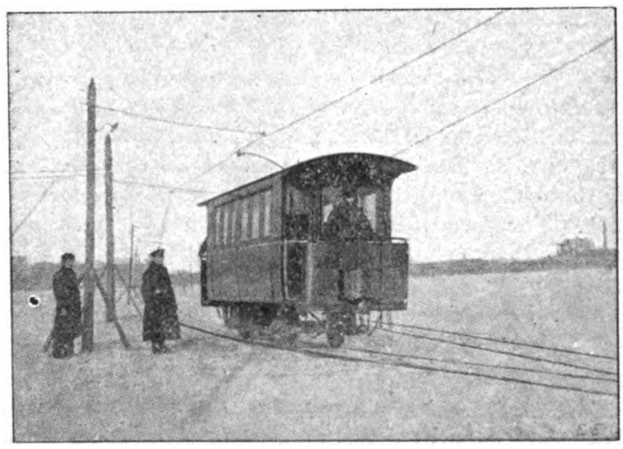
Electricity and Massage.—A reference appears in the *Lancet* to a form of treatment which has been devised by Dr. A. Bobrowa, a Moscow physician, who terms it "auto-conduction." It consists of massage with the simultaneous application of electric currents, the latter being conveyed through the operator's hand, which is the only electrode employed. Faradic or direct galvanic currents are not used in this method, but only high-frequency currents. Dr. Bobrowa has found the treatment useful for a number of maladies, including rheumatism, diabetes, dyspepsia, and neuralgia. This is another instance of the growing favour with which the medical profession regards electro-therapeutics.

Abyssinian Telephones.—Communication by telephone in Abyssinia is making great advances. Already there exists 800 miles of line, and 1,000 miles more have been planned out. A statement issued by the Italian Ministry of Posts, which is entrusted with the work, shows that the undertaking is being conducted in the face of several uncompromising obstacles. In some districts the posts have to be continually re-erected, because, through torrential rains turning the land into soft bog, they have fallen down. In drier districts wooden posts are devoured by insects, and when they are replaced by others of iron they are carried off by the population to be converted into useful implements of husbandry. This necessitates a special police for telephone lines, which have to be constantly patrolled.

Electricity v. Fog.—Prompted by the weather we experienced last week, Sir Oliver Lodge makes an interesting offer in the *Times*. He prefaces his proposal by stating that an electrical method for dissipating fogs is not the right remedy for this artificially-intensified evil, any more than free meals and free doles are a sound remedy for the problem of poverty, yet, like them, it may be useful as a temporary palliative in times of stress and while better methods are being evolved. The cost of applying such a method to a whole city would probably be prohibitory, but there are important centres, says Sir Oliver, where any means of mitigating the nuisance would seem to be legitimate. As a private person cannot conduct experiments in the open streets, and such tests would entail substantial expenditure, Sir Oliver offers to give a private demonstration of some apparatus at Birmingham to a deputation of municipal or other engineers, who could judge how far they could recommend its experimental adoption on a larger scale. Though an installation on a practical scale would mean a large outlay for equipment, operating costs would only be incurred occasionally, and would be small as compared with the expense of artificial illumination on foggy days. The proposed tests may be welcomed as a step towards showing whether the suggestion possesses more than academic interest

Junior Institution of Engineers.—The election is announced of Mr. Philip Watts, F.R.S., director of naval construction, as a vice-president of this institution. On the invitation of the chairman (Mr. Samuel Cutler, jun., M.I.Mech.E), a large number of the members of this institution recently visited the International Gas Exhibition at Earl's Court. They were received by Mr. J. W. Helps, M.I.C.E., chairman of the Advisory Committee of the Institution of Gas Engineers, under the auspices of which the exhibition was held, and shown over by him and Mr. S. Y. Shoubridge, of the South Suburban Gas Company, Mr. A. E. Broadberry, of Tottenham, and Mr. A. W. Onslow, of the Royal Arsenal, Woolwich. On Saturday afternoon, Jan. 7, at 2.30 p.m., a visit will take place to the Voelker Incandescent Mantle Company's factory, Albert Works, South-street, Wandsworth.

A Tramway on Ice.—Our New York contemporary, *Dun's Review*, contains an illustration (which we reproduce) of a remarkable, if not unique, light railway. When the



severe weather sets in at St. Petersburg, and ice sends the ferry-boat into seclusion, a narrow-gauge line with a overhead trolley wire makes its appearance on the crystal track, and conveys numerous passengers across the river at ½d. per journey. Who can say after this that Russia's internal developments are behind the times?

Royal Meteorological Society.—At the meeting of this society last week an interesting discussion took place on Mr. F. J. Brodie's paper "The Decrease of Fog in London during Recent Years," which we noticed in our issue of the 25th ult. A paper by Dr. W. N. Shaw, F.R.S., and Mr. W. H. Dines on "The Study of the Minor Fluctuations of Atmospheric Pressure" was then read. The authors described an apparatus called the "microbarograph," which they have designed to magnify the minor fluctuations, and at the same time to disentangle them from the general barometric surges. They also showed some interesting records from three of these instruments The authors wish to obtain information as to the nature of the disturbances and the causes to which they may be assigned. Among the causes which suggest themselves as likely to produce temporary fluctuations of the barometric curves are stated by the authors to be (1)

Digitized by Google

atmospheric billows passing along surfaces where there is discontinuity of density in a manner somewhat similar to ocean waves; (2) the passage of minute whirls or cyclonic depressions of small scale; (3) variations of pressure due to the attraction or repulsion produced by electric stress, as masses of air at different potential pass over; (4) the mechanical effects of wind; and (5) the mechanical effects of rapid condensation of aqueous vapour. As regards Mr. Brodie's paper, it was curious that it should be read at a time when fog had disorganised the whole traffic of London.

New Zealand.—An installation of electric lighting for Hawera and neighbouring towns was recently completed by the electric lighting company of that town, who engaged Messrs. Steuart and Fenn, of Dunedin, as the engineers. Power is obtained from the Waingorgora River, the fall being approximately 40ft. Owing to the peculiar course of the river, it has been possible to obtain power much more easily and cheaply than is usually the case. Without the necessity of a dam of any kind, the water has been diverted through a tunnel, and thence is led through fluming to the turbines, which are of the horizontal type. When working at full load they are capable of developing 230 h.p. each at a speed of 600 revolutions per minute. The speed is kept constant by means of a Woodward governor. The turbines are each directly coupled to a three-phase alternator, having an output of 65 kw. at a pressure of 5,500 volts, which is the highest pressure yet used in New Zealand. From the switchboard the current is transmitted to the various towns through lines of pure hard-drawn copper wire, supported by poles placed at a distance of about two chains apart. To secure safety from fallen wires iron prongs are placed beneath the wires on each post and connected with the earth wire, so that should a break occur the wire will drop into the prong and the current will be conveyed to earth. Transformers are installed at each of the towns to reduce the voltage. The system has been so designed that the output of energy may be increased to 700 h.p. without interfering with the existing arrangements, except that it will be necessary to dam the river at the power-house.

New York Underground.—As the operation of two tracks carrying local trains at one-minute intervals on the New York Underground is in contemplation, it was necessary to devise an adequate system of signalling. The method decided upon, of which an account appears in the *Street Railway Review*, is a development of the electro-pneumatic switch and signal system used for years on steam railways. In the operation of this system electricity and compressed air have joined forces. The electrical apparatus does not embody anything of decided novelty, but the air compressors are unique in design. They consist of two-stage machines, built by the Ingersoll-Sergeant Drill Company, of New York, with horizontal inter-cooler, fitted with the Ingersoll-Sergeant piston inlet valve and designed throughout for maximum economy, simplicity, and reliability. Nine compressor units have been installed, and three more are under construction. Each compressor is connected by a Morse silent chain to a 35-h.p. Westinghouse direct-current motor, taking current from the lines at from 400 to 700 volts. At rated speeds of 120 revolutions per minute, each unit has a capacity of 215 cubic feet of free air per minute compressed to 80lb. pressure. The compressors are automatically controlled and regulated by the air pressure. Working pressure on the system is maintained constant within 5lb. of the fixed standard. When the receiver pressure falls below normal, a combination of electrical circuits operates to bring the compressor to speed with no load, and then to cut out the starting resistance and throw off the load. When normal pressure is reached on the system, the machine is unloaded and the motor cut out. Arrangement is also made whereby the starting and stopping of the unit also automatically starts and stops the flow of intercooling water and lubricating oils. Compressed air for these machines, which are located in sub-stations along the subway, is distributed through 2in. pipe lines running the length of the system, and operates various signal mechanisms, pneumatic switches, automatic train stops, etc. The installation of these electrically-driven air-compressors with their automatic control and regulation is regarded as a great step forward in switch and signal work.

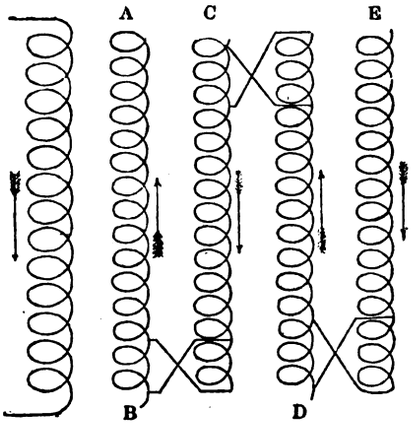
Electrical Production of Iron and Steel.—An extended enquiry as to whether iron and steel can be produced electrically in Canada at a profit has been conducted by Dr. Haanel, Dominion superintendent of mines, Mr. F. W. Harbord, an English metallurgist, and other experts. Mr. Harbord's conclusions are briefly as follows: Steel equal in all respects to the best Sheffield crucible steel can be produced either by the Kjellin, Heroult, or Keller processes, at a cost considerably less than the cost of producing a high-class crucible steel. At present structural steel cannot be produced to compete with Bessemer or Siemens steel. Pig iron can be produced on a considerable scale to compete with the blast furnace only when the electric energy is very cheap, and the fuel very dear; on the basis of 10dol. per horse-power per year and coke at 7dol. per ton, the cost of production is about the same as the cost of producing pig iron in a modern blast furnace. To sum up: Under ordinary conditions, where blast furnaces are an established industry, electric smelting cannot compete; but in special cases, where ample water power is available and blast-furnace coke is not readily obtainable, electric smelting may be commercially successful. Dr. Haanel, however, gives a more hopeful view, and says that where, as at Chat's Falls, near Ottawa, electric power can be produced at 16s. per horse-power per year, and peat coke or briquetted charcoal made from mill refuse, at a cost of not more than 16s. per ton, is used, the cost of two of the heaviest items entering into the production of pig iron is reduced by one-half. He concludes: "When it is considered that the electric process is applicable also to the smelting of ores, such as copper, etc., and that the furnaces are of simple construction, the temperature available, 1,000deg. C. above that of the blast furnace, and the regulation of the heat supply under perfect control, it is reasonable to expect that the near future will witness great strides in the application of electric energy to the extraction of metal from its ores, and that familiarity with handling large currents, and experience gained in electric smelting, will result in solving the difficulties encountered in the smelting of ores which up to the present time have proved refractory to all commercial processes known."

Mercury Sulphate and Standard Cells.—The *Zeitschrift für physikalische Chemie* has a contribution by Mr. G. A. Hulett upon the best method of preparing the mercury sulphate, an abstract of which appears in the *Journal* of the Chemical Society. It is known that the E.M.F. of the Weston cell varies with the method of preparing the mercurous sulphate required. The author has studied the extent of this variation, and recommends an electrolytic method of preparing the sulphate. Sulphuric acid is electrolysed with a platinum cathode and a mercury anode, and the mercurous sulphate formed is prevented by a stirrer from settling on the anode. When this mercurous sulphate is used in the preparation of a Weston cell, the E.M.F. is

Digitized by Google

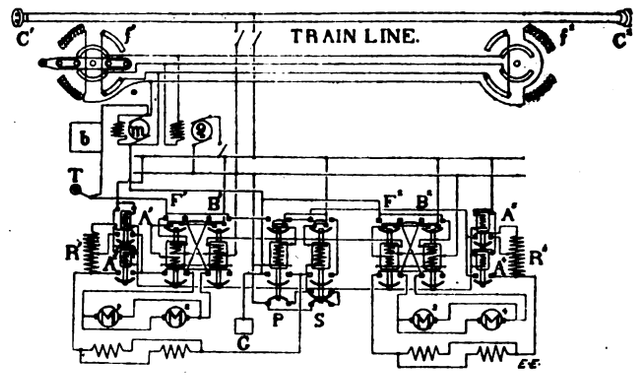
constant from the first, and has exactly the same value in different cells—namely, 1·01908 volts at 21·1deg. By shaking mercuric sulphate and dilute sulphuric acid with mercury for some time, the same equilibrium is reached as when mercurous sulphate alone is used. It is shown that mercuric sulphate is present in the cell, and analysis gives the ratio $Hg^{\cdot}/Hg^{\cdot\cdot} = 40$, a much smaller value than that found by Abel. The experiments indicate that mercurous sulphate is affected by the cadmium sulphate solution, and accordingly the hydrolysis of the former salt has been studied in detail. After prolonged shaking with mercury and water, the water being renewed at intervals, the residue has an exceedingly small solubility, and analysis indicates that the compound $HgHSO_4$ has been slowly removed and that the residue consists of a basic salt; thus: $3Hg_2SO_4 + 2H_2O \rightleftarrows (HgOH)_2,Hg_2SO_4 + 2HgHSO_4$. If this basic salt is substituted for pure mercurous sulphate as the depolariser in a Weston cell, the E.M.F. is considerably greater than the value given above. The author has determined also the solubility of mercurous sulphate in sulphuric acid solutions of various concentration, and finds a marked discontinuity at the concentration $v = 1$. This indicates that the mercurous sulphate used in the standard cells should be prepared from sulphuric acid of greater concentration than that just referred to. It is shown in the paper that mercurous salts may conveniently be estimated as chloride by precipitating with a slight excess of a dilute chloride solution and drying the mercurous chloride obtained in a vacuum desiccator for 12-24 hours.

Transformers in Series for High Tensions.—In a communication to the *Electritchestvo*, Mr. P. Kovalef makes a suggestion for obtaining high-tension current by a new method of employing several ordinary transformers. It is sometimes desirable to obtain a much higher voltage than that for which transformers at hand have been calculated.



To that end, Mr. Kovalef observes that the secondary wires of two or more transformers are generally connected in parallel with a source of low voltage, while the primary wires are connected in series. This manner of connecting, however, involves a high potential difference inside the separate transformers, between the high and low tension coils, and therefore it becomes a matter of risk to connect in series more than three transformers in order to obtain a voltage more than three times as high as the normal voltage of a transformer of a given type. The connection of transformers, illustrated in the accompanying diagram, gives a possibility of reaching much higher voltages. The low-tension winding of only one transformer is connected to the source of E.M.F., and the primary windings of the remaining transformers are left free, connections being established among the high-tension windings. Shunts are taken from these windings at equal distances from the end of each winding, say at one-sixth the total length. The manner of making these connections is shown in the accompanying figure. The second transformer is fed by the first, the third by the second, and so on. It will be seen that, notwithstanding the number of transformers connected in circuit, the inside tension in each of them will not exceed the tension between the extreme points of the winding, while the total tension of the whole circuit will be equal to the geometrical sum of voltage of all the transformers, considering, of course, the tension between the points B and C, C and D, D and E, etc. The above method may also be modified by using the secondary wires of the transformer. Mr. Kovalef acknowledges, however, that the question of voltage obtainable often becomes more complicated owing to the self-induction of the transformers, and the total sum of voltages differs greatly from their algebraic sum.

A Two-Wire Multiple-Unit System.—A patent has been granted in the United States to the Cutler-Hammer Manufacturing Company in connection with a new system for controlling motor-driven cars operated on the multiple-unit principle, a description of which appears in the *Street Railway Journal*. The unique feature of the invention is that both the direction and speed of the driving motors installed on the train are only controlled by means of two small wires running the entire length of the train, and by a controller of about the same size as a standard field regulator for a 3-kw. generator. The two wires constituting the train line are attached at each end of the car to automatic couplings, C^1 and C^2, which enable the cars to be shifted either end to. The maximum current carried by the two-wire train line is the output of a 3-kw. 110-volt generator when used in connection with six cars equipped with four motors on each car, capable of developing 300 h.p. per car. Each car may be equipped with a 3-kw. motor-generator, *m g*, capable of controlling the speed of the motors of the entire train, or by another method each car can be equipped with a ½-kw. motor-generator, capable of controlling the speed of its

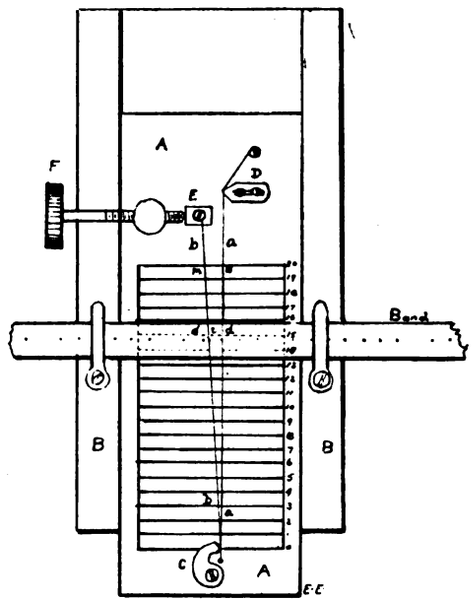


own car only. The direction of travel of the train is controlled by the direction of the current flowing in the two-wire train line, and the speed of the train is controlled by the voltage of the current impressed upon the two-wire train line. These wires are utilised for supplying the necessary current for energising the windings of a number of solenoid switches, which control the current supplied to the driving motors, M^1, M^2, M^3, M^4, mounted on the trucks. The two driving motors on each truck are treated practically as one motor, but are provided with an independent solenoid reversing switch, F B, and two solenoid accelerating switches, A, for cutting out the starting resistance, R. Two other solenoid switches, S P, are employed for connecting the motors on one truck, either in series relation with the motors on the other truck, or in parallel relation therewith, in accordance with the speed desired. Each solenoid used on the reversing switches, F B, is provided with two

Digitized by Google

windings, one of which is permanently connected between the trolley, T, or third rail, and the ground, G. while the other is permanently connected to the train line. The coil on the forward solenoid reversing switch, F, is wound left-handed, and that on the back-up solenoid reversing switch, B, is wound right-handed. Thus the operation of the reversing switches in accordance with the direction of the current flowing through the two-wire train line is simple. The accelerating solenoids and the series and paralleling solenoids are wound to actuate their plungers at different voltages. The system is worked by the operator starting the motor-generator by means of an ordinary 3-kw. 110-volt starting box, *b*. He then moves the field regulator lever, F^1, in the direction in which it is desired to move the train, and on this lever making contact with the first step of the resistance, current is admitted through the resistance to the shunt field of the 3-kw. generator, *g*, thereby causing same to impress a voltage on the two-wire train line of, say, 20 volts. This is sufficient to supply enough current to energise the forward reversing solenoids, F^1 and F^2, and to cause them to lift their plungers, assisted by the current taken directly from the trolley. The same voltage also supplies sufficient current to energise the winding of the series solenoid switch, S, which attracts its plunger and closes the circuit of the four driving motors, M^1, M^2, M^3, and M^4, in series relation. The operator then moves the 3-kw. field regulator to the second notch, which increases the voltage on the two-wire train line to, say, 40 volts, which is sufficient to energise the first of the solenoid switches, A^1, A^2, for cutting out the first step of starting resistances, R^1, R^2. The operator continues to advance the 3-kw. field regulator lever, thus gradually increasing the voltage on the two-wire train line, until finally the second step of resistances, R^1, R^2, is cut out. The paralleling switch, P, is then energised and the starting resistances, R^1, R^2, reinserted, the resistances being again cut out until the driving motors are finally operating in parallel relation at full speed.

An Electric Chronometer.—The Mors Company, so well known in the manufacture of automobiles, have brought ought an electric chronometer to supersede the old method of stop-watch timing for races and tests. The human element enters largely into the stop-watch method, seeing that the timekeepers are required to estimate the exact moment of the start and finish, and, moreover, stop watches in general will only register to one-fifth of a second, while in the electric chronometer the personal factor is eliminated, and the result is automatically recorded upon a band of paper, which the apparatus unrolls with an accuracy of the hundredth part of a second. The apparatus is set up at each end of the line, and connected by an insulated wire which is laid along the side of the route. A wire is stretched across the track at the point where the cars start. This wire is connected by a suitable lever with a contact which is mounted inside the apparatus. As the automobile passes over the wire the contact is established, and this movement is registered automatically by the action of an electromagnet upon a band of paper, which is unrolled in the chronometer. When the car arrives at the finishing mark, it passes over a second wire which is stretched across the route. A second current impulse is thus sent over the line into the chronometer box, and the exact time of the finish is registered. The strip of paper is unrolled during the passage of the car by a modified form of Morse register, which feeds out the paper at a practically uniform speed. The moment of starting and finishing is recorded by a needle-point which makes a dot upon the band, so that by taking the distance between the dots the time is obtained. Each one-fifth second is registered upon the band by a second needle-point, which the chronometer operates by means of an electromagnet, so that it is only necessary to count the number of spaces and fractions. In order to make the device thoroughly practical when out on the road, M. Pottier, one of the chief electrical engineers of the company, has devised a compact instrument (an illustration of which we reproduce from the *Electrical Review* of New York) for calculating the position of the recording dots within the spaces they occupy on the band, so that they can be read to one-twentieth of a space (which is 0·2in.) with accuracy, thus obviating a discussion while taking the reading. A brass plate, B, carries the paper band, which is held down by two clips. Below the band slides a second plate, A, which works in a groove in the former, making the surface of A flush with B. The second plate carries a series of parallel and equal divisions, which are numbered from 1 to 20. Below the scale are two fine wires, whose origin is made to coincide with division zero of the scale by means of the curved arm, C. The wire, *d*, on the right is fixed exactly perpendicular to the scale divisions, and is held at the top by a screw and an adjustable piece, D.



The left-hand wire, d_1, is held at the top in the sliding piece, E, and can be adjusted back and forth by turning the thumbscrew, F, thus making its angle with the first wire greater or less. To make the measurement the band is first brought so that the top edge of the paper corresponds with the upper division (No. 20) of the scale. The band is now moved to one side so that right-hand chronometer dot is brought just under the fixed wire, *a*. The movable wire is now adjusted by the thumbscrew so that it coincides with the left-hand chronometer dot. That is, the distance M N on line No. 20 is the measure of the regular time space on the band. It only remains to slide the plate carrying the band until the left-hand wire, *b*, comes over the time dot, *t*, which has been made by a solenoid mounted above the registering apparatus for the purpose. The dot, *t*, lies in the interval, d_1 *d*, and it is this interval which it is proposed to measure. Supposing the wire to coincide with *t* when the band has been lowered to division No. 16 of the scale, the position of the dot is therefore read to sixteen-twentieths of the interval, or $\frac{16}{20} \times \frac{1}{5}$ second = 0·16 second. The position of the corresponding time dot at the other end of the band is then read in the same way as the first, and the two fractions of a space are added to the whole number of spaces between the time dots, thus giving the exact time.

THE ELECTRIFICATION OF THE METROPOLITAN RAILWAY.

(Concluded from page 918.)

The switchboard arrangements at Neasden are most interesting, and show a complete departure from the older method of arranging the controlling apparatus and measuring instruments on a vertical series of slate or marble slabs. A departure from this system is necessitated both by the high voltage of the three-phase system and by the large switchgear needed by the size of the generating units. The scheme adopted by the Westinghouse Company at Neasden embodies their latest improvements for the remote control of this switchgear by means of electric motors or solenoids. The main control board (Fig. 19) is of the now very general desk type, with an inclined top. On this is fixed the remote control apparatus for operating the main alternator, feeder, and field switches, and the electrically-operated resistances and turbine governors. On the top of the desk is drawn a diagram of the connections, showing the generators, 'bus bars, and switches, and thus the attendant has always before him a clear representation of the conditions under which the station is working—a very commendable feature, and one that might be adopted with advantage in all stations of any considerable size. The switches are all worked by solenoids off a 125-volt direct-current circuit, and for the field rheostats motor control is used. The small motor on each regulator is geared down to work the sliding contacts. At either end of the motion there is a trip mechanism which opens the motor circuit and prevents it running against the stop.

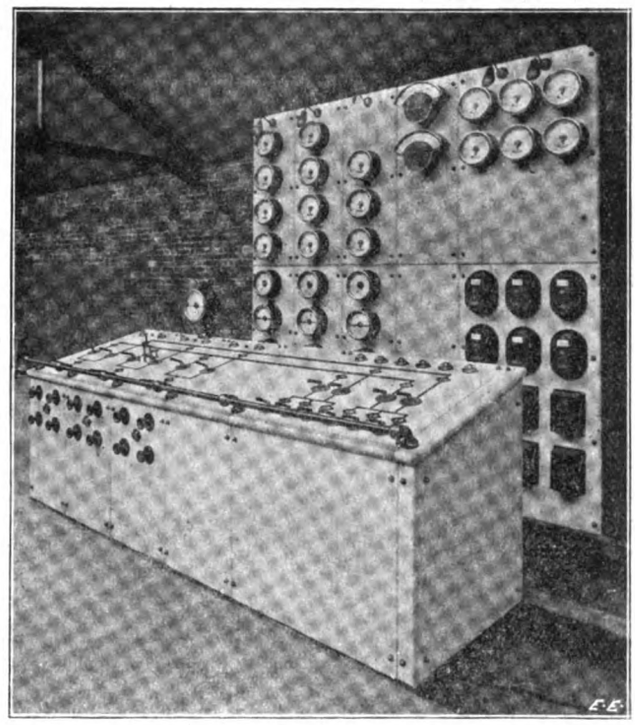

FIG. 19.—The Main Control Board at Neasden from which all the Switchgear is operated.

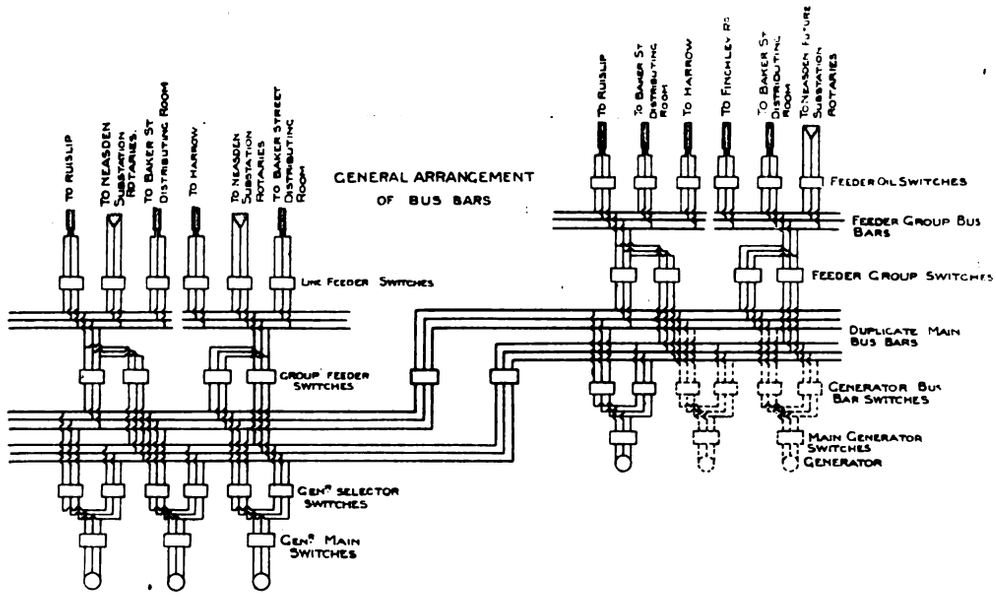

20.—Diagra of the Duplicate 'Bus Bars at Neasden for the Group Control of the High-Tension Feeders.

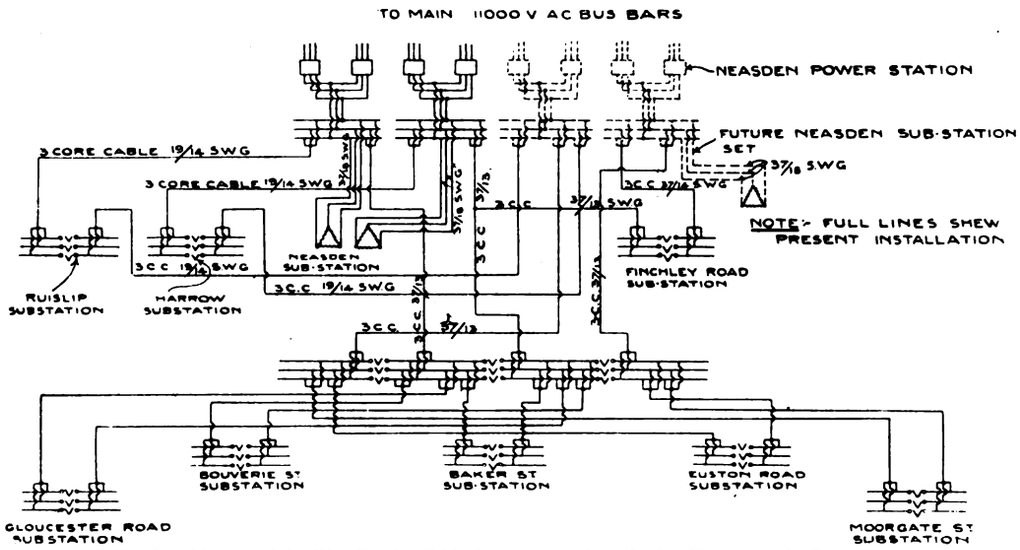

FIG. 21.—Diagram of the High-Tension Cable System connecting the Sub-Stations to the Power House.

The actual arrangement of the 'bus bars for securing continuity of supply under all circumstances is shown in

Digitized by Google

Fig. 20. From this it will be seen that the Westinghouse Company have provided duplicate facilities for the splitting up of the load into groups. For instance, there are two complete sets of main 'bus bars, to either of which each of the generators may be connected by the aid of the switch-gear. There are in each generator circuit two switches in series—the one next to the machine a simple main circuit oil-break switch, and the other, between this and the 'bus bars, the selector switch for connecting the generator to either set of 'bus bars In addition, isolating switches are provided and placed electrically right on the 'bus bars to allow for safe inspection or repair of the controlling apparatus. By closing both of the selector switches it is possible to operate with both sets of 'bus bars in parallel. The same arrangement holds good in the feeder circuits, which, as shown, may be connected to either or both sets of bars.

On the separate rheostat, or control board, there is a duplicate set of direct-current 'bus bars, from which the exciting current is taken through two main double-pole, single-throw, quick-break switches to the generator field. These two switches are electrically operated, and may be used either singly or in parallel. In connection with them the usual discharge resistance is provided, and a field ammeter and an electrically-operated regulating resistance completes the equipment for each generator exciting circuit.

For each of the generators the following measuring instruments are provided, arranged in a vertical line behind the marble desk from which the machinery in the station is controlled: an alternate-current voltmeter; three alternate-current ammeters, which are supplied through series transformers linked respectively round each of the three main leads from the three-phase alternator; an indicating watt-

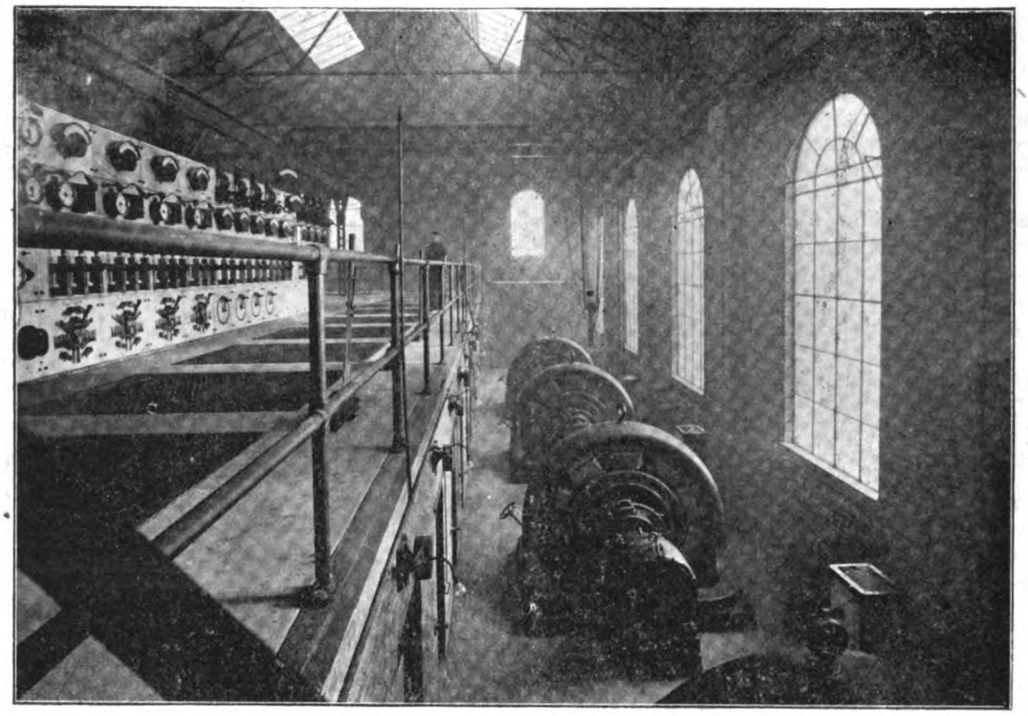

FIG. 22.—Typical View of a Sub-Station on the Metropolitan Railway.

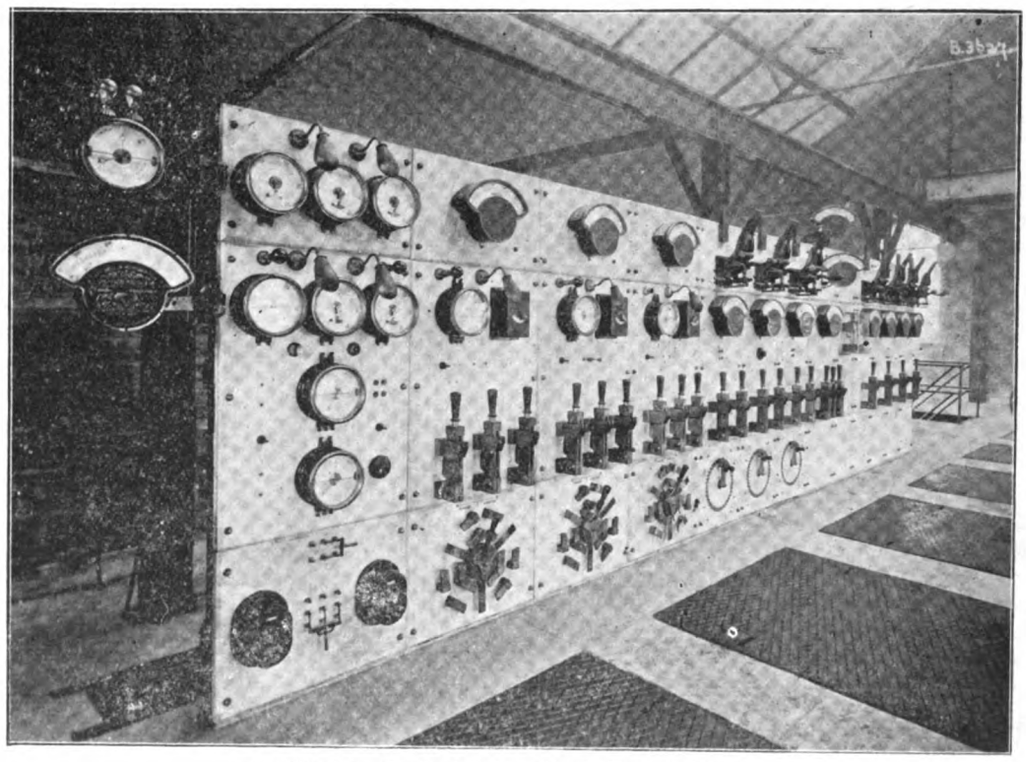

FIG. 23.—A Low-Tension Switchboard in the Harrow Sub-Station.

Digitized by Google

meter; a power factor meter; and a direct-current ammeter for the exciting circuit. These power factor meters are exceedingly useful when two machines are connected in parallel, as they enable the operator to see when the alternators have their right excitation, etc., and are all giving supply to the 'bus bars with the same power factor. While the indicating wattmeter, in conjunction with the ammeters and voltmeter, enable the same adjustment to be made, it can only be done after a calculation, which should not be required from the switchboard attendant. The electric control circuit is worked at 125 volts direct current, and the controlling handles are placed at the front of the marble desk on the vertical face of the same. As the potential of the current controlled by this switchboard is 11,000 volts, fireproof construction, safety, and convenience of working have been the leading consideration in their design, and all these conditions are amply met by most efficient means. The 'bus bars and other conductors are supported on heavy porcelain insulators, and where a difference of potential exists, are separated by means of fireproof and insulating walls. All conductors are placed so as to offer the least risk to the switchboard attendants, but at the same time they are arranged to be readily accessible if necessary, and fully in sight. In the lower gallery the 11,000-volt generator and feeder main circuit oil switches are placed, and in the gallery above them the selector switches previously referred to. The top gallery contains the main alternating-current 'bus bars and the various instrument and control boards. All the boards are of white marble, of beautiful appearance, and the characteristic finish of the British Westinghouse Company. They may be taken as thoroughly representative of the best modern practice in which breakdown, fire, and shock risks are reduced to an absolute minimum, in conjunction with the greatest simplicity and ease of working.

The same care which has been shown in duplicating the switchboard arrangement has also been adopted in connection with the high-tension feeders to the various sub-stations. The actual position of these sub-stations and the output of the rotary converters in each was given in our issue for Dec. 16. A diagrammatic plan of the cables to these sub-stations is shown in Fig. 21, which gives the actual size of the cables in each case. From the power station four cables run to Harrow, two of which continue to Ruislip. In the other direction five run to Finchley-road, where one ends and another is tapped off, continuing its course with the remaining three to Baker-street, where they terminate. From Baker-street eight cables run to the other four sub-stations of Gloucester-road, Bouverie-street, Euston-road, and Moor-

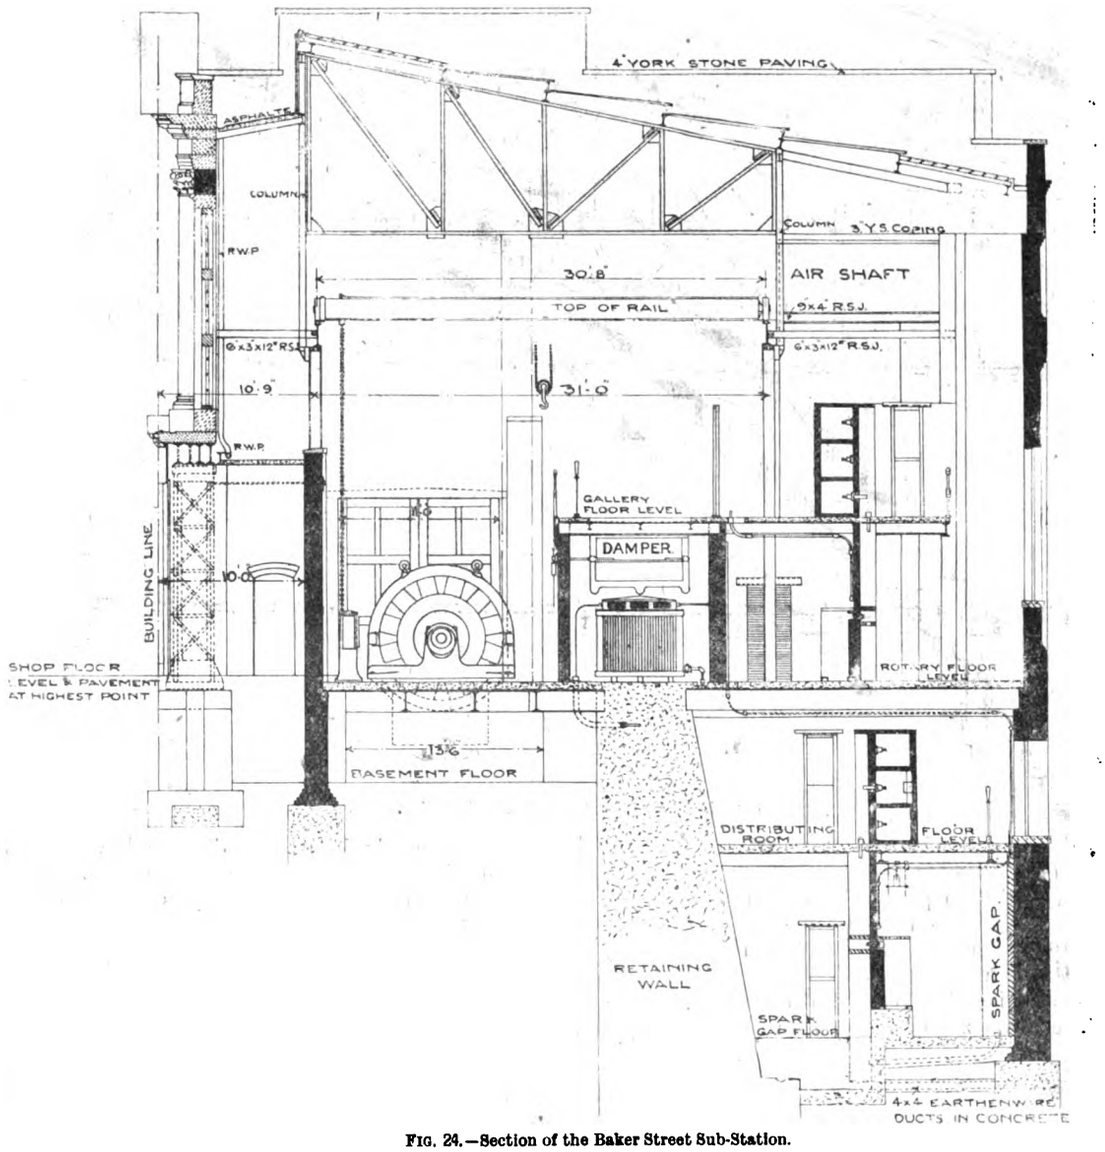

FIG. 24.—Section of the Baker Street Sub-Station.

gate-street—two feeders to each. Thus Baker-street, when finished, will be a highly important station, as it will control all the Metropolitan Inner Circle traffic. It will be seen that every sub-station is supplied from two independent feeders, which will naturally be connected on to different groups of the generating plant when the whole station is completed. The whole of these cables for working at 11,000 volts have been supplied and laid by the British Insulated and Helsby Cables, Limited. The cables are all of the three-core type, paper insulated, lead covered, and armoured. They have been laid on the solid system from Uxbridge to Finchley-road, and on brackets in the tunnels from Finchley-road to Baker-street and on the Inner Circle. This high-tension system has required about 75 miles of three-core cable. The same firm have also supplied all the low-tension, rubber-insulated, lead-covered cables for making the connections to the third and fourth

Digitized by Google

rails at various parts of the system. They have been responsible for the laying of the cables, and also for the connecting up, and their resident engineer for the work has been Mr. F. Bradford.

As mentioned in our last issue, the three-phase 11,000-volt current is transmitted to the sub-stations, and there

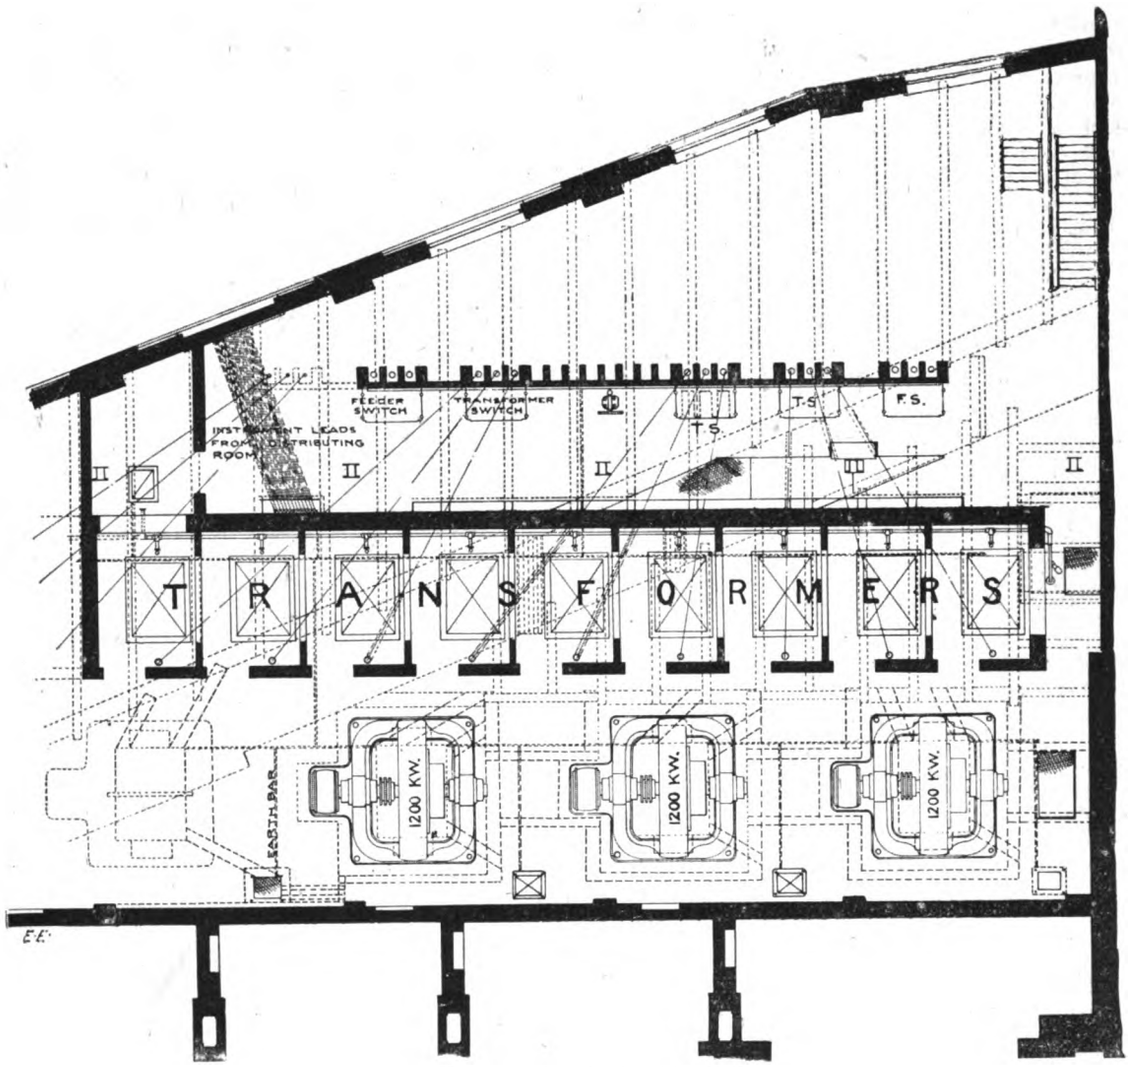

FIG. 25.—Plan of the Baker Street Sub-Station.

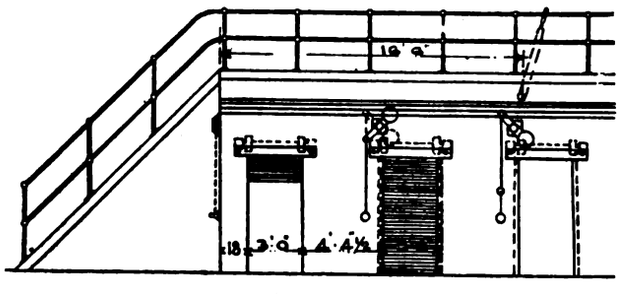
transformed down and changed to direct current at approximately 600 volts by means of rotary converters. Though the sub-station equipments vary in size according to their position on the line and the load that they will have to carry, the plant is identical in type and as far as possible in arrangement, having all been designed and installed by the British Westinghouse Company. The two sizes of rotary converters employed,



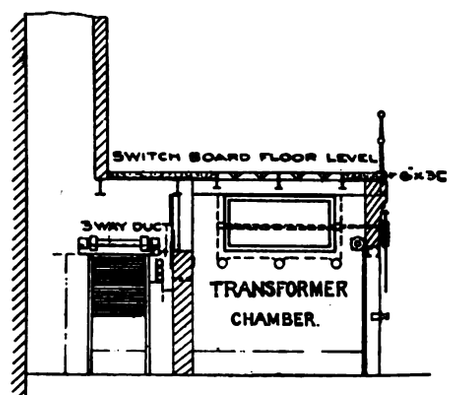


FIG. 26.—Details of the Transformer Chambers, showing Fireproof Roller Screens.

800 kw. and 1,200 kw., have respectively 10 and 12 poles, and run at speeds of 400 and 333·3 revolutions per minute. The transformers used in connection with them are of 300 kw. and 435 kw. capacity per phase, and are of the insulated self-cooling type. A good idea of the general lay-out of the sub-stations is conveyed by Figs. 22 to 25. The rotaries occupy the ground floor, and in some cases a railway siding is brought right into the building in order to facilitate the erection and replacement of machinery. The switchboards, oil switches, and transformer chambers take up by far the greatest space, and are arranged in the manner indicated in the drawings. Each transformer is placed centrally in a separate well-ventilated chamber with its low-tension side facing the door, and a large air-shaft common to all the chambers provides for a through draught. In the ceiling of the chambers, which is the floor of the upper gallery, large iron manholes are inserted to allow of the transformers being withdrawn if necessary, a hand-power travelling crane being in most cases provided for this and other similar purposes.

On the ground floor behind the transformer chambers is a passage containing the high-tension oil-break switches, and at the back of this are the cable ducts, through which the 11,000-volt feeders enter the building and the track feeders leave it. The lightning arresters are

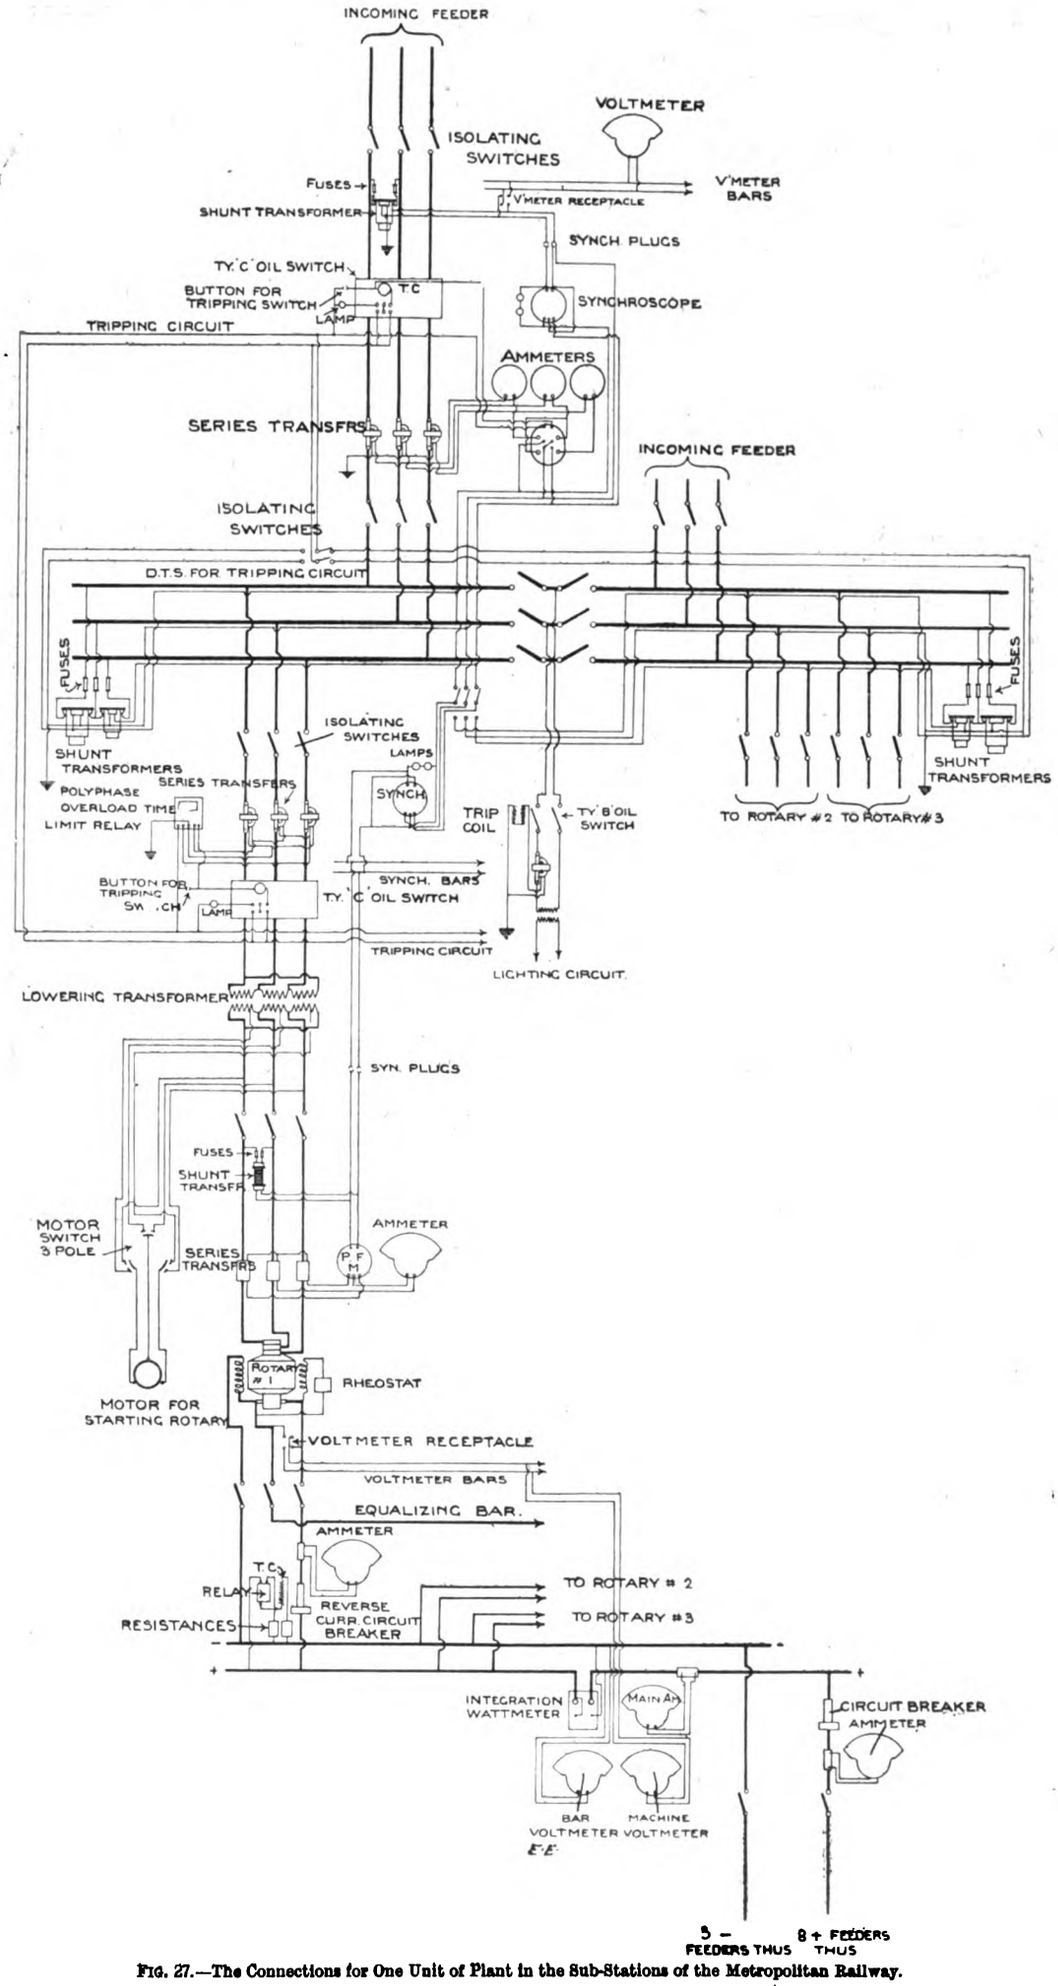

FIG. 27.—The Connections for One Unit of Plant in the Sub-Stations of the Metropolitan Railway.

situated here on the end of each cable in separate brick partitions. All the high-tension switches are hand-operated through gearing by means of levers placed close to the edge of the upper gallery, and in the case

Digitized by Google

of those used in the rotary circuits are provided with time-limit relays, while automatic reverse-current relays are installed with the feeder switches. Electrical tripping arrangements are placed both on the switchboard panels on the gallery and the main levers. The high-tension 'bus bars of thin copper strip are contained in brick chambers situated directly over the oil switches. They are supported on substantial and effective insulators, and access is obtained to them through iron doors, which when closed render them inaccessible. The low-tension and operating switchgear is contained on several marble panels placed well in front of the 'bus bar chambers in the upper gallery. They are very ornamental in appearance and quite simple in electrical design. Referring to the illustration (Fig. 23) of the Harrow board, the first panel on the left contains sundry measuring instruments, synchroscopes, etc.; the next three, the rotary converter alternating-current side, starting, motoring, and switching gear. Following these are three panels for the direct-current side of the rotaries, containing circuit breakers, shunt regulating resistances, etc., and next the 11,000-volt feeder and four-track feeder panels. The lighting of each sub-station is effected from a separate small transformer tapped direct off the feeders, and in addition an efficient gas supply is laid on to cope with the remote possibility of entire failure of the current. This latter point is an example of the great care and forethought that has been brought to bear on the design and construction of the sub-stations, where reliability has been made the essential feature; every possible accident or derangement has been foreseen and provided for. The

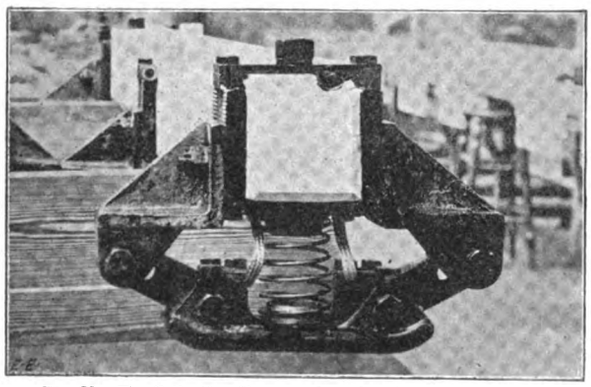

FIG. 28.—The Collecting Shoes used on the Metropolitan Trains.

drawings we reproduce in Figs. 24 and 25 are of the sub-station at Baker-street, where there was considerable difficulty in finding the space required for the apparatus. The arrangements, therefore, are not quite so symmetrical as in other sub-stations where there was ample room available. In Fig. 27 we give a complete diagram of connections of a unit of plant in a sub-station, which our readers will be able to easily follow.

We described the rolling-stock as far as it affects the creature comforts of the public in our issue for Dec. 16, and in our issue for July 29* will be found a complete description of the electro-pneumatic control as used on these trains. A few further details, will, however, be of service here to render our article more complete. Each motorcar, of which there are two in a train of six coaches, is equipped with four 150-h.p. iron-clad British Westinghouse railway motors, one for each axle of the truck. There will, therefore, be the unusual amount of 1,200 h.p. available for propelling each train. The collecting gear carried on the motorcars is shown separately in Fig. 28, in which it will be noticed that the working parts are effectively shunted by flexible copper connections. This gear is installed on both sides of the motorcars, as the current rail is not always on the one side, and a similar arrangement is fixed to a beam in the centre of the truck for making contact with the return rail. The Westinghouse quick-acting brake is fitted to all the trains, and works automatically in conjunction with the unit-switch arrangement. Both the power and lighting wiring of the cars is carried out upon the soundest principles, with all conceivable precautions against fire. The method is illustrated in Fig. 29, which shows some of the cables laid in asbestos grooves, filled in with a fireproof composition and covered with sheet asbestos. All the rolling-stock has been built at Birmingham and Manchester by the Metropolitan Amalgamated Railway Carriage and Wagon Company, Limited, under the immediate supervision of the railway company's carriage and wagon superintendent, and the entire electrical equipment has been designed and installed by the British Westinghouse Company.

For the actual details of the train control we would refer our readers to our previous description, which was fully illustrated. We reproduce, however, in Fig. 30, a photograph of the small master controller in position in the driving compartment of the train. This small controller, working on a 14-volt circuit, operates the needle air valve of the turret controller. The current for this circuit is taken from a 14-volt battery of accumulators, which is kept in series with the lighting wires on the car. This precaution ensures that the accumulators are fully charged. This controller has five notches for both forward and backward running, in addition to the "off" or neutral point. The movement of the controller handle to the first

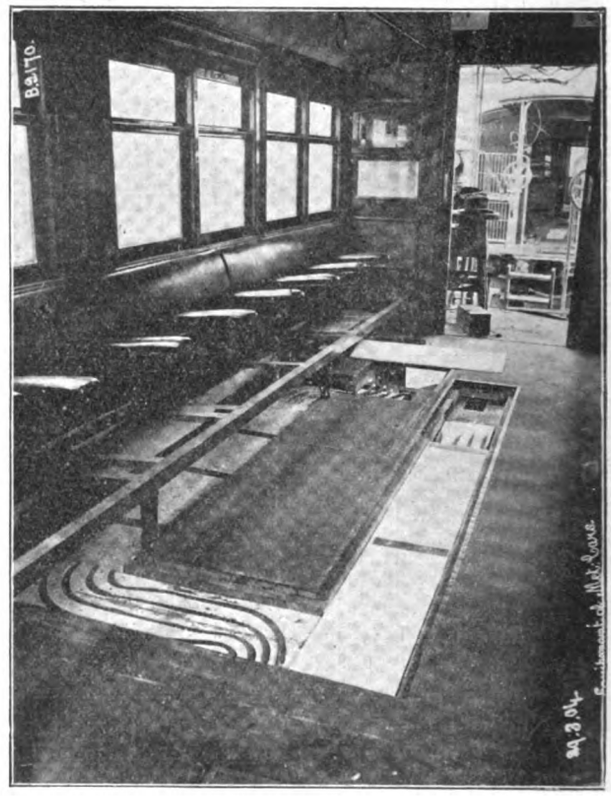

FIG. 29.—Interior of Motor Coach, showing the method of Fireproofing the Wiring.

stop sets the emergency brake valve; the second sets the reverser (a piece of apparatus for controlling the direction in which the car is run), and puts on the main supply current; the third, or shunting notch, connects the motors in series with all resistance in; the fourth brings the automatic accelerator into play, which closes the switches of the turret controller in their right order, unless checked by what is termed the limit switch; and the fifth, opening all the pneumatic switches that have been closed and simultaneously throwing in others, connects the motors in the first parallel stage with resistance in circuit. After the movement of the master controller to the fifth notch has effected the change from series to parallel, the automatic accelerator again comes into play and limits the rate at which the necessary changes in connections are made to attain full speed. The overload and no-voltage return relay is in electrical connection with the actuating magnet of one of the pneumatic cylinders of the turret controller which operates the main circuit breaker. To prevent damage from a resumption of supply after any interruption, such as a break in the third rail or persistent bad contact in the collecting shoes, the no-voltage part of this device returns the controller to a position in which some considerable amount of resistance is in circuit, allowing

* *Electrical Engineer*, vol. xxxiv., p. 153.

Digitized by Google

it to be gradually and automatically cut out when the current comes on again. Sudden interruptions and resumption of supply, such as occur when the collectors pass over points or crossings do not affect the relay, it being arranged to work too slowly for this.

Three of the most important points in the control equipment of these cars that are ingenious and have been found to be useful are as follows: The possibility has been recognised that through accident or sudden illness the motorman may leave hold of the controller handle, in which case, especially under the latter circumstance, grave consequences may ensue. This is provided for by means of a strong spring action, which, when the handle is released, returns it to the neutral position, interrupting all the electrical circuits, and causes the brakes to be immediately applied over the full length of the train. In ordinary reversing of the train this arrangement does not operate, provided the handle is passed quickly over the neutral point. The second safeguard is that which prevents any harm being done to the motors if the operator moves the controller handle rapidly over to the full parallel position. In such a case the speed

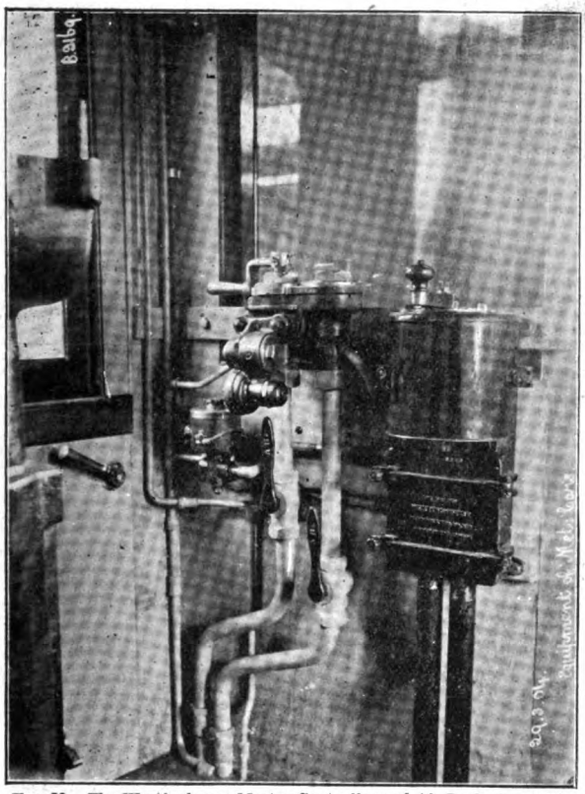

FIG. 30.—The Westinghouse Master Controller and Air Brake in position in the Driver's Compartment of Motor Coach.

of working of the turret controller does not increase, and the various connections passing from first series to full parallel are made automatically at the right pace. This reduction of the human element to a very low value results not only in greater safety and comfort to passengers, but in considerable economy in power consumption, amounting to as much as 10 or 15 per cent. over that obtained by ordinary hand-operated methods. The third provision is a system of interlocking between the control equipment and the power brakes, whereby the controllers throughout the entire train are opened automatically when the brakes are applied, no matter in what position the driver may have or continue to hold the master switch handle.

We have described above the excellent equipment with which the Metropolitan Company hope to more than recover the traffic which has been lost due to competition from the Central London Railway and electric tramways. The laying down of such a large plant, both in the power-house and in the sub-stations, is no light task, and it has involved heavy work on all concerned. Mr. Thomas Parker, M.I.E.E., has been the company's consulting engineer for the work, and he has been assisted by his son, Mr. E. T. Parker. We are indebted to these gentlemen for a great deal of the information given herewith, and for the loan of drawings from which our illustrations have been prepared, and for their courtesy in showing us the Neasden station and train equipment. It is only to be expected that Mr. Thomas Parker, with his pioneering experience in tramway and railway work, should have been called in to assist in this undertaking.

On Mr. A. C. Ellis, the general manager of the company, has fallen the work of organising the conversion of the line. Mr. C. Jones has been appointed the chief electrical engineer to the company. The work on the line has been carried out under the direction of Mr. E. P. Seaton, the company's engineer, and Mr. A. Ingram has supervised the construction of the new rolling-stock. These gentlemen and the contractors, the British Westinghouse Company, have now before them the difficult task of changing over the service from the one system to the other without interrupting the regularity of the running. It is convenient that the line to Uxbridge should be first to change over, as this will allow of full proof being made of all the new rolling stock before it is introduced into the Circle schedule, where an interruption would be much more serious. It is pleasing that the end of 1904 should mark the beginning of a change which in the coming year will render the tunnels between Baker-street and King's Cross habitable.

AMERICAN OIL-ENGINE CENTRAL STATION.

BY FRANK C. PERKINS.

The oil-engine has had the most wonderful development during the past decade as well as the internal-combustion gas-engine, and many plants are now being installed in this country as well as in Europe. The accompanying illustration (Fig. 1) shows a recent gas-engine electric light plant at Jewett City, Connecticut, while Figs. 2 and 3 show the details of construction of these most interesting engines.

This oil-engine is operated on the four-stroke or Otto cycle, and differs from other internal-combustion engines in compressing a full charge of air to a point above the igniting point of the fuel, then rejecting this fuel for a certain period into this red-hot air, where it burns with limits of pressure and temperature under perfect control.

The engines installed at the Jewett City electric light plant have each a capacity of 75 b.h.p. and 100 i.h.p. They are of the vertical marine type with triple cylinders, as mentioned above, with a 15in. stroke, and cylinders 10in. in diameter. In this plant there are two 50-kw. Westinghouse alternators of the single-phase type, supplying a current of 2,200 volts pressure and a frequency of 60 cycles per second. A direct-current exciter is belt-driven from each of these machines. These exciting dynamos each have a capacity of 1·5 kw., and supply a current of 125 volts when operating at a speed of 1,300 revolutions per minute.

The method used for lubricating the cylinders is automatic, and is not connected with other engines. Beneath each cylinder, housed in by iron-plate doors, is an oil well into which the connecting rod crank end plunges, slushing the oil into the cylinder at every stroke. By this means of lubrication the wear on the inside of the cylinders is very slight. There are two storage tanks, provided with a capacity of 6,500 gallons. These tanks are placed under ground, and contain crude petroleum, which costs, delivered, 4·6 cents per gallon. This is received in tank-cars in 6,000 gallon lots, and is drawn to the tank by tank-wagons, and the oil is pumped from the storage tanks into a feed tank above the engine which has a capacity of 40 gallons.

A wooden tank of 7,000 gallons capacity is located outside of the building, and furnishes a continuous flow of water through the cylinder jackets for cooling purposes. Pumps are provided beneath the floor to fill this tank, and they are operated from the main shaft of the engine, the water being taken from the pond below.

In reference to the economy of operation of this plant as to fuel and labour, it may be stated that one of the engines consumed an average of 38 gallons of oil for 12 hours' run, with an average output of 55 h.p. This engine and dynamo was used for doing commercial and street lighting, and the cost of operation, it is claimed, was

Digitized by Google

693dol. 50 cents for one year. In this estimate the oil was taken at 5 cents per gallon, making the expense for fuel 15⅝ cents for 55 h.p. per hour, or 1dol. 90 cents for 12 hours.

An engineer of Jewett City places the lowest possible amount of coal used to run a slide-valve steam-engine—not high speed—at two tons for 55 h.p. for 12 hours, which would cost, at 4dol. per ton, 8dol. per night. It is estimated that—with the services of a fireman, who would be needed, at 1dol. 50 cents per night—the total cost would be 3,367dol. 50 cents per year. It is suggested that in cold weather pipes can be attached to the cylinders of the engine and the heat used for radiation.

The gas-engine or oil-engine electric light plant is certainly a most compact equipment, and the engine-room and entire installation may be kept extremely neat and clean at all times, as no boilers, smokestack, coal-bins, stokers, heaters, or ashes are at hand, while the fuel expense begins only when the engine is started, and stops as soon as the valve is closed.

Two 50-kw. Westinghouse single-phase dynamos at the Jewett City electric light plant are belted to the oil-engine.

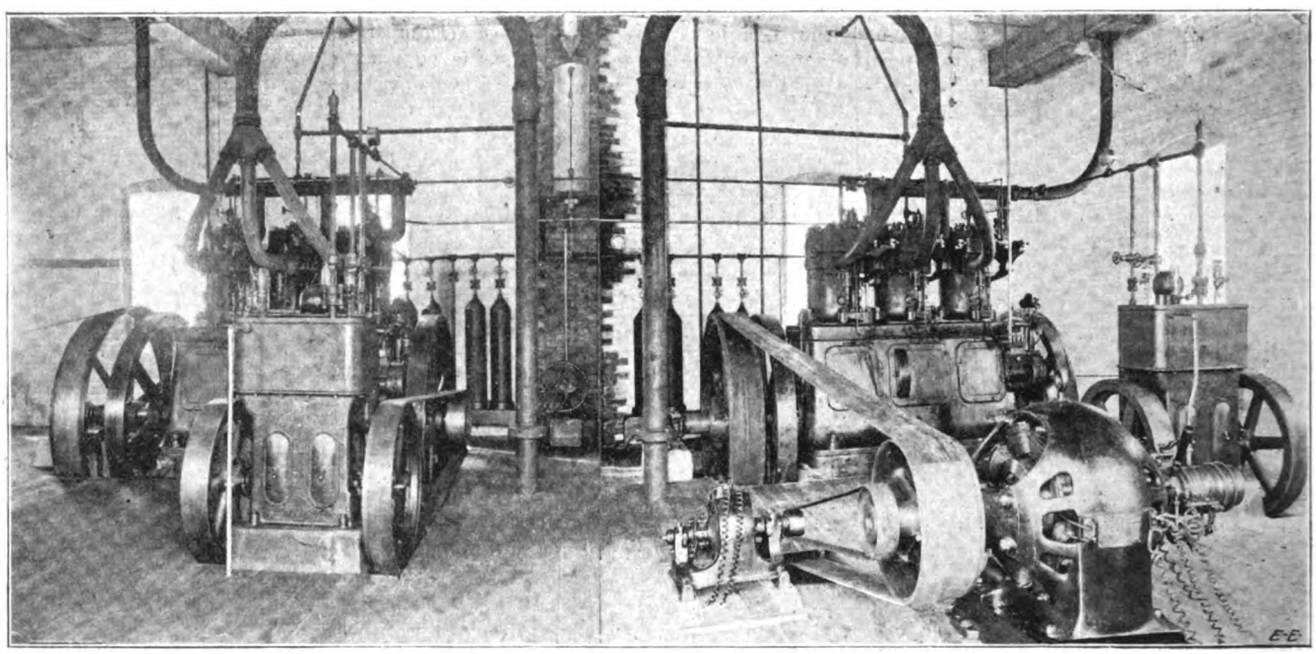

FIG. 1.—Jewett City Electric Light Plant, using Diesel Oil Engines and Westinghouse Single-Phase Alternators.

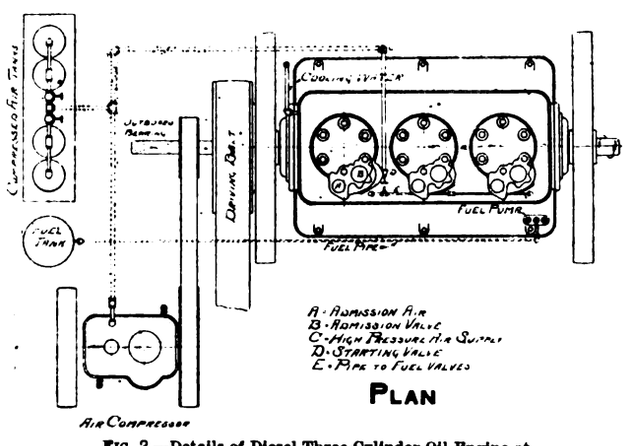

FIG. 2.—Details of Diesel Three-Cylinder Oil Engine at Jewett City Plant.

The wiring from the alternators is carried under the floor to the switchboard, and the 2,200-volt circuits are run in lead-covered cable. The switchboard consists of two panels of marbleised slate 8ft. long and 5ft. high, mounted on a frame of steel tubing. Each of these panels is supplied with a voltmeter and ammeter, as well as a double-throw double-pole interlocking switch for connecting the commercial lights to the generator, also the usual circuit breaker. The lighting system of this town includes about 2,000 incandescent lamps of 16 c.p. each, and 100 5·5-ampere incandescent street lamps.

THE EDUCATION OF BOROUGH COUNCILLORS.

[COMMUNICATED.]

There are certain terrors incidental to the popular control of technical business undertakings which are absent from the minds of men who manage the operations of private engineering companies. In the latter case the non-technical shareholders generally recognise their limitations, being induced to do so by an immediate sense of the pecuniary rightness or wrongness of their procedure. The technical staff is therefore given a much freer hand than is sometimes the case in municipal concerns, where the money value of a mistake is only distributedly felt through the medium of an increased rate. There is a great temptation to a borough councillor, elected for a comparatively short period of authority, to proceed somewhat beyond the limits of his knowledge in the attempt to accomplish something which will place garlands of local glory upon his brow.

It is therefore hardly to be wondered at that the relations existing between borough councillor and engineer are

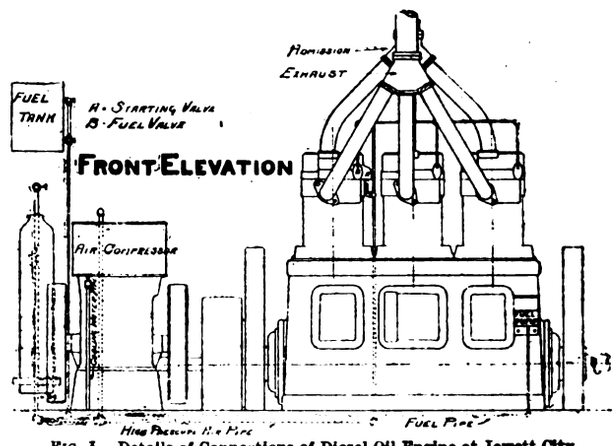

FIG. 3.—Details of Connections of Diesel Oil Engine at Jewett City Electric Plant.

not always of the happiest. The engineer, strong in the consciousness of a special knowledge, combats any interference with the satisfactory performance of the work under his control. The councillor, winning his seat through mazes of impassioned oratory, caustic criticism of accounts, and fervent promises to inaugurate the millennium, is not the man to be "drowned" by a condescending explanation of the reason why apparent black is in reality white, delivered by a gentleman whose technicality is far in excess of his salary. The result is the production of such unfortunate *impasses* as recently occurred in one of our

Digitized by Google

metropolitan boroughs. Sympathy with or denunciation of either party is of no value in such a case. The question, a solution to which is more or less urgently required in every part of the country, is: What can be done to produce sympathy of feeling and, if possible, a common point of view for councillor and engineer?

There is no doubt that the Municipal Electrical Association is doing splendid work in this direction by means of its conventions for the inspection of works and the reading of papers bearing on the business and engineering aspects of municipal electrical undertakings. Its effect on the mutual esteem of those gentlemen holding responsible positions who attend these conferences must be very marked, and the severer exercises are judiciously tempered with certain social functions which display to the participants amiable qualities in their fellow-men, the recollection of which may serve as oil on the troubled waters of debates in committee. But not every member of an electric light or electric tram committee can spare the time to run away to the other end of the country for a week of electrified reunion. What is to be done with those councillors who prefer to stay at home and address their constituents?

Briefly, the remedy would seem to be to take advantage of their natural inquisitiveness. A borough councillor who is not anxious to visit the electric light works, to inspect the same, and to ask the greaser if there is anything wrong with the boilers, is inexplicably lacking in initiative. Moreover, if the engineer exhibits symptoms of resentment, the councillor will not desist, but will try to dodge the engineer by calling at unexpected times in the hope of finding out what it is the engineer is trying to hide.

The committee should be encouraged to inspect the works *en bloc*. The individual asperities of the members are modified by combination in very much the same way that a composite photograph presents a much softer outline than any of its component facial representations. A councillor surveying the station alone is apt to imagine himself the "cock that craws on his ain dunghill"; when in company with others he is less assertive. Moreover, the individual stocks of technical intelligence are pooled; the engineer has less popular lecturing to do, and time is economised.

Having, then, got your councillors together, nominally for a tour of inspection, really for a course of instruction, how are you to administer the medicine so that they may have no suspicion that they are being dosed, but rather that they are feeling your pulse? Bare-faced lecturing will not be tolerated; deferential requests for exchanges of ideas let loose the floods of amateur criticism. The best method is probably to turn the generating station into a temporary electrical exhibition for the benefit of the councillors.

Perhaps this may be best illustrated by detailing a very successful process to which a newly-elected electric light committee was subjected by one of our borough council engineers. The members of that committee were of the native-intelligence order. Their business capabilities in their several trades were undoubted; their knowledge of local conditions and facility for expressing the same made them respected of the populace and a power in debate. Their acquaintance with technical matters was, however, superficial. The borough engineer opened fire upon them by inviting them to a species of state inspection of the works, the committee being asked to assemble at a fixed hour in the general office of the station. On arrival they were severally presented with a neatly-typed itinerary, of which the following paragraphs are typical quotations:

"*Test-Room.*—Here will be seen a collection of mains accessories, including feeder pillar, section box, samples of feeder, network and house service cable, a meter board complete with fuse box, meter and demand indicator similar to those installed on consumers' premises. Tests will be made on the efficiency of incandescent lamps by the aid of the photometer during the committee's inspection of this part of the works. The testing set used for the location of faults in cables will also be exhibited."

"*Engine-Room.*—Entering the engine-room from the pump-house, the three Belliss triple-expansion engines will be seen, each having its own condenser and air and circulating pumps." (Particulars of the horse-power, revolutions, etc., follow.) "To the right are two Willans triple-expansion engines, the enclosed moving portions of which are lubricated by the action of the cranks splashing in an emulsion of oil and water. If the state of the load on the station permits, one of these engines will be run round slowly with inspection doors removed, when the lubricating action can be observed."

"*Switchboard.*—This, which faces the dynamos, controls the entire works output. Cables are led to the board from each machine, and the current is then distributed to the mains feeding the load in different parts of the borough. These mains or 'feeders' convey the electrical energy from pairs of switches on this board to the following points, where they are joined to the distributing network through a feeder pillar or section box such as those shown in the test-room." (Here follows a list of the feeding points of local interest only.) "The regulating panel has mounted upon it four voltmeters, two for showing the actual pressure of the machines and 'bus bars at the station, and two for indicating the pressure at the feeding points. The latter object is accomplished by running back three small conductors called pilot leads, which can be connected to the two voltmeters at will, and it is by keeping a mean pressure on the various feeding points in the district that the regulation of the supply is carried out."

In the boiler-house attention was drawn to chain-grate stokers, and samples of condensed water before and after treatment with aluminoferric were shown, a succinct account of the process being given in the itinerary. One of the filters was open for inspection, and samples of the filtering material before used and after some days' running were shown.

The offices were likewise included in the exhibition, for here an arc lamp similar to those used in the streets was hung up, the casing being removed to show the mechanism. Moreover, the image of the arc was projected on to a screen, a caution being thoughtfully included on the programme to the effect that "It will be noted that the projected image of the arc on the screen is inverted owing to the action of the lens." In another part of the offices four incandescent lamps—two new, two blackened—were glowing in front of white card screens. Concerning these the councillors were informed: "Two efficient incandescent lamps are here shown consuming between them one unit in 7½ hours. Beside them are two inefficient lamps, which it will be noted are giving considerably less light and which are consuming one unit in six hours." A small display of Nernst lamps was also made, with the comment that "It is expected that this lamp will take a similar position in the electrical industry to that occupied by the incandescent mantle in gas lighting."

The borough engineer added one final touch which partook of the wisdom of the serpent. Mindful that medicine, even if administered in pilule form, is much more acceptable if sugar-coated, he influenced the chairman of committee to such an extent that on the return to the offices the councillors were gratified with a simultaneous offer of cigars and other comforts, and an appeal as to their opinion of the working of the station. The engineer afterwards put it on record that it was the most entirely enthusiastic committee he ever had the pleasure of meeting. Moreover, as each councillor went away with just that *soupçon* of technical knowledge that so admirably equips the usual canvasser, the borough engineer had in effect turned loose on the borough a dozen or twenty enthusiasts for electric lighting able to speak with exactly that technico-business manner which carries conviction to the man with the gas bill he doesn't like.

APPOINTMENTS VACANT.

Electrical Engineer, Hanley Corporation. Salary £300, rising to £350 by annual increments of £10. Applications to Town Clerk by Jan. 10. See advertisement in last issue.

Junior Assistant, King's Lynn. Commencing salary, £65 per annum. Applications to Borough Electrical Engineer by Jan. 7. See advertisement.

Working Electrician, Bridgend (Glam.) Urban District Council. Salary, £130 per annum. Applications by Jan. 5. See advertisement.

RAILWAY ELECTRIFICATION.

In this, the last issue for the year 1904, one naturally looks to see in which of its many branches electrical engineering has made the greatest strides in the year that is just closing. This looking back on the work of the year reminds us of the early days when it was possible to give a comprehensive review of the contracts actually completed by the few electrical firms which were then in existence. The rapid growth of the industry and the increase in the volume of business done renders any such review quite impossible at the present day. The striking feature, however, in the electrical engineering work carried out this year is the commencement of the electrification of our railways. The Lancashire and Yorkshire Railway Company have completed the conversion of their Liverpool to Southport and Crossens line, which involved some thirty miles of route, and the North-Eastern Railway Company have completed and opened for electrical working the suburban lines which connect Newcastle-on-Tyne with the seaside residential districts which have sprung up round Tynemouth and Whitley. In this case some thirty-five miles of route are involved, as some lines running westward to country districts have also been electrified. The even larger work of the electrification of the underground railways of London has been in full swing during the year, and the Metropolitan Railway Company have officially opened the line connecting Baker-street and Uxbridge for electric working. The Metropolitan District Railway Company have also run a number of trains on some of their outlying lines, and there is every prospect of the Inner Circle service being worked electrically in the spring of next year. While the work of the electrification of steam railways has now been started, the lines converted form but a small fraction of even the suburban lines which must eventually adopt electricity for motive power. The progress of electric traction on railways in this country has been slow, due, we believe, to the serious financial questions involved. Thus, the earlier electric lines, like the Liverpool Overhead Railway, opened early in 1893, or the pioneer tube railway of the City and South London Company, opened in 1890, were hampered by the excessive cost of construction per unit length, and also by the fact that they were isolated lines without through connection to other railway systems. In consequence of this, the financial returns have not given a sufficiently large dividend to the shareholders to make the public keen to finance other undertakings of a similar nature. The Central London Railway, with its better load factor, was more successful, and clearly proved, like its predecessors, that electricity is a more efficient agent for working rapid suburban lines. There is little doubt but that the competition of these earlier tube railways and of electric tramways is the chief reason why railway managers are beginning to electrify their suburban lines. In the case of the North-Eastern Railway the results obtained already show that traffic returns can be restored by electric traction to at least as high a level as before the tramway competition was commenced. Other railway managers now recognise that electrification is bound to come, and their attendance at the opening functions of electrified lines shows their keen interest in the subject. The work now being undertaken by the Great Western Railway Company and by the London, Brighton, and South Coast Railway Company is an indication that the interest does not stop at schemes on paper only. As regards the technical side of the conversion, it is now clearly proved that with electric trains higher acceleration and mean speeds can be obtained with the multiple-unit system more economically than by the older method of employing a locomotive, whether the same be steam or

Digitized by Google

electric. The details of this control of motors in various parts of the train from the driving compartment have yet, perhaps, to be considerably improved, but it is gratifying to know that three of our large firms are independently working on the subject, and they have each obtained success in practice, although their systems of control are radically different. This conduces to the survival of the fittest, and to the more economical electrification of other lines. While the progress in equipment for electrically driving heavy trains is satisfactory, there still remains with us the problem of conveying the current to the cars. All the time that the third rail was used on lines like the Liverpool Overhead or on the tube railways, in which the public have no access to the track, there was little to complain of as regards danger. This is far from the case when railways running through open country have exposed third rails for conveying the current at a voltage approaching six hundred. It is almost impossible to keep people from straying on to the track, and unfortunately with the unguarded rail a considerable number of fatal accidents have occurred. We understand that the London and Brighton Railway Company, acting on the advice of Mr. Philip Dawson, are going to try overhead conductors on their line near London, which is to be shortly equipped for electrical working. It seems to us that the ultimate solution of this problem is intimately connected with the new type of alternate-current railway motor, and that eventually overhead wires will be used with a much higher voltage on them. Increasing the voltage on the overhead wires will not materially increase the danger, as there are numerous satisfactory devices for rendering an overhead wire dead should a fracture occur. There is every sign that the year now before us will see great developments in the spread of electrification on our large railway systems, and we trust that the work will be more remunerative to contracting firms than other branches of the industry are at the present time.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE METRIC FALLACY.

SIR,—My attention has been drawn to a letter appearing in your issue of the 23rd inst. from Lord Belhaven, in which he states that it is obvious "if the proposal of the British Weights and Measures Association is carried out, the confusion would be as great, etc."

His lordship will perhaps be surprised to learn that this association has not yet made any proposal, though I am quite aware that some metricalists, for reasons of their own, have imputed to us a certain proposal which they have worked out in their own way, and made as big a muddle of it as they possibly could, and are now sending it forth as the prosposal of this association—a procedure which is about as correct as their statement that the metric system is "universal on the Continent except in a few nooks and corners."—Yours, etc., GEO. MOORES, Sec.,

British Weights and Measures Association.

London, S.W., Dec. 28, 1904.

SWITCHBOARD INSTRUMENTS, ETC.—Messrs. Cecil Hodges and Co., Balfour House, Finsbury-pavement, London, E.C., have recently published a price list, in which are included descriptions of their gravity and moving-coil instruments, recording instruments, horse-power meters, traction switches, circuit breakers, motor starters and regulators, porcelain switch fuses, distribution boards in cast-iron cases, house service fuse boxes, etc. The list is excellently printed on art paper, the illustrations being from wood blocks. We understand that Messrs. Hodges and Co. have a quantity of switchboard work in hand, including several large central station lighting and traction boards.

MANCHESTER LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

Presidential Address by C. D. Taite.

Before touching upon the subject of my address permit me to tender you my most sincere thanks for the honour you have done me in selecting me as chairman for the present session of the Manchester Local Section. This section is now, and has been for some time, by far the most important branch of the parent Institution, embracing as it does over 700 members of the various grades. The chairmanship of the section is, therefore, no empty honour, and while I am fully aware of my own deficiencies, you may rely upon my doing my utmost to follow in the steps of my predecessors, and to uphold—as they have done—the dignity of the chair. In this matter I am happy to know that I shall have the support of all members of the section.

As most of you are aware, a students' section was successfully inaugurated last session, and this immediately led to a large increase in the number of students belonging to the section; in fact, at one meeting of the Institution in London no fewer than 120 new Manchester students were elected. The students start the session with about 250 members, and an excellent syllabus has been arranged, upon which the Students' Committee are to be heartily congratulated. The ardour with which this new development has been taken up by the younger generation of electrical engineers augurs well for the future of this section, as the experience gained by expressing their views at the junior meetings will be of the greatest service to those concerned when they come to take part in these general meetings; the quality of our debate will soon be materially benefited.

I will now pass on to the subject with which I propose to deal principally to-night, as it is the branch of electrical work with which I am best acquainted—namely, electricity supply undertakings—and having had the privilege recently of a tour in America, under the auspices of our own Institution, and also the American Institute of Electrical Engineers, I propose to discuss a few points in which American practice differs from our own. Both in this country and in America the electricity supply business started in a very modest way, with small stations equipped with what would now be considered quite diminutive machines, the main point of difference in the practice of the two countries being that in America all wires and cables were run above ground, while almost from the earliest days both feeders and distributors in this country were laid underground with few exceptions. If we follow the development over here, we find that it has been slow but steady, the small stations being gradually enlarged, until in the big cities they became so unwieldy and so uneconomical that a new generating station on a comprehensive scale with big units became a necessity, the small stations being used as sub-stations for distribution purposes.

A fundamental difference due to legislative enactments in the methods of dealing with the problem of supplying electricity from central stations, was observed in the two countries from the commencement. In Britain, with the sole exceptions of London and Newcastle, competition in the supply business was prohibited, one provisional order being granted for each city, town, or district. In America, on the contrary, a town of the size of Chicago or Philadelphia would be divided up amongst quite a number of companies, totalling sometimes as many as 20, each operating on a comparatively small scale, and frequently adopting entirely different systems as regards voltage and type of current. The development was more rapid over there, on account largely of the absence of those vested interests which here one always finds opposed to any great change, and also because the overhead system of supply enabled cables to be run more easily and much more cheaply than in this country.

To the early success of supply undertaking in America is perhaps traceable a great divergence of practice in distributing electricity. I refer to the almost universal system of supplying current in the States at a pressure of 110 to 120 volts direct current for lighting and 230 volts for motors, as compared with our pressures of from 220 to

Digitized by Google

250 for lighting and 440 to 500 for power. It seems not improbable that when the higher-pressure lamp came along it was found it would be so expensive to change the arc lamps and motors that the psychological moment was allowed to pass without any alteration being made. Probably another reason was that no company operating in competition with other companies cared to make a change, which at that time would certainly have caused an increase in consumers' accounts, due to the low efficiency of the high-pressure incandescent lamps. Be that as it may, the Americans, with very few exceptions, did not make the change, and probably will never do so now. The result is that their distributing systems—so far as they are laid underground—are at the present time very much more expensive than ours, and where the supply necessitates sub-stations and transformation from high-tension three-phase to low-tension direct-current, sub-stations have to be much more frequent than over here. When the American engineers found their original sites becoming too small to meet the increasing demand, they recognised the fact that centralisation of large units under one roof would tend to economy, and there began in the various cities and towns the process of consolidation, with the result that at the present time one generally finds in each city one company only operating, this company being a consolidation of the many pioneer companies. By a series of developments, therefore, America has arrived at a point which our authorities foresaw from the first, and provided for by refusing to sanction more than one provisional order for a given area, and the evolution which has taken place over there seems to emphasise the fact that the competition that immediately arises between electricity and gas where light is concerned, and electricity and private plants where power supply is concerned, is in the nature of things so keen that to create competition between rival electricity undertakings in the same area is totally unnecessary, and not to the best interests of the community.

In England we are rapidly becoming converted to the advantages of the steam-turbine for driving our large units, particularly for alternating-current work. The manufacture of direct-current dynamos suitable for the high speeds at which turbines have to be run has not yet become general practice, though there are a fair number of successful turbo-driven direct-current generators in operation, but generally speaking they are of comparatively small size. It is now clear, however, that turbo-alternators can be satisfactorily designed and built for almost any power, and we shall shortly have running the power station of the underground railways in London, equipped with 10 5,500-kw. turbo-alternators, these machines being capable of carrying a load of 50 per cent. above that at which they are rated. The advantages of turbines have been enumerated so frequently that there is no need to tabulate them here. I would only call attention to two of them—namely, the great capacity they have for overloads, and, secondly, the saving in capital expenditure which their adoption renders possible. A 50 per cent. overload can be maintained permanently on a turbine with little loss of efficiency, the principal loss being generally in the reduced vacuum. It is, therefore, important when ordering turbo-driven plants to specify for ample margin in the generator, in order to take advantage of the overload capacity of the turbine, a feature likely to be of the utmost utility in central-station work.

With regard to the reduced capital expenditure required with turbo-driven plants, it is obvious that the plant itself costs much less than a slow-speed set of similar output, and owing to the reduced weight, the even turning moment, and the absence of all downward thrust, the foundations can be made much lighter. Again, a turbine plant—even of the vertical type—can be housed in a comparatively low building, and the floor space occupied is a minimum. On the other hand, in order to get the best results from a turbine, an ample water supply for condensing purposes is essential, and this to some extent restricts the choice of a suitable site. As regards coal consumption, the advocates of turbines and of reciprocating engines both claim the best results for the type which they favour, but I think that one will not be far wrong in stating that with regard to this feature there is little to choose between the two types, when both are working under suitable conditions. In America it did not appear that the turbine was making such rapid headway as in this country; one could not help being struck, for instance, by the very large number of slow-speed machines in course of construction going through the shops of the General Electric Company and the Westinghouse Company of America. On the other hand, at Boston and Chicago turbine stations are in course of construction, the machines being of the vertical type, and of 5,000 kw. capacity. In both these stations, but more especially in the case of the Chicago station, the division of the plant into units complete in themselves has been very thoroughly developed; thus not only was each set supplied with its individual condensing plant and hydraulic pump for the step bearing of the turbine, which is worked at 1,200lb. pressure per square inch, but there was by the side of each machine a boiler feed pump; thus the firemen had nothing to look after but their boilers and stokers. Each turbine, again, had its own range of boilers, which normally was kept quite distinct from the rest of the boilers, there being only a—comparatively speaking—small connecting pipe between two adjacent ranges for use in case of great emergency; there was also a common chimney for two ranges of boilers. The arrangement, in fact, was practically the same as in the Carville power station in Newcastle, the boiler-house being at right angles to the engine-room.

With regard to the control of these large units, the Americans have adopted everywhere—in some cases in a most elaborate manner—a complete system of oil-break motor-driven switches with electrical remote control; in some cases duplicate control boards have been provided, so arranged that while one remains in use the other cannot be operated. Duplicate 'bur bars appear to be universal, and they are so designed as to render it possible to sub-divide the feeders and sub-stations which they supply into distinct groups, each of which can be fed by a separate machine. The safety of the employés—as far as the handling of these large units is concerned—has been dealt with most thoroughly, and at the same time elaborate precautions have been taken to prevent breakdowns, and also to minimise their effect should a failure on any portion of the plant occur. The oil-break switches themselves are usually arranged in lock-up rooms provided for the purpose. The amount of capital expended on switchgear is very great, but figures giving the percentage of the capital expenditure under this heading were not forthcoming

With regard to the boiler-houses, Babcock and Wilcox boilers, sometimes with mechanical stokers and sometimes without, appeared to be the universal feature of American power-houses. It seemed strange to find that in a country where labour-saving devices are specially favoured, owing in some degree to the high rate of wages prevalent, the question of mechanical stokers *versus* hand firing has not yet been definitely settled. The Americans appear to be in the same state of doubt as to which system is the most economical in the long run, as we are in this country. When one hears of widely divergent results being obtained from mechanical stokers of the same make, and using similar fuel, one is driven to the conclusion that the personal factor of the fireman has a good deal to do with the results obtained, and in cases where inexperienced men have been employed, owing to the belief that a mechanical stoker only requires watching and oiling, good results can hardly be looked for. Experience seems to show that the quality of the labour required for the mechanical stoker is quite as high as for hand firing, but the quantity required is less. The fact is the burning of coal—if the best results are to be obtained—requires close attention and strict supervision, whatever be the means adopted for feeding the furnace, and steam users who neglect to take any account of the products of combustion can hardly look for the best results. In these days of automatic recorders there is plenty of choice as regards the necessary instruments for taking records of the flue gases, and when the apparatus is first connected to the flues, the small percentage of CO_2 gas indicated is frequently astonishing.

With regard to the staff employed in a generating station, all those who have visited the States must have been struck by the attention which is given to the personal

Digitized by Google

comfort of the staff, and also to the opportunity which is given to them to improve their technical knowledge by providing them with clubrooms, where they may meet and discuss matters of interest; these rooms are open, not only to the technical and office staff, but to every man employed by the company, however humble his position. Encouragement of this kind undoubtedly tends to make a man work more intelligently, and the statement that the men avail themselves largely of the facilities offered them to improve their knowledge seems to point to the fact that education in America has reached a higher standard than has yet been obtained in this country. This system of encouraging all grades of workmen to learn is a good one, and one which station engineers over here may with advantage take into consideration. In America there appears to be a much greater desire to gain knowledge than is the case in this country. Thus, when visiting Harvard University, we were informed that no less than 25 per cent. of the students earn their living while prosecuting their studies, and in the vacation it is no uncommon thing to find university men acting as drivers or conductors of tramcars, or doing other equally humble work. It certainly does appeal to engineers to find that a man is not looked upon with scorn at the highest seats of learning because he uses his hands to pay for the training of his brain. This enthusiasm for work is encouraged by employers, who have created a big demand for college-trained men. These men are paid from the day on which they start work, and their future promotion depends on their own ability and industry. A great deal has been written recently on the subject of the training of engineers. Personally, I feel that the facilities are available at the technical schools for young men to obtain a sound technical training provided that they attend the day classes for a three years' course. There is a necessity, however, for better organisation on the part of the educational authorities for obtaining appointments for their pupils when they have finished their course of technical instruction. It should not be a matter of great difficulty to make arrangements with local manufacturers whereby the latter would undertake to reserve a certain number of appointments annually for suitable scholars from the technical schools if they were forthcoming. In this manner technical training would receive great encouragement, and eventually the employers would certainly reap the benefit. One cannot expect men to give up three years of their life for technical training if at the end of that time there is no prospect of an appointment.

Turning, now, from central-station practice to the question of transmission and distribution of electricity, we find in America conditions which do not exist in this country. Over here, with few exceptions, there is no great difficulty in finding a suitable site for a generating station in any town where a supply is required; to that extent the conditions are the same in America, but there is this great difference that in many parts of the country, water power remote from any large centres of population is available, and is utilised for generating electricity; the power so generated has to be transmitted to the towns, with the result that overhead systems working at what we should consider excessively high pressures are quite widely used. The longest transmission scheme which was visited by the Institution of Electrical Engineers on the occasion of the recent tour was that from Shawinigan, on the St. Maurice River, in the Province of Quebec, to Montreal, a distance of about 90 miles. Power is transmitted on this system at a pressure of 50,000 volts, the current being three-phase at 30 periods, and the conductors being of aluminium. The line runs the whole distance alongside the railway, which is convenient, as the country is quite new, and transport difficulties would otherwise arise. This transmission scheme is typical of many other cases, with the result that three-phase working from the transmission point of view was developed much earlier than was the case in this country, where the necessity for high-tension transmission did not arise so soon. At the same time, it is noteworthy that while the three-phase transmission schemes have been perfected, the distribution schemes are almost invariably on the original system of three-wire, direct-current at 110 to 120 volts between the neutral and each of the outers, with a certain amount of alternating current for the scattered suburbs. The question of speed regulation of motors has undoubtedly had a great deal to do with the general adoption of direct current, while with regard to the low supply pressure referred to previously, it was stated that not only did expense stand in the way of any change to a higher pressure, but in the interests of consumers themselves, the lower pressure was preferable owing to the higher efficiency claimed for the lamps. The latter argument was undoubtedly one of considerable force in this country years ago, when the first changes to the higher pressure were being made, but at the present day there is little to choose in efficiency between lamps of 110 and 220 volts; and the saving in capital expenditure, not only on the cable system, but also in the houses of consumers, makes the higher pressure undoubtedly the most economical for both supplier and consumer. With regard to lamp pressures, the Edison companies control a large number of stations, and arrange matters so that the standard pressure in the various towns differs slightly. This is done in order to utilise to the fullest extent the lamps turned out by the lampmakers, the specification and standardisation of these lamps for the various pressures being very rigid.

Referring to the principle involved in the consideration of overhead *v.* underground conductors, where overhead systems are carried to excess, as has been the case in some of the American cities, particularly in Pittsburg and Montreal, the effect is most disfiguring. On the other hand, there is a good deal to be said for overhead conductors for scattered areas, whether they be suburbs of a large city or only a country district. In such areas the cost of cable per consumer frequently runs out to a very high figure, which could be much reduced if overhead distribution met with favour and could be adopted. Electricity is in much more general use in America for all purposes than is the case in this country, in spite of the fact that in the large cities, at any rate, the price charged is considerably higher than in England. Thus in Boston, where they have a lamp connection of 500,000 16-c.p. lamps and 24,000 h.p. in arcs and motors, the normal flat rate for lighting is 10d. per unit, subject to discounts according to current consumption. A small power consumer pays 3d. per unit, and the lowest figure quoted to any party is 1d. On these prices we were informed that private plants were rapidly being given up. At Chicago the price was on the maximum demand system, with Wright indicators, the tariff being for lighting 10d. for 30 hours' use per month of the maximum demand and 5d. for all current used in excess; similarly for power the price charged was 5d. and 2½d. Similar prices were charged in most of the other large cities visited. Wattmeters are universally used for registering the current, as compared with our system of ampere-hour meters.

With regard to output, the New York Edison Company, with a population in its area of about 2,000,000, has a maximum load of 50,600 kw. for lighting and power, with an annual output of 131,000,000 kilowatt-hours, which is a greater output than all our London companies and municipalities combined can muster. Montreal is an exceptional case, but it is so interesting that its position is worth recording. It has a population of 350,000 and 10,500 customers, compared with the 5,171 consumers of Manchester with a population nearly twice as large. The annual consumption, which includes power for the tramway service, is no less than 85,000,000 kilowatt-hours, and the company which supplies the current is the fortunate possessor of a 75 per cent. load factor. Amongst the consumers at Montreal is a 3,000-h.p. cotton mill, which is driven throughout by electricity, paid for at the rate of ½d. per kilowatt-hour. The mill has arranged its hours of work so that in certain winter months no current is taken between the hours of 4 and 7 p.m., hence the low rate of charge. This alteration has only necessitated a reduction of the average weekly working hours from 56 to 54. We were informed that the output from this mill had increased 40 per cent. since the conversion to electric driving, owing to the greater flexibility of the system and improved machinery as compared with steam driving; that 40 per cent. represented greatly increased profits, the costs, exclusive of the raw material, being practically constant. Other consumers in Montreal are given the benefit of a

Digitized by Google

reduced tariff in cases where they undertake not to use their supply in winter months between the hours mentioned above. This system has been adopted to some extent in this country, notably at Brighton, but it is evident that if we are to bring up our load factors to anything like the same figure as at Montreal we must, under certain conditions, reduce our price much below anything quoted at present. There is no doubt but that it would pay many of our North Country stations handsomely to supply current between certain hours at ½d. per unit, and it would not require much modification of mill hours to accommodate themselves to a power supply, which would only be shut off in the months of November, December, January, and February, from 4 to 7 p.m. Such a striking example of what can be done in the way of obtaining a good load factor is well worth the consideration of all those who have to deal with the supply of electricity in this country, it being remembered that improvement in the load factor, even if it be obtained at a low margin of profit, must eventually be the means of a reduction in price to the general body of consumers.

Municipalities in America, at any rate in the larger cities, and to a considerable extent in the smaller ones, have not cared to take up the position of public suppliers of electricity, as has been done in this country; they have instead given franchises, usually for 50 years or thereabouts, to companies, who appear to be organising their business on a very sound basis. The companies frequently have a wiring department, and in some of the cities this department nearly monopolises the wiring business of the city. The lamp question has been solved in America by giving the consumer free lamps. The Edison companies, of which there are a great number, have large local organisations for dealing with this part of their business. Every consumer starts his installation with lamps furnished by the supply company, nominally on loan; he may have these lamps changed as often as he thinks fit, and in case of the theatres, where coloured lamps are frequently required, they are often changed weekly without any charge outside the cost of carriage. All lamps prior to being sent out are tested for candle-power and consumption, the limit for a 16-c.p. lamp being in the region of 14·5 c.p., and the consumption 3·2 watts per candle-power. All lamps are marked with their voltage, candle-power, and with the name of the supply company. When lamps are brought in, should they give less than 14·5 c.p. at normal voltage, they are, if sufficiently good, put aside for colouring for shop signs and theatrical purposes; otherwise, if too much blackened, they are destroyed. The life of the lamp is only reckoned as about 500 hours; their price is 7½d. We were told that the system of giving lamps free added about ½d. per unit to the price of current, but that figure seems to be rather under the mark, the total cost of the system being between ⅓d. and ½d. Be that as it may, the effect of the system on the incandescent lighting is very marked. Lamps in the shop windows always look bright and give a good light, and blackened lamps are as rare in America as they are common in this country. It is difficult, however, for engineers in this country to recommend their directors or committees to adopt exactly the same system here. The companies in America, by doing the bulk of the wiring themselves, have not to consider the effect of giving free lamps on the position of the wiring contractor. In England, on the other hand, it is very rare to find a company or a corporation doing the wiring of the district. This is in the hands of the contractors, who calculate to make a steady income out of the sale of lamps, and there would naturally be a great outcry on the part of these gentlemen if the free-lamp system, as adopted in America, were introduced on a large scale into this country. On the other hand, some such system seems to be the only way of ensuring that the consumers get a thoroughly satisfactory light with a minimum expenditure of current; and if the manufacturers were aware that all their lamps would be tested by an independent authority, and would be returned if below a certain standard of efficiency, it would make them much more careful as regards the class of lamp they sent out. The American system, however, has its drawbacks. Thus the consumer, being assured of a free supply of incandescent lamps, has very little encouragement to try any new type of lamp, such as the Nernst; and it is a fact that in America so small is the demand for Nernst lamps, where direct current is supplied, that a design suitable for direct current has not yet been put upon the market. The lamp is in the hands of the Westinghouse Company, and is used on alternating-current circuits only.

Generally speaking, the average American seems to have a much better appreciation of electricity for all purposes than the average Briton; he has appreciated its virtues, and has adopted it accordingly; he also appears to have made up his mind that it is profitable to him to buy his supply from the public mains at a price giving a reasonable margin of profit to the company, than it is to worry about a private installation; his money can be invested to better account in plant suitable for his own processes of manufacture; and he prefers to put his whole energy into his own business, rather than be troubled with the details of a private plant. Many of our smaller manufacturers in England might well learn a lesson from the American in this matter, though it may be thought that I speak with some bias; nevertheless, I assert unhesitatingly that many works which put down separate installations would find the convenience of a public supply which is always available more than outweigh the saving which they frequently only think they obtain by generating their electricity for themselves. It is a remarkable fact, and one much commented on in America, that while the American generating costs are as a whole no greater than similar costs in England, being, in fact, considerably lower than are obtained, generally speaking, by London stations, yet the selling price of current in America has to be considerably higher than the price in England in order to obtain the same return on the capital invested. It was a matter of great difficulty to obtain detail costs, including management charges, of American supply undertakings, but it seems pretty clear that the cost of the various consolidations that have taken place has been very appreciable. To begin with, the original companies which formed the consolidated company had frequently adopted different systems of generation and supply; thus some would be alternating with different periodicities, while there would also be considerable variation in the supply pressures. To bring these various systems on to a common basis has been an expensive matter, and it is well known also that consolidations of this description rarely take place without the creation of a large amount of paper capital. It has been recently pointed out by Mr. Merz in his admirable paper on "Power Station Design," that an increase of £1 per kilowatt on capital expenditure has a greater effect on the running costs than has a reduction of the coal bill by 6 per cent. where the price of coal does not exceed 6s. per ton. In America the coal bill is low, due to the use of large and economical units, but the capital expenditure per kilowatt installed is high, owing to the charges which have had to be made in assimilating the systems of the various companies, and in effecting the consolidation. From the companies' point of view the position is a satisfactory one, as a monopoly has been established, but from the point of view of the consumer it will be some years before he feels any financial benefit from the process of evolution which has taken place. This experience emphasises in a marked degree the necessity for careful finance with regard to capital expenditure.

The supply of electricity business is different from most others with which we are familiar, owing to the preponderating effect of capital expenditure as compared with running costs upon the selling price, and it behoves us, therefore, to do our utmost to prevent the capital of the undertakings with which we are concerned being unnecessarily inflated. As plant becomes obsolete the capital it represents should be written down out of revenue, and although this may mean a temporary loss of apparent profit, the undertaking will soon reap the benefit by the increased business which the reduced charges will bring in; it cannot be driven home too strongly that a heavy capital expenditure per kilowatt installed is bound, under ordinary conditions, to necessitate a high tariff, with a correspondingly restricted business. To undertakings, whether worked by companies or municipalities, which intend to cultivate a power load, this is a matter of great importance,

Digitized by Google

and I am of opinion, therefore, that where current has to be transmitted to scattered areas, overhead wires should be as far as possible adopted. Where it is necessary, as in the case of the power companies, to convey electricity in many directions over huge areas, it would seem that overhead conductors are essential if the companies are to attain financial success. That it is important to all of us in whatever branch of the profession we are employed that these power companies should be successful is, I think, self-evident. Any development in the use of power in their areas cannot but stimulate the demand for electricity throughout the country generally.

We shall all watch, therefore, with the greatest interest—not unmixed with anxiety—the progress made by the pioneer stations which these companies are equipping. Apart from the supply of power to mines and factories, they should have a large sphere of usefulness in supplying current, not only to those towns which have not generating stations of their own, but also to those which have. In many cases I think it will be found to be to the best interests of those concerned to purchase current from outside in preference to carrying out expensive extensions to existing works, provided that the prices quoted are as reasonable as one has been led to suppose they will be. In any case, municipalities and others will do well before embarking on extensive schemes of expansion to enquire what the power companies are prepared to do, and to compare the terms quoted with their own costs, not forgetting the effect of the proposed capital expenditure on the selling price.

In conclusion, I am glad to have an opportunity of placing on record my great appreciation of the facilities afforded us by the American Institute of Electrical Engineers, on the occasion of the recent tour, for fully investigating the most recent practice in the generation and distribution of electrical energy in their country. The programmes in the various towns visited were organised in a manner beyond all praise, and everywhere we were received with unbounded hospitality. Under such favourable conditions a successful tour was assured, and those who were privileged to take part in it will not soon forget the elaborate preparations made to ensure their comfort. The compilation of the electrical handbooks alone, containing as they do a history of each city and neighbourhood visited, together with an account from the earliest days of the various electrical supply undertakings and manufacturing companies connected therewith, was a work of very great magnitude, and one which was thoroughly appreciated by the fortunate recipients. They form a complete work of reference of the progress of electrical engineering in America, and they will always be treasured by the whole party as a permanent memento of the tour.

FORTHCOMING EVENTS.

Jan. 5.—A general meeting of the Röntgen Society will be held at 8.15 p.m., when Mr. C. E. S. Phillips will give a description of an automatic vacuum pump, which will be followed by an exhibition of a method by which strongly-adherent films of aluminium may be applied to glass; and "A Note on the Colouration of Glass by Radium Radiation."

Jan. 10 and 11.—At the Institution of Civil Engineers, Sir W. H. White will deliver an address, entitled "The Recent Visit to the United States and Canada."

Jan. 13.—A lecture, entitled "Theory of Electricity and Magnetism," will be delivered by Mr. J. Swinburne to the students of the Institution of Civil Engineers.

Jan. 27.—The following papers will be read at the Physical Society: "Action of a Magnetic Field on the Discharge through a Gas," by Dr. R. S. Willows; "Action of Radium on the Electric Spark," by Dr. Willows and Mr. J. Peck; "The Slow Stretch in India-rubber, Glass, and Metal Wires when subjected to a Constant Pull," by Mr. J. Phillips; "Determination of Young's Modulus for Glass," by Mr. C. A. Bell; and "Some Methods for Studying the Viscosity of Solids," by Dr. Boris Weinberg.

Jan. 5.—Rugby Engineering Society. A paper will be read on "Patternmaking," by Mr. R. Watson.

Jan. 12.—At the Institution of Electrical Engineers, resumed discussion on Mr. Adams's paper, "The Combination of Dust Destructors and Electricity Works Economically Considered," and, time permitting, Messrs. Booth and Kershaw will present a paper on "Fuel Economy in Generating Stations."

FARADAY SOCIETY.

The tenth ordinary meeting of the Faraday Society was held on Monday, Dec. 19, 1904, at the Institution of Electrical Engineers, Mr. J. Swinburne, vice-president, occupying the chair.

M. ADOLPHE MINET communicated Part II. of his paper on "The Electric Furnace: its Origin, Transformations, and Applications," which was kindly read in abstract by Mr. R. S. Hutton. In the first and introductory part of his paper, which was read before the society on June 9 last, M. Minet showed that the historical development of the electric furnace falls into the three following periods: (1) laboratory furnaces, 1808 to 1886; (2) industrial furnaces, 1886 to 1890; (3) development of industrial applications from 1890 to the present day. The present instalment, after some preliminary general remarks on the E.M.F., current densities, and yields, with arc furnaces and resistance furnaces respectively, proceeds to deal in detail with the evolution of the furnace during the first period. The subject is subdivided as follows: (*a*) original furnaces—namely, Davy's arc, Pepys's resistance furnace for the cementation of iron, and Davy's and Napier's cathode furnace; (*b*) electrolysis at high temperatures—the production of aluminium and its alloys, and the alkali and alkaline earth metals; (*c*) miscellaneous furnaces, of which the most important are the early Despretz and Pichon furnaces, Berthelot's electric "egg" for the synthesis of acetylene, Siemens's and Huntington's well-known steel and other furnaces, the Louis Clerc furnace, interesting as the progenitor of the famous Moissan type, and Borcher's resistance furnace. The paper, which is illustrated with diagrams of the principal furnaces alluded to in the text, closes with a bibliography covering the period dealt with. A final instalment will discuss the furnaces of the second and third periods.

Mr. W. B. CLARKE referred to the importance and difficulty of making temperature determinations of electric furnace processes, and expressed the hope that M. Minet would deal with that question in Part III. of his paper.

Mr. L. GASTA handed round some "siloxicon"—one of the newest products of the electric furnace—and described its properties.

Mr. E. KILBURN SCOTT (communicated) described some of his experiences in the early days of the manufacture of calcium carbide.

The CHAIRMAN described a novel type of furnace that he had once hit upon by accident, and which he thought might turn out to be useful. He was sending a current through fused barium chloride, and the temperature having been allowed to get too high the cast-iron crucible melted and formed a fused mass that was kept together by an outer skin of solidified chloride. This suggested the use of a neutral substance like barium chloride for heating to a very high temperature alloys or metals which it was desired not to contaminate with impurities.

Dr. F. MOLLWO PERKIN read a paper by himself and Mr. W. C PREBBLE on the "Electrolytic Analysis of Cobalt and Nickel."

Cobalt.—The aim of the experiments was to obtain bright deposits of the metal that should be quantitatively accurate. Various reducing agents were first of all employed, but only with sodium hypophosphite were brilliant deposits obtained, and then phosphorus was found to be present. Salts of the various organic acids were next tried, but only ammonium oxalate and tartrate gave satisfactory results, the latter having the better appearance. Traces of carbon, however, were deposited with the metal. Ammoniacal solutions of ammonium borate were also tried. The most satisfactory results were obtained with a solution containing an alkali phosphate and a little phosphoric acid, the latter to prevent the precipitation of the double sodium cobalt phosphate. To remove a brown anodic deposit which forms, the addition of a little hydroxylamine is recommended. By this method the whole of the metal can be thrown out in from 3 to 3½ hours.

Nickel.—Similar solutions were tried for nickel deposition. In this case splendid results were obtained with the borate solution, while the phosphate solution, which gave

Digitized by Google

such good figures in the case of cobalt, was not at all satisfactory. The authors have not yet succeeded in devising an accurate electrolytic method for the separation of nickel of cobalt, and they find that the methods given in books are unreliable.

Dr. O. J. STEINHART discussed the problem of the separation of the metals. The present method is based on the fact that cobalt is more easily oxidised by chlorine than is nickel. He also referred to the possible industrial bearing of the work of the authors in connection with nickel extraction.

Dr. L. DOBBIN, in a written communication, drew attention to the work of Marshall on the same subject. In the case of cobalt, he merely added a little nitrate to the ordinary double sulphate solution.

Dr. PERKIN said that the presence of nitrate rendered deposition very slow.

Mr. F. GELSTHARP presented two short papers entitled "The Electrolytic Preparation of Tin Paste" and "Note on the Electrolytic Recovery of Tin" respectively, which were read by the Secretary. The author first describes briefly the original Indian mode of making tin paste—which is used for the production of metallic paper and other ornamental purposes—and the chemical process as generally carried out. The latter is troublesome on account of fumes, and some of the tin is precipitated as bright crystals, which are useless for this purpose. Moreover, the electrolytic process is less costly, in spite of the low current efficiency (50 per cent.), and can be worked continuously. The process consists in dissolving anodes of tin, roughly cast from commercial ingots, in dilute hydrochloric acid, and depositing the metal in the form of sponge on cathodes of block tin or tinned iron. The current density at the cathode is 270 amperes per square metre. The electrolyte is kept in a state of rapid circulation. The deposited sponge is allowed to grow to a thickness of about an inch and is then scraped off the cathodes. It then floats to the top of the bath and is scooped away. To produce 20cwt. of paste a week requires a generator giving 1,500 amperes at eight to ten volts. Mr. Gelstharp's second note describes an experiment that has some bearing on the conditions necessary for electrolytically stripping tin plate. A current was sent through an electrolyte of pure caustic soda at a temperature of 80deg. C. by means of an anode and cathode of tin plate. The voltage was 3½, but a current of only one third of an ampere passed through the cell; there was very little gassing, and the tin did not strip from the anode, but became coated with a light-brownish adherent deposit. the author considers this to be an oxide of tin, for on reversing the current for an instant and then reversing again, a current of 1½ amperes at one volt passed freely, and the tin was effectively dissolved, due to the reduction of the oxide film to metal by the hydrogen evolved at the moment of reversal. The deposited tin generates hydrogen in water. The author considers that, besides containing an alloy of tin and hydrogen, tin paste deposited from an alkali solution also contains sodium. Agitation of the cathode is of great importance in tin recovery. A quick succession of shocks by reducing polarisation reduces the consumption of energy by 30 to 40 per cent. Finally, the acid and alkali processes for tin recovery are compared. The former is the more suitable for making tin paste, and the latter for tin recovery from scrap.

Mr. W. C. PREBBLE thought an endless band would be a less crude method of removing the paste than that given by the author. Regarding the presence of arsenic, which was hurtful here, it was curious that in the case of zinc this actually causes a spongy deposit to form.

Dr. O. J. STEINHART gave a few particulars of an electrolytic detinning process that was now successfully treating in London seven or eight thousand tons of scrap per annum. A great difficulty found in practice was to dry the tin sponge without its firing.

Dr. T. C. CAIN did not think it probable that sodium was deposited with the tin.

Mr. H. SAYER asked what percentage of the tin was recovered. An objection to an alkali process was that it would not remove the tin from the alloy at the surface junction of the two metals.

Mr. A. C. BAWTREE sent in a written communication describing an electrolytic method for making tin powder that he had worked out some years ago. His solution contained 0·5 per cent. $Sn Cl_2$ and 0·33 per cent. $Sn Cl_4$, and was worked cold with an E.M.F. of 2·32 volts. This solution successfully overcame the difficulty of crystalline deposits.

Mr. H. S. COLEMAN also communicated some of his own experiences in tin deposition. He had worked under conditions similar to those described by Mr. Gelstharp. He found, however, that if the bath were worked between 50 deg C. and 60deg. C., no difficulty was experienced in starting the current, and the scrap was stripped clean in 20 minutes.

TRADE NOTICES AND NOVELTIES.

Catalogues, etc.

HART ACCUMULATOR CO.—This company, of Marshgate-lane, Stratford, London, E., are issuing a serviceable blotting-pad for 1905.

ELECTRICAL POWER STORAGE COMPANY, LIMITED, 4, Great Winchester-street, London.—The above company have issued as usual their useful combined blotter, pad, and calendar illustrative of their E.P.S. storage batteries, which are now used in 200 central stations and over 10,000 private installations in the United Kingdom, and which we learn have obtained the highest awards wherever exhibited.

XMAS CARD.—Mr. F. Hope Jones sends us a Xmas card in the shape of snapshot taken in September of the Electricity Building at St. Louis, where the "Synchronome" system was awarded a gold medal.

DRY BATTERIES.—A leaflet which we have received from Messrs. Krupka and Jacoby, 61-62, Watling-street, London, E.C., gives some particulars of Dr. Lessing's dry battery, seven sizes of which are listed. It is claimed that these batteries possess very high efficiency, excellent insulation, low internal resistance, reliable recuperative power, and neither leak nor burst open.

TANGENTIAL WATERWHEELS.—The Abner Doble Company, of San Francisco, California, U.S.A., have sent us an illustrated pamphlet describing the tangential waterwheels which they make to operate under high heads of water.

ELECTRIC LIGHT ACCESSORIES, ETC.—The Sun Electrical Company, Limited, 118 and 120, Charing Cross-road, London, are now issuing Section X of their 1905 catalogue. This section deals with electric light accessories, switches, switchboards, distribution boards, cables, instruments, incandescent lamps, Simplex conduit, etc. It runs into some 130 pages, and is well illustrated.

GAS AND OIL ENGINES.—The latest illustrated catalogue issued by the Acme Engine Company, Limited, Budhill-avenue, Shettleston, Glasgow, contains a great deal of information about gas-engines, oil-engines, and suction gas producers of their manufacture, besides some useful hints to users of gas-engines. On p. 31 there is illustrated a 44-b.h.p. Acme gas-engine, combined with a 60-b.h.p. suction gas producer, the whole making an exceedingly compact plant.

PERSONAL.

The resignation of Mr. E. Moxon, mains superintendent, has been accepted with regret, and Mr. J. W. Turner has been appointed chief electrical assistant at Huddersfield.

Mr. Heron, the late electrical engineer for Elland, who has resigned his position as a protest against the dismissal of his assistant (Mr. Barton) is beginning business in Huddersfield as a consulting engineer. Mr. Barton has received an appointment as chief electrical engineer under the Horsham Council in Sussex.

The Acton District Council have confirmed the appointment of Mr. James Harry Chick, of Horsham, as senior charge engineer in the electricity department at a salary of £130 per annum.

A presentation was recently made to Mr. J. J. Lightfoot by the staff of the electricity department of the Woolwich Borough Council before he has obtained his present appointment with the County of London Electric Supply Company, Limited. The present took the form of a gold albert. Mr. Lightfoot has the good wishes of his former colleagues for his future success.

One hundred and forty-seven applications from all parts of the kingdom were received for the position of electrical engineer to Leigh Corporation. The Tramways and Electricity Committee have decided to recommend the appointment of Mr. A. T. Smith, of Bury. The salary is £250 per annum, rising by annual increments of £25 to £350. Mr. D. M. Kinghorn, the present engineer, has been appointed electrical engineer of Southwark at a salary of £350 per annum.

Digitized by Google

LEGAL INTELLIGENCE.

A TRAMCAR NOT A HACKNEY CARRIAGE.

The Lord Chief Justice, Mr. Justice Kennedy, and Mr. Justice Ridley heard an appeal by the Yorkshire (Woollen District) Electric Tramways (Limited) against a decision of the justices of Dewsbury, who had convicted and fined them 2s. 6d. The appellants were a light railway company, formed under provisional orders in accordance with the Light Railways Act of 1896; and the respondent, Mr. Hiram Ellis, the town clerk of Dewsbury, summoned them for allowing one of their cars to ply for hire in the borough without a license, his contention being that under the Towns Police Clauses Act of 1847 the vehicle must be regarded as a hackney carriage. The magistrates had upheld this contention, and this appeal was against this decision.

Mr. Danckwerts, K.C., for the appellants, said the decision that a carriage run upon a light railway was a hackney carriage carried with it the absurdity that a light railway must get a license from every local authority through which the line ran, and each local authority would have the discretion of saying how many of these carriages there must be.

The Court allowed the appeal, with costs, and quashed the conviction.

The **Lord Chief Justice** said they could not come to the conclusion that that which was in substance a railway was to be subject to the provisions of the Towns Police Clauses Act in regard to the licensing of hackney carriages. The absurdity of the thing was too great. The appeal, therefore, must succeed.

ACTION AGAINST THE LONDON UNITED TRAMWAYS COMPANY.

An action came before Mr. Justice Ridley and a jury in which Alfred John Simpson and his wife claimed damages for injuries alleged to have been sustained through the negligence of the servants of the London United Tramways.

The plaintiffs were driving a pony and trap along the Chiswick High-road in the direction of Kew, and when opposite Linden-gardens, Mr. Simpson pulled on to the tramlines to pass another van going in the same direction, when the wheel of the trap skidded in the tramlines, and threw the horse and cart across the other set of metals. A tramcar which was proceeding towards Hammersmith was then 20 or 25 yards distant, but the driver, according to the plaintiffs' account, made no effort to stop his car, and ran into the trap, throwing out Mr. and Mrs. Simpson, both of whom sustained injury, the trap being smashed beyond repair.

The defence was that the tramway lines were in a perfect condition, only having been repaired the week prior to the accident, which was due to the pony either shying or being driven across the up metals right in front of the oncoming car.

His Lordship, in summing up, stated that the real question for the jury to consider was, Had the driver of the car time to avoid the accident?

The jury returned a verdict for the defendants, with costs.

COMPANIES' MEETINGS AND REPORTS.

BRITISH ELECTRIC TRACTION.

The interim report of this Company states that the directors have not undertaken new obligations of any magnitude, and the policy of restricting capital commitments as much as possible for the present has enabled them to reduce considerably the administration expenses, whilst some promising schemes are kept in reserve to be dealt with when conditions are more favourable. There has been an increase in the aggregate traffic receipts of the associated companies, although, owing to the general depression in trade which has prevailed during the year, the increase has not been so large as was anticipated. It is hoped, however, that with the expected revival in trade there will be a further improvement in traffic receipts and in the income from the Company's investments, which last year yielded £136,230. The award of the umpire in the matter of the sale of the undertaking of the Poole and District Electric Traction Company, Limited, to the Bournemouth Corporation has not yet been made, but may be expected shortly. This has since been announced, and is referred to in our "Traction" notes. The directors have declared the usual interim dividend at the rate of 6 per cent. per annum upon the ordinary shares for the six months to Sept. 30 last.

BLACKPOOL ELECTRIC TRAMWAYS (SOUTH).

A special meeting of debenture holders of this Company have had laid before them a scheme for writing off 20 per cent. of the debenture stock, 3½ per cent. instead of 5 per cent. being paid on the balance for the next 11 years. At the end of that period, if the Company achieved the success anticipated, the written off debentures were to be reinstated, and the difference between 3½ per cent. and 5 per cent. paid on the whole stock. The debenture holders appointed Messrs. Percy Musgrave (Bolton), A. M. Sing (Liverpool), and Joseph Wilson (Liverpool) to associate with the trustees (Mr. Harmood Banner and Alderman Joseph Heap) as a committee "to consult as to the best course to be taken in the interest of the stockholders." This committee was empowered to raise £10,000 to meet the immediate requirements of the Company and to finish the construction of the tramway, and to appoint managers of the undertaking. The consideration of the financial scheme was postponed to another meeting of the stockholders, to be held on a date to be fixed by the trustees.

FLYING MACHINES.

Under the winding-up order made against the Sir Hiram Maxim Electrical and Engineering Company, Limited, meetings of creditors and shareholders have been held at the Holborn Restaurant before Mr. A. S. Cully, assistant receiver.

Proofs for £10,611 have been lodged by 167 creditors, but the statement of affairs has not yet been completed. The unsecured debts are stated to amount to £29,804, in addition to loans on debenture bonds, £20,000, and interest thereon £305, while the assets are valued at £57,000, showing a surplus, as regards creditors, of about £7,000. The Company was formed in May, 1899, as the Maxim Electrical and Engineering Export Company, Limited, with a nominal capital of £100,000. Its object was to acquire the sole rights for the sale in Australasia, Africa, and Asia of all articles to be manufactured by the Hiram Maxim Electrical Company, Limited, and by J. F. Pease and Co., Limited, of Middlesbrough-on-Tees. In February, 1901, the name was changed to the Hiram Maxim Electrical and Engineering Company, Limited, the capital being increased to £175,000, and in September, 1903, a further increase of £15,000 was made, making the total capital £190,000. The present issued capital was £170,399. Mr. Alfred Hardie had acted as managing director since January last. In the following March the Company acquired from Sir Hiram Maxim his patent rights relating to captive flying machines, and another company was afterwards formed, with a nominal capital of £30,000, and acquired those rights for £20,000, payable in shares. Several thousand of the Flying Machine Company's shares had been sold at par. A reconstruction scheme is contemplated, so it is proposed that a liquidator other than the official receiver shall be appointed. Mr. Alfred Hardie and Mr. A. F. Whinney have been nominated for this office, and the appointment will be settled by the Court.

Sir Hiram Maxim said he had put a great deal of money into the Company, and had not sold a single share. Owing to the state of his health he had been out of England during the greater part of the Company's existence, and had, therefore, but little knowledge of its affairs. He had derived no pecuniary benefit from his association with it.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Oporto.—The Municipal Authorities require tenders for lease o their electric tramways. Tenders by March 15.

Bucharest.—Tenders are required by Jan. 5 at the offices of the Roumanian State Railway, Bucharest, for the supply of a 20-h.p. motor-wagon.

Berne.—M. G. Anselmier, of Berne, has obtained authority to construct and work three electric funicular railways in that city; the cost of the construction is estimated at £16,000.

Caen (France).—The Prefect requires tenders for concession of a tramway from Eyes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1, 1905.

Completion of Works.—A local authority in possession of powers for the electric lighting of its area is open to negotiate with suitable persons for the execution and completion of the works. See advertisement.

La Paz (Bolivia).—The Municipality require tenders for the electric lighting of the town for 12 years. There is an old central station and water power of 150 h.p. to 200 h.p., which is sufficient for the number of lamps required. Tenders by Jan. 15, 1905.

Port Elizabeth.—Messrs. Davis and Soper, 54, St. Mary-axe, E.C., agents of the Municipal Corporation of Port Elizabeth, South Africa, invite tenders for various works in connection with the Corporation electricity supply undertaking Tenders by Jan. 16, 1905.

Pudsey.—The Corporation invite tenders for underground electric mains, switchboard, etc. Specifications, etc., may be obtained on application to Messrs. Shepherd and Watney, consulting engineers, Greek-street-chambers, Leeds, Tenders to the Town Clerk by Jan. 20.

London, N.—The Metropolitan Asylums Board invite tenders for installation of fire-alarms at Northern Hospital, Winchmore Hill, N., in accordance with plan and specification prepared by Mr. W. T. Hatch, M.I.C.E., M.I.M.E., engineer-in-chief. Tenders by 10 a.m. on Jan. 24.

Swindon.—The Corporation invite tenders for the supply and erection of one 30ft. by 8ft. Lancashire boiler with down-take superheater, steam, exhaust, and feed piping, etc. Tenders to be delivered before 10 a.m. on Tuesday, Jan. 24, 1905, to Mr. Robt. Hilton, town clerk. See advertisement.

Erith.—The Urban District Council invite tenders for overhead line equipment, poles, etc.; underground feeder cables, boxes, etc.; rotary converters, transformers, and motor-booster; and main high and low tension switchboards, cable connections, etc. Tenders by Jan. 9. See advertisement in last issue.

Hull.—The Public Libraries Committee invite tenders for the necessary electric light installation and fittings required at the Carnegie Library, West Park, Anlaby-road. Specifications may be obtained at the office of Mr. Joseph H. Hirst, city architect, Town Hall, Hull. Tenders are to be addressed to the Chairman of the Libraries Committee, and delivered at the Town Clerk's Office, Hull, before 10 a.m. on Jan. 2.

Digitized by Google

Johannesburg.—The Council invite tenders for Vignoles rails, fishplates, angle steel guard-rails, bolts, nuts, coach screws, and dog-spikes. General conditions, specifications, and forms of tender may be seen at the offices of the Council's consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W., and may be obtained on payment of five guineas. Tenders by Jan. 26. See advertisement in last issue.

South London Electric Supply Corporation.—The Directors invite tenders for the construction, supply, and erection at their works at Bengeworth-road, Loughborough Junction, S.E., of one 750-kw. steam alternator with pipe connections and sundry ironwork. Sealed tenders must be forwarded to the secretary of the company, Mr. H. H. Boyer, Bengeworth-road, Loughborough Junction, S.E., before noon on Jan. 16. See advertisement in last issue.

Shanghai.—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Peok and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

Plasencia.—Tenders are required for the concession for 10 years of the lighting by electricity of the town. Adjudication of tenders will take place on Jan. 28, and tenderers, if not appearing in person, must be represented by a duly authorised agent. The conditions of concession are set out in the notice in the *Gaceta*, which may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between the hours of 10 a.m. and 5 p.m. (Saturdays, 10 a.m. to 1 p.m.).

Copenhagen.—The Public Lighting Office of Copenhagen invite tenders for the installation of a central electrical station at the Valley gasworks in accordance with conditions and drawings which can be inspected at the Ostre and Valley Gasworks, or obtained therefrom on payment of £1. 2s. 3d., which will be returned provided a tender is sent in in due time, accompanied by the drawings, etc. Tenders must be sent in to the Director for Public Lighting, 22B, Vestre Boulevard, Copenhagen, by noon on Jan. 23.

Madrid (Spain).—An application has been made by the Société Générale des Tramways de Madrid et d'Espagne for a concession for an electric tramway in Madrid to extend the existing Northern Madrid tramway. Tenders, which will be adjudicated on Feb. 25, are invited for this concession on more favourable terms than those proposed by the company in question. The adjudication will turn in the first case on the reduction of the tariffs proposed, and if two or more identical proposals are made, a further verbal adjudication will take place with a view to the reduction of the period of the concession (60 years).

London, W.—The Great Western Railway Company invite tenders for the supply and delivery of the following material required in connection with the electrical equipment of the Hammersmith and City Railway, etc.: (Specification No. 8) steel conductor rails, cast-iron and steel ramps and fastenings; (9) porcelain insulating supports and their fastenings for conductor rails; (10) copper bonds, insulated cable connections, cable terminals, bonding presses, and accessories for connecting up conductor rails. Tenders, addressed to the Secretary, Great Western Railway, Paddington Station, W., will be received on or before Jan. 3.

Melbourne.—Tenders will be received at the office of the Deputy Postmaster-General until noon on Feb. 7 for the supply and delivery of (1) 3,500 trunk-line multiple jacks, in strips of 20; (2) 1,320 yards of 64-wire wool-insulated switchboard cable. Specifications may be seen at the General Post Offices at Melbourne, Sydney, Brisbane, and Adelaide. Tenders, endorsed "Tender for ——," as the case may be, addressed to the Deputy Postmaster-General, Melbourne, may be deposited in the tender-box at the General Post Office, Melbourne, or, if sent by post, must be prepaid and registered. The deposit to be enclosed with the tender is 5 per cent. on the total amount.

Porto (Portugal).—The Town Council opens a competition, which will close on March 15, at 3 p.m. precisely, for the concession of the exclusive right of the working of tramways for collective transports of passengers, luggage, and goods in all the municipal public ways, present and future, which favour that service, or in a special way within the limits of the town of Porto, according to the conditions approved in the meeting of Dec. 1 of the present year. The bases to which the eighth condition refers, the Herman Lourenzo Feuerheerd's request, and the rates, with the minima of the journeys, and the maxima of the prices of the passages, are published to the town hall's office for those who want to examine the conditions of the competition. The conditions of the competition are published to the Portuguese Consulate in London.

RESULTS OF TENDERS.

Bermondsey.—The Borough Council have accepted the tender of Sweet Bros., of Hampstead, for electric wiring at Rotherhithe Town Hall, at £33. 17s. 6d. The highest tender was £118. 10s.

Southend.—The Town Council have accepted the tender of Wimshurst, Hollick, and Co., at £415, for the provision of a new electric crane in lieu of the old steam crane now used on the loading pier.

Withington.—The Guardians of Chorlton Union have accepted the tender of Smethurst and Co., 67, Trevelyan-buildings, Corporation-street, Manchester, for electric lighting of old nurses' home, Withington Workhouse.

Kingston-on-Thames.—The Town Council have accepted the tender of Siemens and Co., at £174, for the supply of half a mile of 1 high-tension armoured cable; and that of Henley's Telegraph Company, at £115, for half a mile of 5-ampere and a like quantity of 20-ampere twin house service cable.

Cardiff.—The Electric Lighting Committee have accepted the following tenders for new plant for the extension of the Roath power station, which is to be made to meet the increased demand for electric lighting in the town: Musgrave and Co., Bolton, two 1,600-i.h.p. engines, with extras, £14,304; General Electric Company, Birmingham, two 1,100-kw. generators, £3,114.

BUSINESS NOTES.

TRACTION.

Raworth's Traction Patents, Limited.—Letters of allotment were posted on the 23rd inst. The company commences business with orders for 65 cars.

Dover.—The Corporation held a special meeting last week to inspect the plans and drawings in connection with the River light railway scheme, and it was decided to invite tenders, returnable on Jan. 10.

Llanelly.—A special meeting of the Estates Committee of the Town Council was held last week for the purpose of considering the agreement with the traction company, but the proceedings were held *in camera*, and the result has not so far been made public.

Birmingham.—An informal offer has been made by the traction company to instal a section of track on the Kingsland surface-contact principle, the company to work the line for a certain period, and, if it prove unsatisfactory, to substitute overhead equipment free of charge.

Kirkcaldy.—A movement is on foot for extending the Corporation tramways to Dysart. It is understood that the Dysart authorities are likely to guarantee against loss to the extent of 2½d. on the rates, while Sir Michael Nairn and other local gentlemen are offering a further guarantee against loss.

Newark and District Light Railways.—The Balderton Parish Council have unanimously approved of this scheme, and have appointed representatives to support it at the enquiry which the Light Railway Commissioners will hold shortly. The draft order names five years as the period for completing the system.

Ashton.—The construction of the new line to the borough boundary at the County Bridge, Dukinfield, which will be about 700 yards in length, has been commenced. The question of its lease to the Stalybridge Joint Board, when completed, has not yet been settled, there being a difference as to the amount payable to Ashton for the use of the line.

Bury.—At a meeting of the Bolton Corporation the Bury Corporation notified their intention of presenting a Bill to authorise the construction of tramways between Radcliffe and Ainsworth. The Bury Corporation also deposited plans with the Bolton Corporation for the proposed extension of tramways joining up to the borough boundary at the Coach and Horses.

West Cumberland.—The Whitehaven Rural District Council have received notice from the West Cumberland Tramways Company with regard to their application to Parliament for extension of time. Last year, when the Bill was before Parliament, the Council assented, and they have decided to do so again. As we mentioned in our issue of the 2nd inst., there are now signs that the scheme is to be proceeded with.

Hobart (New Zealand).—Hobart has had electric tramways for 11 years, the shares in which are mostly owned in Britain. Last year over two million passengers were carried, the average being about 5,500. It may be mentioned that the company is not extending its rails, but is importing motor 'buses to take passengers further afield. It is proposed to undertake electric lighting, for which the company has power under its incorporating Act.

Middlesbrough.—An account of a resourceful act by a motorman comes from Middlesbrough, where Driver Bates observed a child, unconscious of danger, standing on the track. The child did not move when the gong rang, and as it was impossible to pull up the car in time, the driver swung himself in front of the car, and after moving the child with his feet from the track, swung himself back to his post, his promptitude exciting the admiration of the witnesses.

Falkirk.—The Falkirk and District Tramways Company and the Town Council are at issue on the question of power supply. The former propose to take the current for their electric cars from the Scottish Central Electric Power Company, and the Town Council, who have a lighting and power plant, have resolved to write to the company pointing out that, according to the Act, the Scottish Central Power Company are precluded from supplying energy for use within the town of Falkirk.

Coventry.—A lengthy discussion ensued at the meeting of the Town Council, when the Streets Improvement Sub-Committee, after an interview with Mr. Winslow, engineer to the tramways company, recommended that the question of opposition to the tramway company's Bill, seeking an extension of time for reconstruction, remain in abeyance for a month in order that it might be seen what progress is made with the work under the altered arrangements made by the company with their contractors. Eventually the matter was referred back to committee.

Rochester.—The first section of the Rochester municipal tramway has been inspected and passed by Major Pringle, the Board of Trade inspector, and the line, which is on the overhead system, has been opened to the public. This line brings Rochester into direct tramway communication with Chatham, and the Gillingham and Chatham Light Railway Company, by agreement with the Rochester Town Council, will operate it as part of their system. The other sections of the Rochester municipal tramways will be deferred pending the adoption of a scheme of main drainage.

Digitized by Google

Leicester.—With the opening last week of the Fosse-road circular route and the Groby-road route the whole system of electric tramways in Leicester has practically been completed. Twelve cars will work the former route, which is expected to prove one of the most popular and best paying on the whole system. All parts of the town now possess an excellent service, but the committee are making a few experiments in the running arrangements for the different routes so as to work the system to the best advantage.

Bournemouth.—The result of the arbitration between the Corporation and the Poole and District Electric Traction Company in connection with the purchase by the Corporation of the company's lines between Poole and Bournemouth and the rights they possess in Bournemouth and Christchurch districts is that the umpire, Mr. Justice A. T. Lawrence, and the referees, Mr. W. Eve and Mr. R. Vigers, have fixed the price at £112,000, the Corporation to pay the costs of arbitration. The company's original claim amounted to some £450,000, while the Corporation's estimate was between £60,000 and £70,000.

Cardiff.—Mr. Ellis recommends a parcels service, which, he anticipates, will earn an appreciable revenue. The Corporation look upon the suggestion with favour, and are to consider it further on a report from Mr. Ellis. Another recommendation on the part of Mr. Ellis has been accepted by the Tramways Committee, and will be presented to the Council. This is that, instead of all the cars following a through route, some of them should serve particular districts, so as to provide an adequate number of trams for the busy districts. It is also proposed to eliminate several stopping places, the present speed of the cars being low.

Underground Railway Fares.—It is highly probable that after all zone fares will not be adopted on the District Railway. The firm refusal of the Metropolitan Railway to discontinue 1d. fares and the issue of season tickets has considerably increased the difficulties of the adoption of the scheme, and made it practically impossible, as far as interchange tickets on the Inner Circle are concerned. The District Railway, who hitherto have refused to grant renewals of season tickets beyond Dec. 31, 1904, now announce that for the present they will continue to issue monthly season tickets. This change of attitude on the part of the directors is regarded in well-informed quarters as the first step towards the abandonment of the zone system.—*Daily News.*

Ilford.—At the meeting of the Urban District Council, Councillor Bailey proposed that the Council should consider the surplus moneys standing to the credit of the tramways undertaking and decide how much may be applied to specific purposes; and also generally lay down the principles upon which annual surplus sums shall be dealt with in the future. The profits up to date total about £7,000, as last year there was a profit of over £4,000, and the councillor anticipated that this balance would be maintained during the current year. He contended that the balance should now be definitely earmarked. If £4,000 were invested at 3½ per cent. for 25 years it would amount to £161,253, or £22,000 more than the undertaking originally cost, so that at the end of that time they would have paid off their obligations and saved £161,000 for the benefit of the coming generation, but it was only fair that the present ratepayers should be considered. He suggested that £2,000 a year should be put by, and that the other £2,000 should be expended in the relief of the rates, which stand at 7s. 10d. in the £. Eventually it was agreed to refer the matter to the Tramways Committee for report.

Melbourne.—The Bill to authorise the construction of an electric tramway from St. Kilda to Brighton Beach, Melbourne, has been circulated. The expenditure for the construction of the line, excluding rolling-stock, is limited to £19,500, payable out of the Country Tramways Trust Fund. The average wage to be paid to the workmen employed in the construction of the line is to be equal to 7s. per day of eight hours. The width of land taken from the line is not to exceed 33ft. except at stations or other points where a greater width is necessary. The local municipal councils are indemnified in respect to any accident which may happen in consequence of the work. The construction of the line is contingent on a guarantee being given by the two municipalities for payment of interest at the rate of 4½ per cent. on the total cost of construction, including land and equipment. In the event of Crown land at Elwood being enhanced in value, the enhancement is to be set off from time to time as the land is sold against the cost of construction. It is also provided that if there is a profit on the line in one year such profit is to go in reduction of the amount payable under the guarantee in any other year. The maintenance of the road when the electric railway is laid is imposed on the Railway Commissioners. It is not proposed to erect a special power-house for the generation of electricity, the present intention being to make arrangements with the power company.—*N.S.W. Railway Budget.*

Swansea.—A special meeting of the Tramways Committee has been held for the purpose of having explained to them the various clauses in the draft lease between the Corporation and the tramways company with reference to the leasing of the new tramways in the borough. The deputy town clerk explained that the Brynhyfryd section was to be leased under the Tramways Act, and the remaining sections under the light railway order. Regarding the latter, the rent to be paid by the company is as as follows: an amount equal to the interest which the Corporation have to pay all on all capital property expended in the construction of the works, together with the further sum equal to 3 per cent. per annum on such capital, and, further, in the event of the company in any year paying interest on its capital expended on the existing tramways and proposed light railways, amounting to 6 per cent., the company to pay to the Corporation a further sum equal to 1 per cent. per annum. With regard to the Brynhyfryd section, the rent to be paid is as follows: for the first seven years of the lease a sum equal to 5 per cent. upon the capital expended, for the next seven years 6 per cent., and for the remainder of the term 7 per cent. In both instances all rates, charges, assessments, impositions, and outgoings, and outgoings in respect of the tramways and light railways, are to be paid by the company. It was decided to send a copy of the proposed lease to all the members of the Corporation for the purpose of inviting suggestions.

Glasgow.—With reference to the proposed extensions in the direction of Barrhead on the part of the Corporation and the Paisley District Tramway Company, about which we had a note last week, a deputation of the Barrhead Town Council waited the other day on the Tramways Committee of the Corporation, with a view to further discussing the details of the proposed introduction of the electric cars into Barrhead. When the first tramway scheme was submitted by the Glasgow Corporation it was proposed to run the cars along Main-street and Cross Arthurlie-street to the Joint Line Railway Station. This would have involved an awkward lowering of the roadway underneath the Caledonian Railway bridge, and in the present scheme it is proposed to terminate the line in Main-street at the Cross Arthurlie corner. Mr. Murphy, of the Paisley Tramways, is also seeking power to introduce his cars to Barrhead by an extension of the line which presently terminates at Potterhill. His idea is to bring his cars along Cross Arthurlie-street to a point in Main-street near the terminus of the Glasgow cars. There would thus be two awkward lowerings of Cross Arthurlie-street, the other being underneath the Joint Lines bridge. These proposals are not meeting with the approval of the public, to whom they mean considerable inconvenience. Passengers could not travel the full length of the burgh without changing from one system to the other, a change which would be necessary for most people wishing to reach the railway stations. Over and above this there is the disfigurement of Cross Arthurlie-street. The feeling of the community seems favourable to the Glasgow cars being run on to the Joint Line Station, as originally proposed, thus traversing practically the whole length of the burgh. The Paisley cars could turn on the other side of the station, and Cross Arthurlie-street would be cut up only at one point. This view of the matter was discussed at the conference with the Barrhead representatives, but the result has not yet transpired. The Upper District Committee have decided to stipulate with the company for a double line throughout in connection with the proposed extensions from Glenfield-road to Barrhead and from the boundary at Johnstone to Kilbarchan. This will entail considerable street widening. The committee have resolved to take no action with regard to the notice given by the company relating to the abandonment of two short lengths of line.

Sheffield.—The *Daily Telegraph* of this city publishes an interesting *résumé* of the past year's working of the trams. More than a million passengers have been carried in excess of the total last year, the number up to the 4th inst. aggregating 62,579,886, and the receipts amount to £235,939, an increase of over £7,000. The car miles run have been 5,658,926, which is considerably more than a million over the number last year. The total number of cars is 247, an increase of 29 on the year, and the average number of ordinary cars running daily has been 138 6-7, and special cars 58. There are 64 miles 6 furlongs 2·4 chains of single track (excluding depôts), and the total number of employés is 1,386. Mr. A. R. Fearnley was appointed general manager in succession to Mr. A. L. C. Fell on Jan. 14 last, and several changes have followed. The bell punch and ticket department, including the supervision of cashiers and collection of traffic receipts, formerly under the supervision of the city treasurer, is now under the direct control of the general manager. By thus doing away with dual control a saving is anticipated in the management of the department. The erection of the Queen's-road car-sheds is now practically complete. The various workshops are being fitted up; tenders have been accepted for the machinery required; heating apparatus has been fixed; and the extensions are being fitted with electric light by the Sheffield Corporation electric supply department. It is interesting to learn that the automatic point controller, which was fixed at the junction in High-street in June last, is working very satisfactorily. Various improvements have been carried out on the cars during the year. About 230 vehicles have been fitted with the "hanging gate" type of lifeguard, and the remaining cars will shortly be fitted in the same way. Outside end indicators, with the name of the route in full only, have been ordered, and are being fitted on all the vehicles. Twelve double-deck cars with top covers are under course of construction at the Nether Edge depôt. One old horse car has been converted into an electric car. The committee have decided to order a further lot of 30 car top covers from Messrs. G. C. Milnes, Voss, and Co., of Birkenhead. The following new routes and extensions have been completed during the past year: Shoreham-street, Wolseley-road, siding in Cherry-street, Bramall-lane; Nether-green terminus, Snig-hill, Bridge-street, Suffolk-road, and Queen's-road. The question of running motor omnibuses from some of the present outside termini to outlying districts has been considered, but as the Corporation have not the power to run such vehicles under the existing Acts, the committee have decided to defer the matter, and to apply for the necessary powers in the next parliamentary Bill. During the year grants of free tram tickets amounting to about £53 have been made by the Tramways Committee to various nurses' associations, etc., in the city. The rate of pay for conductors has recently been increased, and, to complete the review, the clause limiting liability for accidents to £25 has been abandoned.

London County Council.—Mr. J. D. Gilbert, the Progressive Whip, is reviving his scheme for a southern embankment between Westminster and Blackfriars Bridges so as to provide a suitable site for a new county hall, with a service of trams between. The question of bringing the trams over the bridges was referred to at last week's meeting of the City Corporation, but the proceedings were of a formal character. Colonel Dunfee stated that the Streets Committee had had a long and amiable discussion with the members of the County Council on the subject, views being exchanged without either party being pledged. The committee had passed a resolution stating that they were not in a position to recom-

Digitized by Google

mend the Common Council to do anything in the matter at present. Since the subject of London street traffic is under the consideration of the Royal Commission, and until its report has been issued, the Streets Committee think it would be unwise to come to any decision. The committee recognised, however, that trams within the City would be most useful in some respects. He suggested that the meeting should pass a resolution approving the action taken by the committee. Mr. Campbell said he thought they should drop the matter entirely. It would then be understood that they left the matter in abeyance until the report of the Royal Commission was received. Colonel Dunfee said his idea in bringing the matter forward was to give the electors an opportunity of expressing approval of the action taken by the committee. Mr. T. V. Bowater proposed "That this ward meeting approves of the action taken by the Streets Committee of the city of London on this question." Mr. Campbell seconded, and the motion was carried unanimously. At last week's meeting of the County Council a joint report was submitted by the Bridges and Improvements Committee on the question of removing Charing Cross railway station to the south side of the river, the widening of Hungerford Bridge, and the construction of a double line of tramways over the bridge so as to link up the northern and southern systems of tramways. They expressed the opinion that, having regard to the very large expense involved, and also having regard to the attitude of the South-Eastern Railway Company, there was no alternative but to advise the Council for the present not to give further consideration to the matter. At the request of Mr. J. Burns, the report was ordered to stand over until after the recess. Mr. J. Allen Baker, chairman of the Highways Committee, discusses at great length the subject of the New York Underground Railway, which he visited on behalf of the Council, and on which he has prepared a report. He regards the system as one of the great achievements of the age. A considerable portion of the subway had to be cut through solid rock, huge buildings had to be undermined, a complicated network of pipe, mains and cables had to be dealt with, sewers had to be diverted and reconstructed, and the street railways (elevated and surface) had to be underpinned, and their daily running and the general street traffic maintained without interruption while the subway construction work proceeded underneath. Notwithstanding these obstacles the system was constructed expeditiously, and practically without inconvenience to the public. The way in which the New York Rapid Transit Board has sought a solution of the street problem in its city is, he thinks, suggestive of what should be undertaken for London "if the same problem, which is equally pressing here, is to be solved." The electrification of the District and Metropolitan Underground Railways and the lines in connection therewith constitute, in his opinion, an important step in the co-ordination of London locomotion, but the real solution, he is convinced, is to be found in the further electrification and extension of the County Council tramways, and in the construction of further subways under some of the streets in the more central parts to make east and west, as well as north and south, connections. "New York has shown us an example of what enlightened civic enterprise can accomplish. London has the opportunity, with its existing tramway systems and its first tramway subway under construction, to extend, connect, and build up a complete and uniform system for the whole of the county that will be a credit to the capital of the Empire," concludes Mr. Baker. The estimates for street widenings submitted by the Finance Committee—viz., £21,500 in respect of the Lordship-lane and Forest Hill tramway, £103,300 in respect of the tramway from Lewisham High-road to Forest Hill, £149,300 in respect of the New Cross-road to Lee Green tramways, £26,050 for the Greenwich and Catford tramway, and £14,400 in regard to the tramway from Bostal-hill to Kneehill have been approved.

LIGHTING AND GENERAL.

Bridlington. — On Wednesday a report was adopted which estimated the total cost of street electric lighting at £2,107 for 43,703 c.p.

Pearith.—An enquiry has been held into an application by the Urban District Council for power to borrow £6,850 for purposes of electric lighting.

Wellington.—The Urban District Council's electric lighting order has been referred for further consideration to the former Electric Lighting Committee.

Sale of Plant.—The West Ham Electric Lighting and Tramways Committee have various plant for sale. Particulars appeared in an advertisement in our last issue.

Worthing.—An enquiry has been held into the Town Council's application for sanction to borrow £1,600 for the purpose of the extension of electric lighting mains.

London Gazette.—The partnership between John Thomas Mayfield and Thomas Champness, electrical engineers, 63, Cannon-street, London, has been dissolved by mutual consent.

Acton.—The consulting electrical engineer has reported upon the progress of the laying of electric cables in the district, and on the plant at present being manufactured. It is expected that the Council will be ready to supply electric light by the middle or end of January.

Stratford-on-Avon.—The Town Council are applying for a provisional order under the Electric Lighting Acts, 1882 to 1899, to extend the time limited by the order of 1901 for laying the mains in the compulsory area, and to allow the transfer of powers to a company.

East Indian Railways.—The arrangements for the electric lighting installations for the ferry steamers "Tara" and "Lakshmi," which ply in connection with the Sakrigally-Manihari ferry service, have been sanctioned at a cost of about Rs.24,000.—*Indian Engineering.*

Stock Exchange.—The Stock Exchange Committee have appointed Jan. 5 a special settling day for W. T. Henley's Telegraph Works Company, Limited, further issue of 5,000 4½ per cent. cumulative preference shares of £5 each, fully paid, Nos. 35,001 to 40,000; and have ordered the said securities to be quoted in the official list.

Beckenham.—At the last Urban District Council meeting, the following resolution was discussed: "That it be referred to the Electric Lighting and Tramway Committee to consider and advise the Council as to the advisability of extending the lease of the Beckenham electric lighting undertaking." The motion was lost by ten votes to five.

Lahore.—Sir Thomas Higham, representing the Punjaub Power Association of London, has arrived here with the object of acquiring from the Government concessions enabling him to harness the enormous water power, and especially the irrigation canals of the Punjaub, which has hitherto been wasted, and to supply electricity wholesale.

Dunfermline.—Notice has been given for the February meeting of the Council to go forward with the electric lighting provisional order. In the meantime a committee is to negotiate with the Fife Electric Power Company again in conjunction with Mr. Sayers, and try to come to an agreement whereby full control of the town would be in the hands of the Council.

Removal.—Messrs. A Ransome and Co., Limited, engineers and ironfounders, Stanley Works, Newark-on-Trent, are removing from 304, King's-road, Chelsea, S.W., on Saturday, the 31st inst., and will open new London offices at 63, Queen Victoria-street, E.C., on Monday, Jan. 2, in charge of Mr. F. W. Baker, who has been connected with the firm for the past 23 years.

Mexico.—The following applications are recorded: By Señor Gustavo A. Lilliendahl for the appropriation, for the production of power, of 1,500 litres of water per second from the River Arteaga, municipality of Arteaga, state of Coahuila; and by Señor Luis Urquiza for the appropriation, for the production of power, of 12,000 litres of water per second from the River Lerma, district of Maravatio, state of Michoacán.

Leven.—The post office has been extended by the addition of rooms at the rear providing accommodation for telephone instruments, etc. Mr. Hunter has in the commodious room set apart for telephone work secured a double-switch section, enabling the staff to have one trunk to Dundee, three to Kirkcaldy, an additional one to Glasgow, two to Edinburgh, and two to the East Coast, the Edinburgh and Anstruther offices to be connected shortly.

Huddersfield.—The borough engineer in his last report states that the number of consumers in December was 2,026, as compared with 1,999 in November, showing an increase of 27. The number of lamps connected in December was 139,028, as against 137,643, an increase of 1,385. Sanction has been received to the borrowing of £4,300 for the purpose of the extension to Golcar. A special sub-committee is about to report on the development of motive power.

Chelsea Electricity Supply Co.—The company's Bill provides for the extinction of the 500 £1 founders' shares in the company. As a result of negotiations between the directors and the holders of these shares, an arrangement has been come to for their surrender in consideration of the allotment and issue to the holders of 10 fully-paid ordinary shares of £5 each for every founders' share. In accordance with this preamble, the Bill provides that on "the thirtieth day after the passing of this Act" the founders' shares shall be converted and the capital of the company reduced by £500.

Longton.—The Corporation Gas and Electricity Committee, finding the use of electricity for motive power purposes gradually extending and coming into favour with manufacturers and tradesmen, have decided to make a reduction in the price charged for current used for motive power, hoping thereby to still further encourage its use. For the future, the following is the reduced rate at which current will be supplied for electric motors: for 500 units per quarter or less, 2½d. per unit; above 500 units, and under 1,000 per quarter, 2¼d. per unit; above 1,000 units, and under 1,500 per quarter, 2d. per unit; above 1,500 units, and under 2,000 per quarter, 1¾d. per unit. The price paid by consumers of electricity for lighting purposes last year averaged 4¼d. per unit.

St. Austell.—On the 22nd inst. the town was again lit up with electricity. About 12 months ago Messrs. Veale and Co. ceased to supply the light, and the undertaking was taken over by the St. Austell and District Lighting and Power Company. The company then erected a new station, and put in new plant at a cost of £7,000. Two 85-h.p. engines and three dynamos have been fixed. There are two sets of producers. A new cable has been laid, nearly a mile in extent. The general lighting is on the direct-parallel system. There is an accumulator battery for the supply from midnight and during the small hours. The company has secured about 75 per cent. of the old consumers. The charge for current is 5d. per unit. The works are under the management of Mr. A. Childs.

Swansea Telephones.—The Telephones Committee have decided to make provision for placing 260 new subscribers on the present switchboard. The consulting engineer estimates the cost of cables and ducts for the underground extension at £727. Henley's (the only tender) price was £884, and Mr. Bennett has been instructed to obtain tenders for cables for extensions, the committee deciding to do the work themselves. The committee have decided to retain his services in the expenditure of £2,000 to be expended for the extensions, etc. The question as to the practicability of placing an instrument in St. Mary's Church and the various halls to enable subscribers to enjoy organ recitals and concerts without leaving their homes, has been referred to Mr. Mackay for a report.

East Barnet.—At the last meeting of the East Barnet Valley Urban District Council the chairman reported on his interview with

Digitized by Google

Mr. Pelham *re* the Council's application for extending the time of their lighting order. Mr. Pelham told the deputation that the Council had no right to hand over the order to a company, and that the Council ought to carry out the lighting themselves. He agreed to extend for another two months the time for carrying out the order, and said that if the Council wanted to do the work themselves they could apply at the end of two months to the Board, who might grant a further extension. The Board were in favour of councils themselves doing the work. If an application were made for an extension of time, with a view to getting a company to carry out the order, the Board would look with disfavour upon it. A long debate ensued. A motion "that the lighting of the district with electricity be undertaken by the Council" fell through, and the following resolution was adopted: "That the present sub-committee be authorised to continue negotiations with the North Metropolitan Company."

Liege Exhibition, 1905.—With reference to previous notices which have appeared in the *Board of Trade Journal* respecting the International Exhibition to be held at Liége in 1905, the following information has now been received from the Association of Chambers of Commerce of the United Kingdom: "An influential committee has taken up the formation of a British section, and has secured an option to take the whole available space reserved for this country. The British section in the machinery hall is already full, and no further applications from exhibitors of machinery in motion can be entertained. In the industrial section a good many exhibitors have taken spaces, and it is hoped that exhibitors will come forward in large numbers so as to make the British section compare favourably with that of other nations. The fact that the autumnal meeting of the Association of Chambers of Commerce will be held at Liége should give an increased interest to the exhibition and add much to its popularity with exhibitors as well as visitors. The Commissioner-General is Mr. Thomas Cope, to whom all applications for space should be addressed at the British Commissioner-General's Office, 54, Great Tower-street, London, E.C.

Special Indian and Colonial Trade Enquiry Offices.—India: The India Trade Enquiry Office at 73, Basinghall-street, London, E.C., has been established for the purpose of supplying the general public with all available information as to the commercial products, manufactures, and trades of British India. The office is under the superintendence of an India Office official, who is in daily attendance to answer personal or written enquiries. The current publications of the Government of India dealing with Indian trade statistics, tariff charges, railways, economic products, etc., are kept in the office, and can be consulted free. The various Indian directories are also filed. Canada: The Canadian Government have secured premises at 73, Basinghall-street, London, E.C., where an office has been opened, under the designation of "High Commissioner for Canada, City Trade Branch," for the convenience of the commercial community. In due course it is intended to equip and maintain a display room, illustrating the products, resources, and manufactures of the Dominion. In the meantime a Canadian representative attends daily to deal with enquiries and applications in connection with Canadian import and export trade, and to supply information about Canadian matters generally. Personal appointments can be arranged when desired. Cape of Good Hope: The Government of the Cape of Good Hope have opened offices at 73, Basinghall-street, London, E.C., for the purpose of a commercial agency for that colony which will be under the direction of the Agent-General for the Cape of Good Hope. Mr. Lewis Atkinson, who has been appointed commercial agent, attends daily to deal with enquiries on all commercial and trade matters connected with Cape Colony. Queensland: For the convenience of the commercial community in the City of London, the Agent-General for Queensland has opened a branch office at 73, Basinghall-street, London, E.C., where a representative attends daily to give information to enquirers regarding trade, mining, and all other matters in connection with Queensland. A reading-room will also be provided, in which maps, directories, statutes, Government reports, and other publications of the State can be seen.—*Board of Trade Journal.*

Tredegar.—The conflicting interests of the Council, who prefer to use electric light themselves, but would like others to continue using the municipal gas, have led to a ridiculous position at Tredegar. Last week an application by the Tredegar Company came before the Special Gas and Water Committee for permission to carry electric wires across the roadway between the Tredegar company's stores and general offices, and was deferred, and the clerk was instructed to intimate to the company that the work was not to proceed until the necessary permission was granted. In answer, the company wrote a letter, which explains the situation succinctly, as follows: "With reference to electric light passing over the highway between the stores and the offices of the Tredegar Company, we are very much surprised to note that you decline permission for us to carry an electric main between our stores and the offices. We cannot understand this, seeing you have already given us permission to cross the highway with the main lighting wires between Tytrist and the works, and now refuse us permission to light our offices from this main. We must point out that you yourselves are using electric light supplied by the company at Bedwellty, and are arranging to do the same at Pochin. It seems to us an extraordinary position that you should refuse us permission to light our offices with electric light on the one hand, and on the other hand you ask us to supply the same to meet your convenience at the above-mentioned places. We shall be glad, if possible, if you will consider this matter before the 11th prox., as we are desirous of putting this work in hand at once. We may say that the whole of the office staff have suffered from the inefficiency of the gas light, and it is in order to obtain the best light under the healthiest conditions that we wish to instal electric light, and your opposition of this, seeing the way you have already committed yourselves in the matter, certainly requires some reasonable explanation. Our only reason for deferring the lighting of the offices was in view of the reconstruction of the offices, which has since been postponed, and we wish to proceed with the lighting straight away." A debate ensued, a member remarking that they had formed their resolution and he hoped they would stick to it. Others said the Council had granted permission to cross the road down below and they refused permission to cross the road above, because they did not lose anything by the former permission, but if they granted permission in this case there would be no gas consumed in the company's offices. Finally, the committee refused to pass any resolution on the matter.

Cape Town:—From the annual report of the city electrical engineer, Mr. Walter F. Long, A.M.I.E.E., we note that considerable changes have taken place in connection with the plant at the various generating stations belonging to the Corporation during the year ended June 30, 1904. Due to the increased size of the generating units, the steam plant at Molteno was shut down, and the 150-kw. Bumsted and Chandler set, and the Belliss-Mather and Platt units were removed from Dorp-street, and from there temporarily in an old shed at Dock-road respectively to the new power-house at Dock-road, where one of the new 700-kw. machines was switched on with supply on April 14. This practically completed the movement of placing the whole of the generating machinery under one roof, and consequently the cost of generation has been reduced, and also there has been a considerable increase in the consumption. The whole of the condensing plant, with the exception of the "Klein" and cooling tower, is now erected, four Davey-Paxman boilers are under steam, and it is proposed to shut down for a while the Babcock boilers in order to overhaul the economisers. Mr. Payne, the station superintendent, left the employ of the Council last month, and it was decided not to fill the vacancy. The running of the plant is now left in the hands of the two senior shift engineers, and the construction work undertaken by Mr. Cooke, formerly in charge of Dorp-street and Molteno. Considerable alterations and additions have been carried out in connection with the mains for the distribution of electric energy, and a large number of arc lamps have been erected. During the year a considerable amount of work has been carried out in connection with the electric light installation and the new city hall. Messrs. Cunningham and Gearing were the contractors. The electrical standard instruments in the test-room are all set up and in constant use. New wiring regulations were promulgated in the Government *Gazette* of Sept. 15, 1903. These regulations give the Council power to refuse to connect up defective installations, and under the rigid enforcement of the same the class of electrical material and the standard of workmanship has greatly improved. In September an alteration was made, increasing the hours, by about 40 per cent., during which energy is obtained at the half rate; this is equivalent to reducing the price of current to day consumers. The day consumption to private consumers has increased from 353,809 units for the year ended June 30, 1903, to 511,457·2 units for the corresponding year in 1903-04, equivalent to an increase of 44·8 per cent. In 1901-02 22 per cent. of units sold to private consumers were supplied in the daytime, in 1902 03 33½ per cent., and in this year 40·1 per cent., equivalent to 30·6 per cent. of the total units sold. There are at present connected 1,307 consumers, with 86,191 8-c.p. lamps, as against 20 with 2,100 in 1895. In 1896-7 a consumer took on an average 350 units per annum; in 1902 3, 1,004; and last year, 973·5, the falling off being due to the large increase in connections made to small houses. The motors connected are equivalent to 1,727 h.p., as against 1,011 h.p. in the preceding year. We draw attention to the fact that Mr. Long recommends that a more up-to-date reversible booster be obtained, as the accumulator battery in its present condition is quite capable of giving 300 to 350 amperes for a couple of hours or so, whereas the present booster will only allow of a maximum discharge of 150 amperes.

Sheffield.—The *Sheffield Daily Telegraph* gives the following interesting *résumé* of the Corporation's electric light undertaking during 1904: Another year of progress has to be recorded for the electric light department of the Corporation. It has seen the opening of the new power station at Neepsend, a scheme which is evidence of the foresight of the committee in acquiring a site and erecting plant which, although not yet fully employed, will, with the increasing demand for electricity for illumination and motors, gradually come into operation. Under the superintendence of Mr. S. E. Fedden, the general manager and engineer, the power house has been admirably equipped, and Sheffield now possesses a source of supply worthy of the city. One of the most interesting features in connection with the department this year has been the increasing demand for electricity for driving machinery. A few years ago only a very small number of motors were used by customers of the department. But a remarkable change has occurred, and to-day motors may be found driving all kinds of machinery—rolling-mills, grinding wheels, pneumatic and power hammers, annealing furnaces, steel tape, tempering and grinding machines, wire-drawing machines, lathes, saws, buffing lathes, and quite a host of other machines. As a leading Sheffield engineer recently said, "The greatest revolution that steelworks have experienced of recent years has undoubtedly been the introduction of electric driving, and the engineer of ordinary ability has found in electricity a simple means for remedying extravagance in works more readily than by other methods." This departure in the use of electricity instead of steam in Sheffield is a sign of the times. It is anticipated that a few years will see a remarkable development in the Corporation department owing to this change alone, and with such a prospect it is satisfactory to learn that the committee have invested in a powerful station. During the past year there have been applications for electric motors to the extent of 115 h.p. Several cutlery firms are now having their machinery driven wholly by electricity. There are 20 elevators for passengers and goods being worked by electricity, and a large number of travelling cranes are also being worked by electric

Digitized by Google

power. A "boom" in trade would probably make a vast difference in the power supplied, and lead to a much more extensive use of motors. A few statistics may be interesting. The customers have increased in number during the year from 2,549 to 3,000. The lamp connections have reached a total of 275,363. The units sold up to last March were 2,980,049; it is estimated that five millions will be reached at the end of the current year. After paying all charges, the department had a surplus at the end of the financial year of £5,431, against £6,534 at the end of the previous year. In this connection it must be remembered that interest is being paid on a large amount of capital which has not yet become revenue earning. Several new features in electrical illuminants must have been observed recently in Sheffield. One of the most striking is the brilliant arc lamp, which is growing in favour for lighting shop fronts. The brilliancy of the light is undoubted. The lamps have not yet come into general use, but there are now about 20 in the city. For interior lighting the Nernst lamp is rapidly growing in popularity. This is being regarded as a dangerous rival to the incandescent gas lamp. Taken as a whole, the past year has been one of undoubted progress in the department. The opening of the power station at Neepsend has been an important step, the resources which are contained there for providing light and power being sufficient probably to meet the demands of the city for many years to come; and the sooner the value of the resources is appreciated, the better it will be for the department as a revenue-earning concern.

"Year Book of New South Wales."—This handbook, compiled by Mr. Coghlan, the editor of "The Year Book of Australia," for circulation by the Agent-General in London, Westminster-chambers, 9, Victoria-street, Westminster, S.W., has been brought fully up to date. Among other valuable information given is the following: The annual value of the goods imported into and exported from New South Wales affords the surest test of its material advancement, rising from £400,000 in 1825, when the official records begin, to £53,508,280 in 1903. The progress of the trade of the State is shown by the following amounts, in decennial periods: 1825, £400,000; 1835, £1,796,998; 1845, £2,789,840; 1855, £7,552,649; 1865, £20,199,325; 1875, £27,532,530; 1885, £40,487,568; 1895, £37,927,200; 1900 (quinquennium), £55,725,587. The value of imports during 1903 was £26,770,169, and of exports £26,738,111, the total trade being at the rate of £37. 12s. 2d. per head of population. In 1825 the value of the exports from New South Wales was £100,000. Ten years later, in 1835, it had risen to £682,193, the subsequent decennial increases being: 1845, £1,555,986; 1855 £2,884,130; 1865, £9,563,818; 1875, £13,797,397; 1885, £16,750,107; 1895, £21,934,785; 1900 (quinquennium), £28,164,516; 1903, £26,738,111. The general character of the articles imported is illustrated by the following items included among the imports of 1903: apparel and attire, £850,940; bicycles, etc., £28,108; boots and shoes, £263,525; piece goods, £1,943,401; canvas, £50,926; iron, steel, and galvanised iron, £480,051; machinery, £866,358; arms, ammunition, etc., £430,771; agricultural implements, £203,318; beer in bulk and bottle, £191,501; cement, £36,835; drugs, etc., £131,252; earthenware and china, £76,716; fruit, green and dried, £416,904; furniture, £72,589; gloves, £61,190; lead, £147,892; paints and colours, £97,289; gold, £3,433,218; coin, £637,377; grain and pulse (prepared or manufactured), £2,525,980; grindery and leather, £206,075; hats and caps, £173,727; hay and chaff, £557,845; musical instruments, £91,549; kerosene, castor, and other oils, £332,522; live stock, £2,164,483; malt, £93,874; paper, books, etc., £511,265; silver and plated ware, £49,989; spirits, £353,736; medicines, £101,606; milk (preserved), £100,426; skins and hides, £489,984; sugar, £710,708; tea, £279,781; cocoa and chocolate (prepared and raw), £49,581; timber, £530,766; tobacco, cigars, and cigarettes, £363,796; tramway and railway plant, £185,675; fancy goods, £101,584; watches and clocks, £62,959; wines, £75,700; wool, £578,555; potatoes, £213,675; tallow, £29,273; tin and tinware, £323,870; bags and sacks, £162,028; fish (fresh, dried, and preserved), £165,594; copra, £156,827; floorcloth and oilcloth, £63,140. Many of the imported goods, such as wool and tallow, were intended for re-export, being sent from the other States for convenience in the work of shipment. The gross amount of duty collected by the customs during 1903 was £2,902,687. Of the exports from New South Wales during 1903, £7,559,759 was represented by exports to Great Britain, £8,992,930 by exports to Australasia, £2,190,347 exports to other British possessions, and £7,995,075 exports to foreign countries. A considerable portion of the goods exported from New South Wales consists of articles imported from Europe, America, and elsewhere. The value of these in 1903 was £8,072,307, leaving the sum of £18,665,804 to represent the value of the exported Colonial produce. Coal is, like wool, a staple article of export, the value of the quantity exported during 1903 being £1,704,993; gold is exported both in the form of coin and of ingots, the value of these in 1903 being £4,913,478. The copper exports were valued at £604,923, and those of silver and silver ores at £1,658,471. To these may be added the export of tin, etc., valued at £312,933.

Waipori Falls Electric Power Co. (N.Z.).—The *New Zealand Mining, Engineering, and Building Journal* in a leader on the purchase of the above undertaking by the Dunedin City Corporation says: "As the result of the private Bill promoted by the above company, the Dunedin City Council has agreed to purchase the whole undertaking for £31,000. The result of the evidence adduced before the Parliamentary Committee that sat on the Bill has amply demonstrated that the Dunedin City Council did not sufficiently go into the merits of the Waipori scheme as compared with the combined Taieri and Lee Stream scheme. What is evident from that evidence? It clearly shows that to provide 2,000 e.h.p. from the Waipori will only cost the city, even after purchasing out the present company, £80,000, whereas the cost to bring in the same power from the Lee Stream would be £104,000. Further, the Lee Stream is a doubtful supply, the whole evidence being that there was no assured supply in drought seasons or in frosty weather even for 2,000 h.p., while the evidence is that 6,000 h.p. could be got from the Waipori by the same expenditure as was required to supply 2,000 h.p. from the Waipori. For the adduction of this evidence we have to thank a Parliamentary Committee, as it was quite evident the City Council and their Tramways Committee burked all discussion, and were it not for the promotion of this Bill, the city would be committed to the fatuous and ruinous expenditure of £104,000 on a very third-rate water scheme. How, then, are we to account for the conduct of those who should be guardians of civic affairs in Dunedin? It was simply due to the fact that instead of treating this as a business proposition, these guardians were more concerned, not with the value of the water rights to the city, but with the fact that a syndicate were going to make more money out of it. To burke this syndicate in getting a fair price for these valuable rights the Council entered upon a game of bluff. Anyone who knows the card game of 'poker' knows how such a game ends if the bluffer holds an inferior hand and is compelled at last to 'show it' and pay up. That is exactly what the city has had to do in this instance. Had the city bought these rights in the first instance they would have saved money, and they would have to-day an hydro-electric power in the city at a cost of, say, £7. 10s. per horse-power, instead of £29 per horse-power, which it is at present costing them to generate with steam. The useless expenditure upon Lee Stream, which has cost more than £10,000, would have been avoided also. But supposing this Bill had not been promoted the whole of the city bungle in adopting a third-rate water scheme would have been buried out of sight, and perhaps for an indefinite period. The city is paying to the company £10,000 more than it cost the company. It must not be assumed, however, that this £10,000 is all loss. For the city has had the advantage of the works being so far constructed under private agreement, and we know from past municipal management that this means probably a saving of 33⅓ per cent. Then the company has a first-class engineer whose contract will be taken over by the city. If the City Council had to select such an officer, it would probably end in the selection of an incompetent and expensive man not acquainted with his business, as such appointments generally are. Then the city gets the benefit of the private contracts entered into by the company for the supply of the plant. It is probable, therefore, that the whole £10,000 paid to the company has been saved in the good arrangements made by the company, and which have been taken over by the Council. But this splendid water power has now been acquired by the city, and we have to congratulate the citizens of Dunedin upon that fact. There is little doubt that this is the best asset the City Corporation has now in its books, and one which will in the course of years altogether free the city from its indebtedness. This is apart altogether from the great advantages that will be conferred upon Dunedin by the supply of plentiful and cheap water-generated power. Of all the foremost cities in New Zealand, Dunedin is the one which is at present under the greatest disadvantage. Until the advent of large ships she was the foremost commercial centre of New Zealand. But with the advent of large ships her position as such a centre is gone. All the other harbours in the large centres (if we except Bluff) have better harbours than Dunedin. Even the Bluff is better off by reason of the large area of level and fertile land in its neighbourhood. It is only the freezing industry which has enabled Otago settlers to take full use of the large amount of hilly country in Central Otago for sheep growing that has kept Dunedin from decadence. But Dunedin has always been a manufacturing centre, and it is the building up our position in that respect (for which cheap power is necessary) that we must look to support the city in case of a set-back should come to our foreign meat trade. Fortunately, the City Council has been forced into the position of acquiring this cheap power. For that we have to thank, not the City Council of Dunedin, but the enterprise and energy of the private citizens of Dunedin, who have not been sufficiently rewarded for the splendid asset which they have compelled the city councillors of Dunedin, much against their will, to accept. The moral is that city councillors should always deal with matters in a fair, honourable, and businesslike way. To play the game of bluff with other people's money is not one that will commend itself to anyone, but, as the Council has found out, does it pay in the long run?"

PROVISIONAL PATENTS, 1904.

DEC. 16.

27424. Device for magnetising iron by means of an alternate current and improvements in dynamo-electric machines. Miles Walker, 7, Skerton-road, Old Trafford, Manchester.

27434. Improvements in the construction of single and two-way electric switches. Clement Brown, Folke Olai, and Brown and Barlow, Limited, 16, Loveday-street, Birmingham.

27437. Improvements in and relating to arc lamps. Gustavus Martin Zingel, William Wolf, and Arthur Reiner, 72, Fenchurch-street, London.

27443. Improvements in electric arc lamps and carbons for same. August Eckstein and Arthur Ernest Angold, Peel Works, Adelphi, Salford, Manchester.

27444. Improvements in electric switches. August Eckstein and Albert Julius David Krause, Peel Works, Adelphi, Salford, Manchester.

27449. Method and apparatus for electrostatic separation. Wallace Fairweather, 65, Chancery-lane, London. (Charles Henry Huff, United States.) (Complete specification.)

Digitized by Google

27456. Electromagnetic ignition device for explosion engines. Friedrich Lutz, 65, Chancery-lane, London.

27475. Improvements in electrical switches. William Righter Comings, Wharncliffe, Wimbledon Park, London.

27479. Improvements in and relating to inverted arc electric lamps. Nicholas Pentreath Andrew and Thomas Macduff Mackelcan Johns, 55, Chancery-lane, London.

27537. Improvements in vapour electric apparatus. Howard Irving Wood, 83, Cannon-street, London. (Date applied for under Patents Act. 1901, Dec. 17, 1903, being date of application in United States.) (Complete specification.)

27538. Improvements in means for transforming electric current. Charles Proteus Steinmetz, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 17, 1903, being date of application in United States.) (Complete specification.)

DEC. 17.

27582. Improvement relating to clay ware, stone ware, and similar conduits for electrical cables. Horace Rendall Mansfield, Broom Leys, Coalville, near Leicester.

27605. Improved electric system of driving vehicles in an arena or course. Edward Ernest Lehwess, 111, Hatton-garden, London. (Complete specification.)

27627. Improvements in and relating to portable electric conductors. Arthur Bergtheil, 1, Queen Victoria-street, London.

27636. Improvements in and relating to electric systems of train lighting. The Allgemeine Elektricitäts-Gesellschaft, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 19, 1903, being date of application in Germany.) (Complete specification.)

27637. Improvements in and relating to vapour electric apparatus. John Thomas Henry Dempster, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 19, 1903, being date of application in United States.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Jan. 5, 1905.

1903.

20129. Mechanism for use in conjunction with apparatus for utilising electromagnetic or "Hertzian" waves. Smith.

21819. Automatically-operated telephonic exchanges for a small number of lines. Bullard.

22003. Conduits for electric cables or conductors. Devonshire.

22368. Means for generating intermittent electric currents for igniters of oil or gas engines and other purposes. Howorth. (Ryder.)

23604. Electric incandescent lamps. Riethof and Basch.

24102. Mountings and connections for electrical conductors, especially applicable to the supports for collecting brushes of dynamo-electric machines. Phœnix Dynamo Manufacturing Company, Limited, Oelschläger and Haddock.

24142. Electric interrupters or spark-gap apparatus for high-frequency currents. Johnson.

24343. Electric signs. Heinemann.

24394. Means for connecting electric circuits, especially applicable for the lamps of motorcars. Couverchel. (Date applied for under International Convention, Dec. 19, 1903.)

24560. Electric testing clip. Frankel. (Date applied for under International Convention, Dec. 2, 1903.)

24572. Electric igniters for internal-combustion engines. De Dion and Bouton. (Date applied for under International Convention, Aug. 16, 1904.)

24663. Electrical valve-controlling systems. Waterman.

24715. Incandescent gas and electric globe lamps. Lea and Perrins.

24722. Electric tramcars and the like and lifeguards or obstruction removers for use therewith. Whittaker.

24770. Electric signalling devices for elevators or the like. Imray. (Payne.)

Supplement to "The Electrical Engineer,"

JULY 8, 1904.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

703. In calculating the cable losses for a certain high-voltage long-distance polyphase transmission scheme with underground cables, an addition was made on account of "dielectric hysteresis." Can this be found in ergs per cubic centimetre as with magnetic hysteresis, and, if so, what are reliable figures for different classes of cable? In the vector diagram, should the current taken by this loss be plotted with the watt-current or the capacity-current? CEDILLA.

704. How would you calculate a blow-out magnet for a controller, given horse-power and voltage. Give the respective advantages and disadvantages of the different designs.—H. E.

705. What is the most practical method of preventing oil being thrown from the connecting rods and discs of horizontal engines running at 95 revolutions per minute, and having a 3ft. stroke. The engines are fitted with ordinary "Hood" splashguards, but these do not prevent the oil from being thrown out at the sides on to the floor and the frames of engine.—BARON.

ANSWERS.

Question No. 696.—It is stated that boilers fitted with superheaters (steam) should not take their feed through an injector. Why is this?

Best Answer to No. 696 (*awarded* 10*s.*).—The question is stated the wrong way about, there is no objection to feeding boilers fitted with superheaters by injectors, but there is a very great objection to using superheated steam to work an injector. The proper way to use injectors in such a case is to take steam for the injectors from the boiler side of the superheater. The objection to using superheated steam to work an injector is that so great a quantity of water would be necessary to condense the steam that the velocity of the steam is too much reduced in driving forward the large volume of water, and the steam is unable to force the water into the boiler. A consideration of the action of the injector will make this clear. The velocity of an issuing jet of steam is 16 to 18 times that of an issuing jet of water under the same pressure, and if steam while issuing from a boiler be condensed to water, but not reduced in velocity to that of water issuing under the same pressure, it is then able to overcome the pressure of the water in its own boiler. This is exactly what takes place in the injector. The steam enters the injector, and passing down the cone is condensed on coming into contact with the feed water (admitted a little below and on the opposite side to the steam), without losing its velocity further than that due to the friction of the passages. The vacuum formed in the injector by the condensation of the steam causes more water to rush into the injector, and this water is carried by the force of the condensed steam jet into the boiler. The velocity of the steam jet is of course reduced by imparting a high velocity to the volume of water, but provided the water is not too hot, or the steam superheated, the volume of water necessary to effect condensation is not great enough to reduce the velocity of the condensed steam jet to that of a jet of water issuing under the same pressure, and consequently it is able to overpower and drive back the water in the boiler. The feed water should not be hotter than 135deg. F. for low pressures and 105deg F. for the highest pressures. Taking the average cold feed water as being about 50deg., it will thus be apparent that a very small increase in temperature seriously affects the working of the injector, and, of course, this increase has the same effect whether due to hot feed water or to superheated steam, the effect being, as mentioned, to so increase the amount of water required for condensation as to reduce the velocity of the steam jet to such a point that it cannot overpower the water in the boiler. Obviously, if the injector has to lift its feed water the above troubles are accentuated.—W. T. W.

Answer to No. 696 (*awarded* 5*s.*).—There is no reason why injectors should not be used where superheaters are installed, unless it may be due to the following causes: In some types of injectors large quantities of air are drawn in, due to there being no non-return valve on the overflow. This air would mix with the feed water and be delivered to the boiler It would then pass with the steam through the superheater tubes, which might tend to become overheated, due to the poor heat-conducting properties of the air.—H. B.

Question No. 697.—How would you arrange and what materials would be most suitable in making-up a set of ambulance requisites for a central station?

Answer to No. 697 (*awarded* 10*s.*).—The most convenient arrangement for containing a set of ambulance requisites for a central station would be a glass-fronted cupboard, about 2ft. high by 2ft. wide, with one 10in. shelf spaced about 1ft. 3in. above the bottom of the cupboard. The door of the cupboard should be closed by a simple spring catch, to allow of it being quickly opened, without having to obtain a key. It should be fixed to the wall in any convenient dry place, where it will *always* be readily accessible, such as just inside an office, the door of which is never locked; and it is a special advantage if it can be close to a tap and lavatory basin.

The first part of the outfit should be contained in some form of havresack, so as to be portable complete, and should contain the following: 1 pair wooden splints (each made of two parts sliding in a metal sleeve, so as to be of adjustable length), 6 triangular bandages (which might be made by cutting diagonally three pieces of calico, each about 40in. square), 6 assorted roller bandages, ½lb. boric lint and ½lb. cotton wool in tin cases, 1 roll adhesive plaster, 1 piece linen tape, 1 pair scissors, 1 pair forceps, 1 knife, 2oz. bottle olive oil, 2oz. bottle tincture eucalyptus B.P.C., 2oz. bottle sal volatile, 2oz. bottle of ether comp., 1 graduated glass measure, 1 elastic band tourniquet, 1 small camel-hair brush, pins, needles, thread. A set containing most of these articles is supplied in a strong haversack by St. John's Ambulance Association, St. John's-gate, Clerkenwell, E.C., at the moderate cost of about £1. 12s.

In addition to this, the cupboard should also contain: 1 small basin and sponge, 1 drinking glass, 8oz sal volatile, 4oz. spirit ether comp., 4oz. tincture eucalyptus B.P.C., 1 flask olive oil, 1 small flask brandy, 4oz. tin bicarbonate soda, 4oz. tin powdered boric acid, 1 bottle strong smelling salts, 1 cake of carbolic soap.

The small pocket "Aide Memoir" and the handbook "First Aid to the Injured," both published by the St. John's Association at a total cost of 1s. 3d., should also be provided. The cost of the whole set of necessaries should not exceed about £2. 5s., excluding the cost of the cupboard. A reduction could be made if the liquids mentioned twice were included only in the haversack, but it is convenient to have a larger supply than that contained in small 2oz. bottles, as these particular liquids will be in fairly frequent demand for simple cuts, burns, scalds, etc.

Answer to No. 697 (*awarded* 10*s.*).—It is a strange and surprising fact that there are at the present day many central stations—large stations—that cannot boast of even

Digitized by Google

a bottle of carron oil within their walls. In all well-appointed manufacturing works, whether mechanical or electrical, special attention is always given to ambulance requirements. The same cannot, unfortunately, be said of the majority of central electricity stations. Quite recently the writer had brought to his notice a case of a labourer who had fallen from a scaffolding where some iron netting guards were being erected, and who was injured about the head and arms in a shocking manner. No ambulance dressings being available, the poor fellow remained in great pain until the arrival of the horse ambulance from the town fire station, the ambulance, fortunately, being in at the time. In the meantime, the only thing done to the poor fellow was the profuse application of engine cloths and waste, these, by the way, being none too sweet or clean. The unfortunate man's injuries were so serious as to necessitate his detention at the local hospital, where he remained for several weeks, and he will carry with him always ample evidence of the severity of his injuries. It is rather curious to note, by the way, that this man served through the Boer Campaign without receiving any injury. Another case which the writer witnessed was that of a stoker who had the misfortune to fall into a hot-feed tank, and was scalded very badly about the lower parts of his body. One member of the staff had the presence of mind to run to a house near by and obtain some flour and linseed oil, and the timely application of these was, no doubt, the means of saving the man much suffering. This case was rather unfortunate, as, owing to his being a new hand, the stoker had not had time to become a member of the work's sickness and accident club, and during the two months he was away he received no pay.

For a large station having 40 or 50 men in or about the works during the daytime, a complete litter and several ordinary stretchers are indispensable, as the charity and municipal ambulance stations should not be depended upon. This is more particularly so in the case of a large manufacturing town, where accidents requiring ambulance removal are of daily occurrence. The litter should be kept as near as possible to the road or street which offers the best and most convenient way to the nearest hospital. The stretchers could be kept in cupboards say, one or two convenient to the offices, and one in the engine-room. A case, containing an ample stock of dressings, etc., should be kept in the engine-room, preferably near to the main switchboard, and a good supply for restocking should be kept in the works' stores. It is not necessary to keep these necessaries under lock and key, as keys, not infrequently, have a nasty knack of being absent when most wanted. For moderate and small size stations perhaps a litter might be dispensed with, although advisable. A couple of stretchers and a case of dressings, arranged as in the above-mentioned case, would do.

In all stations, framed instruction sheets on "first aid" should be hung in prominent positions. The staff should be trained in the rendering of "first aid," and kept up to concert pitch by classes and demonstrations, from time to time, by a competent medico. The writer remembers a sad case of a labourer who was at work standing on a ladder only some few feet above the switchboard floor, falling, due to the ladder breaking, and injuring his head and back so severely as to render him quite unfit for any laborious work again. In this instance, the Corporation to whom the works belong were generous enough to give the unfortunate man an easy berth for the rest of his life. The nearest hospital was two miles away, no ambulance necessaries being kept at the station. Not very long ago the writer received a severe burn on the hand, together with a temporary partial blindness of the eyes, caused by the fusion of some switchgear connected to a faulty dynamo. In his case, also, there were no dressings at hand, and he had to run out (perspiring from a hot engine-room into the cold night air) to a chemist's shop some distance away, where the injuries were dressed. For a few nights following the eyes were so painful as to render sleep practically impossible.

The list given below is issued by the St. John Ambulance Association, St. John's-gate, Clerkenwell, London, E.C., from whom all articles mentioned therein may be obtained.

Litter complete, with ordinary stretcher and iron tyres to wheels, £11. 2s. 6d. and £12. 17s. 6d.; or with india-rubber tyres to wheels, £14. 7s. 6d. and £16. 2s. 6d.

Ordinary stretcher for general use, £1. 17s. 6d.

Telescopic-handled stretcher for working in confined places, £2. 5s.

Large hamper for ambulance station and railway purposes containing: 1 set of cane splints, 1 elastic band tourniquet, ½lb. carbolic cotton wool (in tin case), ½lb. boric lint, 1 roll adhesive plaster, 20 roller bandages (assorted), 1 dozen triangular bandages, 3 pieces tape, 4oz. sal volatile, 4oz. bicarbonate of soda, 4oz. olive oil, 4oz. spirit ether comp, ½lb. tin powdered boric acid, 4oz tincture eucalyptus B.P.C., 1 pair Pean's forceps, 1 pair scissors, 1 knife, 12 surgeon's needles, 1 packet each safety and plain pins, ½oz. carbolised Chinese twist, ½oz, silkworm gut, 1 reel each black and white sewing thread, 1 kidney-shaped basin, 1 stopper loosener, 1 graduated measure, 1 cake 20 per cent. carbolic soap, 1 nail brush, 3 empty 8oz. bottles. Price complete, £4.

Small ambulance hamper, with waterproof cover and strap, for use in factories, collieries, stations, and large works, containing 1 set splints, 1 elastic tourniquet, 3 tampons (for washing wounds), 2 packets lint, 4 roller bandages (wide and narrow), 4 triangular bandages, cotton and boric wool (in tin cases), spool of adhesive plaster, knife, scissors, thread, tape, needles, and pins. Weight complete, 6½lb. Price, £1. 11s. 6d.

First aid box for litter or ambulance station—can be placed on litter or hung up on a wall; a leather handle is also fitted for carrying purposes—containing 1 set wooden splints, 1 elastic band tourniquet, carbolic wool, boric lint (in tin cases), 1 roll adhesive plaster, 12 roller bandages (assorted), 6 triangular bandages, 3 pieces tape, 1 pair scissors, 1 knife, 1 kidney-shaped basin, 1 graduated measure, 2oz olive oil, 2oz tincture eucalyptus, B P.C., 2oz. sol volatile, 2oz spirits ether comp., 8oz. carron oil, pins (safety and plain), needles and thread. Price complete, £2. 10s.

The following list of books, etc., is recommended to those who take an interest in Red Cross work: "First Aid to the Injured," by J. Cantlie, M.B., F.R.C.S., 1s. "First Aid to the Injured" (six ambulance lectures), by Prof. F. Esmarch, 2s. Dr. G. H. Darwin's "First Aids," being a card to hang up, giving treatment of various accidents, 2d. "Emergency Book," for instantaneous reference, giving concise instructions, to hang on wall, 2s. 6d.—S. L.

Answer to No. 697 (*awarded* 10*s.*).—A very important function of the ambulance outfit is its relative position to the boiler and engine house of the central station. It is desirable to have it on the ground floor, and yet in as central a position as possible. In, I think, the majority of stations the boiler-house is on a lower level than the engine-room. If the difference of level is not very great I recommend that our ambulance outfit be placed in the engine-room. A cupboard should be purchased which will lock, and yet easily and quickly open when required. It should contain three shelves or divisions—one for medicines, one for instruments, cotton wool, towels, etc., and one for a large washing basin, soap, and nailbrush. This cupboard should be placed at a convenient height on the wall, and, if possible, near some warm-water service.

The necessary, or, at any rate, desirable materials to stock I will give you in list form: 1 magnetised needle, 1 set cane splints, 1 elastic band torniquet, ½lb. carbolic cotton wool, ½lb. boric lint, 1 roll adhesive plaister, 20 rolls bandages (assorted), 1 dozen triangular bandages, 3 rolls of tape, 1 bottle brandy, 1 bottle whiskey, 4oz. sal volatile, 8oz. glycerine and absolute phenol (50 per cent.), 4oz. bicarbonate of soda, 1 bottle Carron oil (equal parts of limewater and salad oil), ¼lb. tin powdered boric acid, 4oz tincture of eucalyptus, 1 pair Péone forceps, 1 pair medical scissors, 1 knife, 1 packet each safety and plain pins, 1 bottle Friar's Balsam, 1 bottle witch hazel, 1 sponge, 1 reel black and white cotton, 1 large enamelled basin, 1 stopper loosener, 2 soft towels, 2 cakes 20 per cent. carbolic soap, 1 nail brush, 1 stretcher.

Roughly I estimate the whole of this to cost £5, exclusive of the cabinet and stretcher. A stretcher, which perhaps is not absolutely necessary, but very desirable, would cost, say, £1. 10s. Far more important than all

Digitized by Google

this is some knowledge of "first aid to the injured," as of course all the above materials are valueless unless some members of the staff are aware of which to apply immediately an accident has occurred. The uses for a large number of items in the above list are obvious, so I propose to explain only the methods for treating the most likely and common accidents.

Burns.—First wash, and apply carron oil, then cover up the wound with tape over cotton wool. For the washing use Friar's Balsam and warm water.

Cuts.—An ordinary cut must simply be washed with a very weak solution of Friar's Balsam, and then bound up either with plaister alone, or cotton wool, and plaister and tape, according to the severity. More important is the case where an artery or vein is cut. Here it is absolutely necessary to stop the circulation immediately, else the patient will probably bleed to death. The circulation can be stopped by tying a bandage tightly round the limb; in the case of an artery, nearer the heart than the wound; in the case of a vein the reverse. It is very easy to see whether it is a vein or artery that is cut, as in the former the blood comes out slowly, and is dark in colour, whereas in the latter it spurts out, as it were, under great pressure, and is bright red in colour. If the cut is in the body where the circulation cannot be stopped by a bandage, your thumb must be applied, and held in position until medical aid is procured.

A Broken Limb.—Whether the fracture is compound or simple, the limb must be set in splints and temporarily bound up until a doctor can be brought; in the meantime the patient must be given a stimulant (brandy) and made as comfortable as possible.

Concussion.—Concussion of the brain is a common result of even small knocks, and the patient is usually very sick. This, again, is a case only for the doctor, but it is well to remember, above all, do not apply any stimulant.

Apoplectic Fits.—These fits often accompany concussion of the brain, but are sometimes brought about by excessive heat. Apply no stimulant, and allow the fit to take its course, taking care the patient does not hurt himself or bite his tongue.

Eye Troubles.—The magnetised needle mentioned above is to be used for extracting iron or steel splinters out of the eye. The needle only having to be placed over the splinter to attract it, and unless very deeply embedded, will extract it with very little pain.

Blood Poisoning.—This is caused generally by negligence in cleaning wounds before dressing them. If the wound is well cleaned and washed in warm water there is little chance of blood poisoning setting in. Friar's balsam I consider a much preferable disinfectant to "Iodoform," the latter having a very sickly and objectionable odour, and also making it impossible in many cases, on redressing the wound, to determine whether any festering has taken place.

Faint.—Whilst dressing wounds the patient very often goes faint. To prevent this, double up the patient; put his head between his knees for, say, one minute. A very great mistake made by many people is to sit their patient upright when in a faint, this being the worst treatment possible. A faint is due to the absence of blood in the head, and is, therefore, only cured by accelerating the flow of blood into that member of the body.

In conclusion, I should like to impress upon everyone the necessity for studying to some extent first aid, and to point out the number of lives lost, not only in central stations, but everywhere (even in the streets), solely through the deplorable ignorance of those about in even the very fundamental principles of first aid to the injured.—E. D. S. S.

Answer to No. 697 (*awarded 7s. 6d.*).—The best way to arrange this desirable idea is to communicate with the St. John's Ambulance Association, St. John's Gate, Clerkenwell, London, E.C., and to get a properly qualified man to attend and give the usual course of lectures. He would give about six lectures or lessons with practical illustrations, and at the end of about six or eight weeks a properly appointed examiner would attend and give certificates to the efficient members of the class. By this the men gain by the experience of others, and are brought up to date and in line with the best practice in "first aid." The instruction is good and definite and all can qualify easily if they give proper attention. My men have lately done this. The total cost to each man was about 4s. 6d. If the men on the station are not sufficiently numerous they can arrange with some neighbours to join the class, as there are many about who are eager to join as soon as they hear of the opportunity. This is by far the best mode of proceeding because it gives definite practical instruction and points out what must be avoided. The above-named cost includes 1s. for a most excellent little book, published by the St. John's Ambulance Association under the title of 'First Aid to the Injured," which should certainly be obtained in any case, whether the lectures are to be had or not, as it gives most valuable information in simple language. The latest edition is the best. In arranging a scheme of this sort it is very important to realise that the best of good intentions may fail in their object, simply through the want of proper instruction or through the want of knowing what to avoid. "First Aid" may be summarised as taking proper care of the patient while the doctor is being fetched. Unfortunately there is a tendency to avoid sending for a doctor, and there is a real danger in any officious, uninstructed person assuming the doctor's duties.

The materials most suitable to keep handy would be a roll of surgical lint, with a medium-sized pair of scissors to cut it, a few rolls of bandage, some non-poisonous disinfectant—*e.g.*, Rowan's or Jeyes'—an earthenware basin, and some warm water to wash dirt from a wound, about a pint of carron oil for burns, a reel or so of white cotton, and a suitable needle to fasten a bandage; and if serious accidents are feared, a stretcher and splints should be kept as illustrated in the little book on "First Aid." A blanket or rug to lay the patient on and keep him warm would also be advisable, and in the case of high-tension currents, insulating gloves and mats should be kept in definite easily accessible places, so that anybody may safely extricate the patient from his dangerous position. All the above must be kept scrupulously clean, and the book on "First Aid" gives very valuable instructions as to using them. A board of instructions should be hung on the wall, giving the address of the nearest doctor, and any other local instructions which may be necessary, such as where to stop steam or hot water, to shut off a dangerous current, etc. All the above should be put under the care of the most trustworthy man who has passed his examination in "first aid,' and is willing and anxious to undertake the responsibility which should be treated as an honour. This man should be able to take the lead, give directions, and prevent confusion. The most important thing to provide for is the necessary knowledge, for without it artificial respiration cannot be applied, serious bleeding cannot be stopped, and a patient with broken limbs cannot be moved safely.

To the above I would add that many accidents may be prevented by judicious forethought before starting any serious work, and by careful inspection while it is in progress—*e.g.*, provide that heavy weights cannot fall far unexpectedly, that ladders cannot slip, that chains are strong enough and have no faulty links, that earth is well timbered and cannot fall upon diggers, that hand-rails are provided on stairs and scaffolding, that no holes are left in the ground unprotected, that steam pipes and wires are joined to the sources of supply last instead of first, etc.—F. G. A.

Answer to No. 697 (*awarded 5s.*).—The following is a list of articles used at a large generating station in this city, which have in the past been very useful in cases of emergency—viz.: 1 16oz bottle carron oil, 1 12oz. bottle carbolic acid, 1 4oz. bottle Friar's balsam, 1 4oz. bottle tincture of steel, 1 4oz. bottle sal volatile, 1 4oz. jar boracic acid powder, 1lb. absorbent lint, 1lb. cotton wool, roller bandages ½in. to 2in. wide, 1 "Esmarch's" triangular bandages, 1 roll "Johnson's" adhesive plaster, 1 graduated glass, 1 pair scissors, 1 torniquet, 1 1s. edition of "First Aid to Injured," published by the St. John's Ambulance Association, London. All the above are contained in a box 18in. by 18in. by 10in., on the front of which is a label describing the various contents and their particular uses.—J. MUNGOVEN.

Question No. 698.—A certain mill is equipped with a 60-h.p. waterwheel of the "undershot" type. The mill is subjected to periodical shortages of water. It is proposed to provide a 50-h.p. induction motor of the single-phase type, the motor and waterwheel to be run in parallel on the shafting, it being assumed that the motor will automatically take up any excess of load as the waterwheel slows due to lack of water. During the winter months the shafting is occasionally but lightly loaded, and there being an excess of water at this period, is it possible for the waterwheel to drive the rotor of the motor above synchronous speed, and thus cause it to act as an "asynchronous generator," and return current to the line, causing variations in line pressure, etc.? If so, please describe methods of prevention.

Answer to No. 698 (*awarded* 10*s.*).—It is, of course, possible that the waterwheel would rise above synchronous speed, and in that case the induction motor would become a generator, and supply a certain amount of current to the line. The effect of this increased speed will, however, make no difference to the frequency, as the frequency depends entirely on the exciting current, which is obviously taken from the generators that have previously supplied current to the motor. In such a machine the effect of increasing the speed above synchronism is to make the rotor conductors cut the alternating field and set up a current in the rotor opposite in direction to when running as a motor. This current in the rotor will induce a current in the stator, which will also be opposite in direction, and thus the machine becomes a generator whose frequency is independent of its speed. It is not at all probable that such a contrivance would make much difference to the line voltage, especially if the plant supplying the power is greatly in excess of the power required for this particular motor. Further, such machines cannot deliver current to the circuit by increasing the speed above a certain point, unless the resistance of the circuit falls, for since the pressure at the stator terminals cannot rise above that of the line if the resistance of the external circuit be kept constant and the speed raised, the stator simply draws a greater wattless current.—E. AUSTIN.

NOTICES OF BOOKS.

Dynamo, Motor, and Switchboard Circuits, by W. R. BOWKER, published by Lockwood and Son; and **Practical Construction of Electric Tramways,** by W. R. BOWKER. Price, 6*s.* E. and F. N. Spon.

We may, perhaps, be allowed to call attention to these books because they are, in every sense of the word, elementary, and the author touches upon subjects which the ordinary text-book treats far more curtly. We think, however, that the time has long since passed when it is necessary to give a chapter in a book on tramways, merely describing the materials and equipment of various undertakings. The student is a student from many points of view. Many study a subject merely to pass an examination, and though that class must buy books, it does very little good otherwise. Another class, by far the more important, is trying to get information in order to utilise that information, the aim being to know what is best under certain conditions Hence, it would be far better to describe carefully the conditions which determine certain materials and equipment rather than to give that information without clearly describing why it was adopted. In both books the information given is fairly accurate, and most of it such as will prove useful. A very valuable feature is the number of illustrations, for in most cases the illustrations show clearly what no amount of words can explain so well. The definitions also are well put, and on the whole the books can be commended.

Transactions of the Junior Institution of Engineers. Vol. XIII. 1902-3. Edited by WALTER T. DUNN. 10*s.* 6*d.*

There are many methods of obtaining the latest information on practical subjects, but perhaps the most important of all is the attending the meetings of associations which deal with the specific subject under consideration. Owing to the great extension of knowledge during the past century, men have to specialise, but before they can do this it is necessary to generalise. Lord Brougham's dictum stands as good now as when it was uttered, and the most promising professional man is he who knows a little of everything and everything of one thing. We have watched with a considerable amount of interest the work and the growth of the Junior Engineers, and consider that they have advanced very rapidly year by year in perfection. The papers read at the meetings are mostly of an exceedingly interesting character, and as a rule are treated in an able way.

We have tried for many years past to impress upon the older and more experienced members of the profession that, so to speak, there are two ends to a professional career, the entry and the exit. Those who are entering the profession have all to learn; many of those who are leaving think there is nothing left for them to learn. The latter is a grave mistake, for he who ceases to learn ceases to be any good in this world. Considering then that those who are entering the profession have all to learn, while others have something to learn, it is not uninteresting or unuseful, but the contrary, to find subjects treated in a more or less elementary manner. Hence the great value of these junior institutions. Many of the papers are certainly of a students' type, while others as certainly appeal to the more experienced. The present volume of *Transactions* contains a number of papers which ought to appeal very strongly to all junior members of the engineering profession, and the papers are very diverse, as will be seen from the titles. Thus, we have "Marine Boilers," by Mr. Roundthwaite; a subject of exceptional interest in these days, when we are in a kind of transition state, hardly knowing what kind of boilers to put in either in the Navy or in the more peaceful ships. We want the best, but they must be the best under all conditions, not under particular conditions. Besides the paper by Mr. Roundthwaite, Mr. Yarrow deals with certain trials in certain water-tube boilers, while Mr. Paterson deals with greasy condensing water as boiler feed.

Then, almost as important is the question of fuel, and Mr. Wernham discusses the "Calorimetry of Gaseous Fuels." Electrical engineering has its place in a paper by Mr. George on "Electric Motors for Factory Work," and a paper of another character which appeals strongly to an enormous number of students is that on the "Effect of Design on Methods of Construction from a Contractor's Point of View," by Mr. Newman.

There is a mass of other information in the volume, but we have said enough to show that certainly this volume is at least the equal, and, we believe, the superior of any other preceding it.

Law of the Telegraph, Telephone, and Submarine Cable. By E. G. M. CARMICHAEL. Knight and Co.

The law relating to telegraphy is practically modern, as will be seen from the following. The year 1836 saw the grant of letters patent to Messrs. Cook and Wheatstone for a certain invention described as "improvements in giving signals and sounding alarums in distant places by means of electric currents transmitted through metallic currents." Subsidiary patents were from time to time granted to inventors throughout the United Kingdom up to 1845. So far as regards telegraphy and telephony, it has been legally held that the latter is a branch of the former. Unfortunately, we have in this kingdom conflicting interests, and the law relating to the subject must necessarily be closely considered during any attempt to get rid of the opposition parties. The question of the submarine cable may also become a delicate one in the face of aerial telegraphy. The latter, being a newcomer, finds legislative enactment, some of which may have to be changed before it can gain a free hand. This book will assist those who desire to learn the law on the subject.

Supplement to "The Electrical Engineer,"
JULY 15, 1904.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

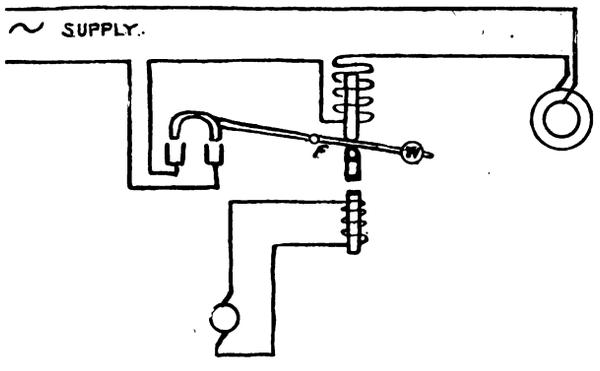
706. In testing a six-pole, 200-kw., 500-volt machine for a faulty (?) armature coil, the following methods were adopted: The brush leads were connected together, with an ammeter in circuit, and the field was separately excited off the 'bus bars, in series with incandescent lamps, with a current of ·6 ampere. The machine was run at about half speed (200 to 230 revolutions per minute), and a current of 400 to 600 amperes was maintained. When the machine slowed up with any drop in steam pressure the amperage rose. The lamps in series with the field continually waxed and waned whilst the machine was running, and in switching off these lamps at the end of the run, the last one switched off, thereby breaking the field circuit, became intensely luminous at the instant of switching off. Explain these phenomena.—A.

707. Describe the process of determining the permeability of a specimen of iron in the shape of an anchor ring for a given magnetising force.—VINCENT.

ANSWERS.

[The following answer was inadvertently omitted from our last issue.—ED. *E. E.*]

Answer to No. 698 (*awarded* 10*s.*).—A method as shown in the accompanying sketch will be found to give satisfactory results. One of the mains to induction motor passes round a laminated core, the core being fastened to a lever which works rounds the fulcrum, F. One end of this lever carries an adjustable weight, W, the other a U-piece of copper to make and break connection with the two mercury-cups. Below the lever is another solenoid, the core of which acts on a piece of iron fixed to underside of lever. This lower solenoid is energised from a small direct-current dynamo, which is driven from the axis of the water-wheel. The arrangement is therefore differential.



Suppose the waterwheel and motor are running together, and that, owing to extra flow of water or reduction in load, there is an increase in the number of revolutions of the combination per minute. It is a property of the induction motor that as the speed of the rotor increases the current falls off, owing to the reduction in "slip." Consequently, as the speed of the combination increases the current drawn from supply mains decreases. The solenoid in the alternating-current circuit may then be adjusted by means of the weight, W, to cut the motor out of circuit at any desired speed. Unless sufficient current is passing, the pull of solenoid will not be enough to keep the copper U-piece in the mercury-cups. The water wheel may now be considered to be taking all the load with the motor cut out of circuit. Should occasion arise for help from the motor, the lower solenoid becomes weaker, and allows the lever to fall over and close the motor circuit. The fall in speed of water wheel causes a proportionate drop in volts of the direct-current dynamo, and, therefore, a weaker current round the lower solenoid. If thought desirable, both cores could be attached to the lever, but it is generally advisable to make moving parts of such apparatus as light as possible. With this arrangement there need be no fear as to the motor acting as a generator.—M. M.

Question No. 699.—Show how to determine the percentage of oil in exhaust steam, samples of steam being taken from the inlet and outlet branches of an exhaust steam oil separator.

Best Answer to No. 699 (*awarded* 10*s.*).—To determine with any degree of accuracy the percentage of oil in the exhaust steam, it is first necessary to condense the steam. Certain precautions must, therefore, be taken to ensure that in the condensation the whole of the oil contained in the steam is left, so to speak, in the water, and that a fair sample of the steam is obtained. In the subjoined sketch (Fig. 1) S represents a steam separator with inlet on top

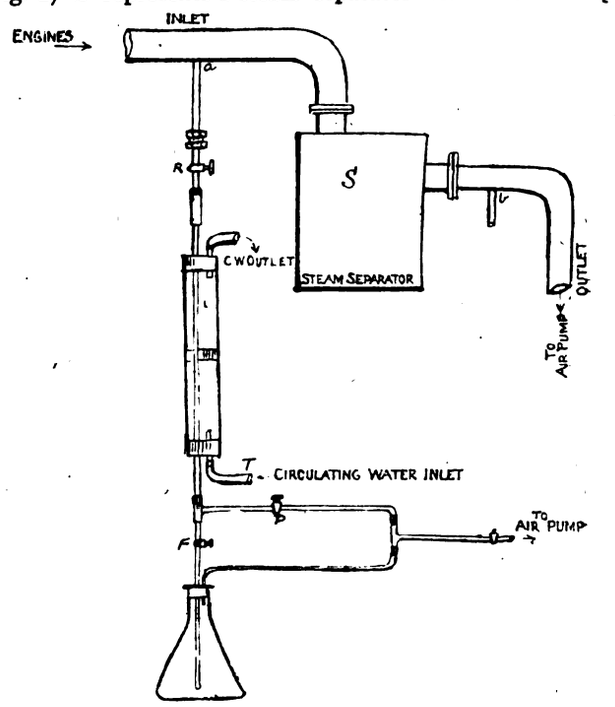


FIG. 1.

and outlet at the side. In the horizontal limb (preferably) at the points *a* in the inlet and *b* in the outlet a ⅜in. hole may be tapped, and a copper or iron tube screwed in so that the tube may be moved vertically across the section of the pipe. The sketch shows the arrangement for the inlet pipe, and it will be seen that the ⅜in. pipe is connected, through a stopcock, to a condenser—one of glass is quite good enough—consisting of two concentric glass tubes, through the outer of which water may be circulated. The inner tube is connected to the ⅜in. pipe, and is carried down into a glass flask. If the engines cannot be run on the atmosphere, through the separator, the inner tube should run close to the bottom of the flask, which should be corked and a small tube connected to some convenient part of the system under vacuum—maybe to the air-pump inlet. To ensure a fair sample, steam must be allowed to flow through the tubes for some time; the method of doing this is shown, for by shutting the cock F and opening P and R steam flows direct down the ⅜in. pipe through the inner tube of the condenser and along the branch through P to the air-pump or atmosphere. The circulating water should then be run through the outer tube—the town supply connected to the bottom inlet, T, will serve well—the cock, P, shut and F opened. The condensed steam collects in the flask, and by screwing the ⅜in. tube up and down a very fair sample of steam is

Digitized by Google

obtained. About half a pint of water should be collected. To estimate the oil, pour about 100 cubic centimetres (·176 pint) of the condensed water into a shaking flask (Fig. 2) of about quarter-pint capacity, and pour in about five cubic centimetres of ether. Shake up well, and allow to stand for a minute. Pour in another five cubic centimetres of ether, and repeat the operation. The ether dissolves the oil and separates off from the water. Probably about 25 cubic centimetres of ether will suffice to dissolve out all the oil quickly, and after settling, the water should be tapped off into another shaking flask, 10 cubic centimetres more of ether added to it, and separated as before.

FIG. 2.

The two ethereal solutions should be mixed into a weighed flask and the ether distilled off, either through a Liebig condenser, or, if the accuracy of the result is not required to be absolute, over a water-bath. The residue must be carefully dried and weighed, the difference between the weights of the flask giving the weight of oil in 100 grm. of water, and thus the percentage sought. A sample must also be taken from *b*, and thus the required percentages of oil in inlet and outlet found.—S. E. T.

Answer to No. 699 (*awarded* 7*s.* 6*d.*).—This is not a very simple matter. Different classes of grease and oil are used for lubricating pistons, and these different classes behave differently—*e.g.*, vegetable or animal grease would be decomposed by the hot steam, and so (I have found) are also some of the so-called mineral oils with steam of 50lb. pressure, although, of course, pure mineral oils would not be. Some time ago I put an iron plate about 3ft. square in front of the exhaust pipe of a steam-engine, so that the steam, etc., had to go through about 3ft. to 4ft. of air before impinging upon the surface of the iron plate. The result was instructive, for the plate became covered with a thick coating of grease from the cylinders even when fair quality black cylinder oil (mineral) was used exclusively in the engines, and although all the oil was liquid enough to pass when cold through sight-feed lubricators drop by drop. The grease was very adhesive and remained sticking to the plate for weeks. This simple experiment makes me think that merely taking a sample of steam from the side of the exhaust pipe would either give no result at all or else be misleading. I would, therefore, advise that the best way to ascertain the percentage of grease in the exhaust steam would be to run the machinery as usual but to note the amount of steam condensed, and then to draw off the oil from the separator, when the ratio of one to the other would give the percentage of oil or grease in the exhaust steam either by weight or measure as desired. Another method would be to note the amount of oil put into the cylinders, and to note the amount of exhaust steam condensed, when the ratio of the weight of oil used and weight of water condensed would give the percentage of oil in the exhaust steam almost exactly, because it is obvious that as no grease accumulates in the cylinders and none drops from the piston rod and gland, it must all pass out except the very small amount which is usually found inside the cylinders and steam-chest, but which amounts to practically nothing. In this last method no allowance would have to be made for decomposition of the vegetable or animal fat which might be present.

If it is really necessary to ascertain the percentage of grease in the exhaust steam—*i.e.*, incorporated with the steam—then a specially constructed exhaust box must be provided so that the steam blows straight against a baffle plate, which stands up from the bottom of the box, and allows any lumps of grease passing out with the steam to trickle down its surface and lie quietly and safely at the bottom of the box out of the way of the steam. This baffle plate should be corrugated vertically, so that grease when once on it cannot be blown off again by the passing steam. The exit of the steam would be past the two sides and over the top of this corrugated baffle plate, and so out at a hole in the middle of the opposite side of the box into a pipe, which should be surrounded with cold water like a Liebig's condenser, and long enough to condense all the steam to water, which must be caught in a tank and allowed time to settle, when the grease actually incorporated with the steam would be found floating on the surface of the water, and could be collected and measured or weighed. The oil collected by the corrugated baffle plate would be allowed to run out by the opening of a tap placed at the bottom of the oil-well, and would show the quantity and quality of the grease blown out in drops or lumps, and would probably be considered grease used in excess of actual requirements, if not entirely, at least in large proportion; but this would have to be considered with reference to local circumstances, such as steam pressure and the quality of oil used. Some oil merchants say that the oil is "atomised" and passes along the pipes—*i.e.*, incorporated with the steam—but I am not disposed to believe this statement, at all events, in the case of vegetable, animal, and the heavy mineral oils used in steam-cylinders. I would rather say that the heat renders the heavy mineral oil very liquid and mobile, and consequently greatly facilitates its already great capillary or creeping action. The vegetable and animal oils would be decomposed into glycerine and a fatty acid by the action of much heated steam.—F. G. A.

Question No. 700.—In an engine which is governed by a throttle valve, does the loss of pressure in the valve represent a *corresponding* loss of efficiency in the engine? In other words, would the heat generated by the fluid friction in the valve (which heat would presumably be carried forward by the steam) be to any extent converted into useful work in the engine?

Answer to No. 700 (*awarded* 10*s.*).—This question appears to be one which must be approached cautiously, or it might easily be misunderstood. In fact, several constructions could be put on the wording of the question. When I read the first part of the question, I immediately had in my mind's eye a comparison between an engine fitted with a throttle governor and the same engine fitted with an automatic cut-off governor. Looking at it from this point of view, I should have no hesitation in saying that, theoretically, the engine when fitted with an automatic cut-off governor should be more economical than when fitted with a throttle-valve governor; but when I finished reading the question it seemed to bring other conditions into consideration—in fact, conditions seldom met in practice.

Let us take an engine in our mind's eye, and follow the steam through the various stages. First, when fitted with an automatic cut-off governor, the steam would be admitted to the valve chest at boiler pressure (neglecting losses in connections) and, providing it does not pass through a superheater, would be ordinary saturated steam. This steam is carried at initial pressure until the point of cut-off, when it is expanded to the extent desirable. This would, of course, be our ideal of practical efficiency. But let us now follow the steam when the engine is fitted with a throttle governor. The condition of the steam at full load would be similar to that in the first case, but at light loads the throttle valve would be partly closed, so that the steam would be wire-drawn and supplied to the slide valve at a reduced pressure. Now consider the state of the steam under these varying conditions. Two cases must be taken for this purpose—first, when the engine is working on light loads for very long periods; second, when the intervals on light loads occur frequently and are of short duration. Taking the latter case, the conditions would be as follows: Steam would be supplied at the slide valve alternately with high and low pressures and temperatures, consequently the average temperature of the valve casing would be something between the highest and lowest temperatures of the steam admitted. The effect of this would be that when on full load condensation would take place between the throttle and slide valves, and when on light loads superheating would take place. If full load working is of shorter duration than light-load, there would be more condensation than superheating taking place; on the other hand, if light-load working be of shorter duration than full-load working, more superheating will take place, so that we see on light loads we should have, instead of "fluid friction," what we might term "superheat friction."

Taking the other case, with very long periods on light load, there would be considerable condensation taking place

Digitized by Google

due to the change in pressure, and, consequently, temperature, and here we should get "fluid friction," and the question now is, "Would the heat generated by the fluid friction in the valve (which heat would presumably be carried forward by the steam) be to any extent converted into useful work in the engine?" My answer to this question is, "No."

If I admit that fluid due to condensation by reason of the use of the throttle valve caused additional friction, and put more work on the valve rods, additional work must be done by the piston to overcome this friction, and the heat generated by reason of friction cannot be again converted into work without loss, therefore it is not possible for useful work to be got out of any engine by reason of the heat generated by friction of any kind. Personally, I am of opinion that moisture in the steam reduces friction. I have run triple-expansion engines of 6,000 h.p., month in and month out, without putting a drop of oil in the cylinders, except that which crept in when swabing the rods, depending entirely on the saturated steam for lubrication.—A. C.

Answer to No. 700 (*awarded* 10*s.*).—When steam is wire-drawn in passing through a throttle valve, the steam expands without doing useful work; its expansive energy is then mostly employed in increasing the velocity of the steam particles. The kinetic energy so produced will ultimately be transformed to heat by fluid friction in the steam. This heat will, if the steam originally contained moisture, evaporate some, or all, of it, and perhaps superheat the steam. The useful work obtainable from the steam is less after this unbalanced expansion than before, but the resulting loss is less than the direct loss due to fall in pressure. Thus if steam, in passing through the valve, has its pressure reduced by d P, and the mean specific volume be V, loss in thermal units per pound of steam will be $\frac{d\,P\,V}{5{\cdot}36}$. For example: If dry steam fall in pressure from 100lb. to 90lb. per square inch, taking the mean specific volume as 4·39 cubic feet, the loss

$$= \frac{10 \times 4{\cdot}39}{5{\cdot}36} = 8{\cdot}1 \text{ thermal units.}$$

The loss due to wire-drawing—the engine in which the steam does work being otherwise perfect—will be given by the formula

$$T_0 \left(\frac{1}{T_2} - \frac{1}{T_1}\right) L_1,$$

where T_1, T_2, T_0 are the absolute temperatures of the steam at 100lb., 90lb., and exhaust respectively, and L_1 the latent heat of the steam at temperature T_1. The loss in this case, therefore,

$$= 563 \left(\frac{1}{781} - \frac{1}{789}\right) 883{\cdot}6 = 6{\cdot}4 \text{ thermal units,}$$

T_0 being taken as 563, or 102deg. F. The difference between the two results, of 1·7 units, is due to the drying or superheating effect of wire-drawing.

The formulæ from which the foregoing results are deduced are based on certain assumptions not realised in practice. The steam does work in an engine supposed to be perfect, except for the wire-drawing of the steam from 100lb. to 90lb., all the heat generated by friction against the valve being supposed to pass into the steam. If the valve be raised to a higher temperature than the metal forming the casing, heat will be conducted from the valve to the latter. The temperature to which the valve is raised depends upon the relative rates at which heat is generated in, and given up by, the valve, the last depending upon the state of the steam as regards dryness and temperature, and also the flow of steam over the heated surface. It is not improbable, therefore, in practice that some of the heat generated in the valve is lost, and the remainder given up to the steam.

In reference to the value of the heat passed to the steam from the valve, as regards its bearing on engine efficiency, the maximum work obtainable from it will depend upon the temperature of the steam that receives it. Although a quantity of heat has a mechanical equivalent, its mechanical value depends upon the temperatures between which it may be utilised. Suppose that each pound of the steam, absolute temperature T_1, supplied to an engine (in which the only imperfection is wire-drawing) loses a quantity of heat, K, in friction against the valve, and that this quantity is passed to the steam back from the valve at temperature T_2, corresponding to the reduced pressure. Then, if T_0 be the exhaust temperature, the greatest amount of work obtainable from K at the initial pressure will be

$$K \frac{T_1 - T_0}{T_1} \text{ thermal units;}$$

and at the reduced pressure

$$K \frac{T_2 - T_0}{T_2} \text{ thermal units.}$$

In the case above the first will be

$$K \frac{789 - 563}{789} = {\cdot}286\ K,$$

and the last $$K \frac{781 - 563}{781} = {\cdot}279\ K.$$

Thus the loss is ·007 K thermal units, whereas if the heat, K, were not returned to the steam, the loss per pound of steam would be ·279 K for an engine working between the absolute temperatures 789deg. and 563deg.—H. J. W.

Answer to No. 700 (*awarded* 10*s.*).—This question may be best answered by dealing with a particular case and estimating the comparative economy. Before doing so it will be as well to recall Prof Peabody's throttling calorimeter, which within its limits is known to give accurate results. As the name implies, the steam to be tested for dryness is throttled at its inlet to the calorimeter and the pressure reduced to nearly atmospheric pressure. The heat units represented by the difference in the total heat of the steam at the higher and lower pressure, are then available at the calorimeter to first re-evaporate any moisture in the steam and then to superheat it, or, if, as is very unlikely, the steam is dry, the heat units would be expended in superheating alone. Now, the use of this calorimeter is one instance of throttling through an exceptional range, and, if, as the question suggests, fluid friction resulted in the production of heat at the throttle valves, its effect would be noticeable. It has, however, been found actually that the superheating effect is only that to be expected from the heat units liberated by the fall in pressure and no more, and, as a result, the use of this calorimeter is limited to cases in which the steam is dry enough to allow some superheating to be observed. Steam containing more than 3 per cent. of water does not liberate sufficient heat to do more than re-evaporate moisture, unless the degree of throttling or the fall of pressure is such as to be beyond practical working conditions. As an actual example of the loss due to throttling the following case may be stated. Steam pressure at the engine, 145lb., supplied in the first instance to the engine steam-chest at this pressure, and in the second instance at 125lb. gauge pressure, or throttle reduced 20lb. The engines tested under these conditions at full load showed steam consumptions of 22lb. and 25lb. per indicated horse-power hour respectively, or a difference of 12 per cent. The engines were of precisely the same design, the difference between them consisting alone in the use of suitable cylinders and points of cut-off at the valves to allow the same powers to be developed at the different pressures stated. As there are essential differences in any particular type of engine, the 12 per cent. economy may be taken as representing the practical gain, which might be a little more or less in other engines of different size and construction. As it is comparative economy that is being considered, it is, of course, necessary that results from the same design and size of engine should be given. Considered from the standpoint of absolute thermal efficiency the gain would be 7½ per cent., but there are so many conflicting conditions that modify the theoretical conceptions that space will not permit of its being entered into here. The "drying action" at the throttle valve is inseparable from throttling, but its probable effect may be calculated in the following way. Taking the total heats of the steam at the same pressures as already considered, the difference is 1,192·8 −1,189·5 = 3·3 heat units. The specific heat of steam at constant pressure is, according to Regnault, 0·4805, and the same authority gives the same figure for superheated

Digitized by Google

steam. Hence the 3·3 heat units would be capable of superheating dry steam 3·3 ÷ 0·4805 = 6 86deg. F. This degree of superheat would not result in more than 1½ per cent. gain in economy—that is, the gain in economy by using steam at 145lb. pressure, throttled to 125, would not be more than 1½ per cent.—assuming that the steam is dry saturated steam before throttling, and as compared with the same quality of steam used without throttling, and supplied at 125lb. pressure.—E. G. B.

Answer to No. 700 (*awarded* 10*s.*).—In the various experiments which have been conducted from time to time, the method of governing an engine by a throttle valve does not seem the most efficient. In considering this question, it is necessary to look up the law of expansion of gases, which is: "That if a gas expands without doing external work, there is no loss of molecular efficiency." Now, seeing that the throttle valve has the effect of reducing the pressure of the steam, there must necessarily be (under ordinary conditions) a corresponding increase in volume and a reduction in temperature. Now, assuming that the molecular action on the valve face has the effect of slightly increasing the temperature of the steam, it is quite clear that this is attained at the expense of the kinetic energy or velocity of the steam, so that it is reasonable to assume that there would be no loss of efficiency due to the change of form of effects. We can see, then, that the effect of reducing the pressure of the steam means a corresponding increase in volume but with a reduction in temperature, and simply means that the engine would require a larger volume of steam than it would require if the pressure was higher.

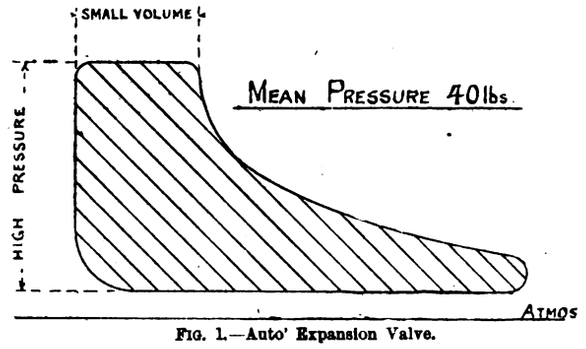

FIG. 1.—Auto' Expansion Valve.

In Figs. 1 and 2 are shown indicator diagrams, taken off similar engines and working under similar loads. Fig. 1 shows the effects which are produced when the engine is controlled by an automatic expansion valve, which varies the amount of cut-off. The boiler pressure is maintained in the cylinder, and the expansion is varied according to the load. Fig. 2 shows the effects which are produced

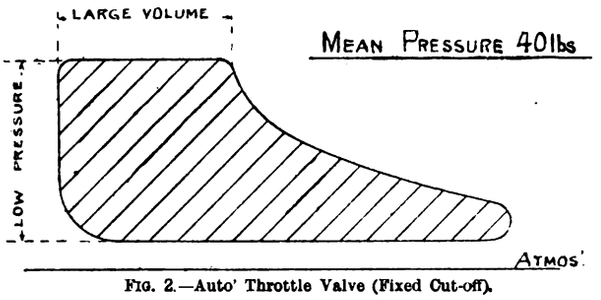

FIG. 2.—Auto' Throttle Valve (Fixed Cut-off).

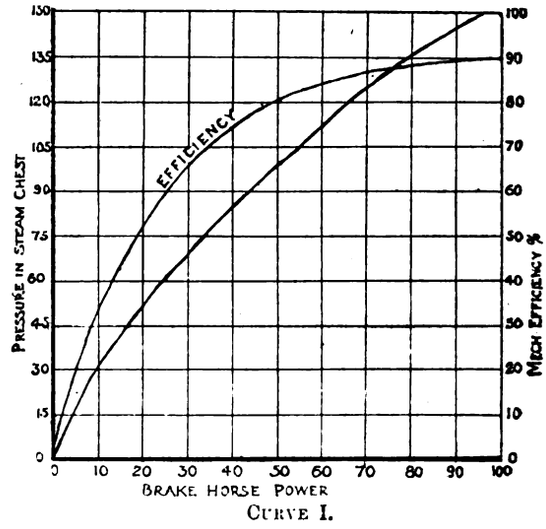
when the engine is governed by a throttle valve. The expansion is fixed, but the throttle valve varies the pressure of the steam according to the load applied. The same mean effective pressure is obtained in both cases, and are simply different methods of obtaining the same end. In Fig. 1 there is a higher pressure of steam with a small volume. In Fig. 2 there is a lower pressure of steam, but with a large volume. Thus, there is no reason to assume that because the steam has suffered a drop in pressure that there is a corresponding loss in efficiency—what it loses in pressure it gains in volume. The pressure, volume, and temperature of steam is determined by a certain law, and should any one of these be affected it must of necessity affect each of the others.

If it is reasonable to assume that heat is generated by fluid friction in the valve, it is clear that this must have the effect of increasing either the pressure of the steam, if the volume is kept constant, or increasing the volume if the pressure is kept constant, but this effect could not be distinguished from the ordinary effects which accompany steam.

To sum up, there does not appear to be any reason why there should be a decrease in the efficiency of the steam because of the throttling effect. In other words, the gas being self-contained, an alteration in the form of effects does not make any difference in the intrinsic value. It might be well to quote the well-known "law of Charles" for steam, which is: "Under constant pressure equal volume of different gases expand equally for the same increment of temperature, and the volume changes proportionally to the absolute temperature."—JAMES W. TUNSTALL.

Answer to No. 700 (*awarded* 7*s.* 6*d.*).—In an engine governed by a throttle valve, the loss of pressure in the valve does not represent a corresponding loss of efficiency in the engine. When the efficiency of an engine is spoken of, the mechanical efficiency is usually meant—*i.e.*, the ratio of brake horse-power to indicated horse-power. That this ratio does not decrease at the same rate as the steam pressure is made clear in taking a practical case. Suppose the efficiency of a 100-b.h.p. engine at full load with 150lb. steam pressure is 90 per cent., and at half load 80 per cent., and that there is no throttling at full load and 90lb. initial pressure at half load. Now the steam pressure has dropped 60 per cent, and if there was a corresponding drop in the mechanical efficiency this would be only 54 per cent., whereas it is really 80 per cent. The mechanical efficiency of an engine, of course, falls with the load, until at no load it becomes zero; but it does not correspond in any way with the loss of pressure in the valve, as will be seen by Curve I. If it did, the curves would be parallel with each other.



CURVE I.

As regards the heat generated by the fluid friction in the valve, this is of some account in raising the *thermal* efficiency of an engine and in counteracting the causes tending to lower it at light load—for instance, the greater initial condensation due to the lower temperature of the throttled steam. That it has some effect is proved by the Willans straight-line law, which is that in an engine governed by a throttle valve with fixed cut-off the curve of steam consumption per hour and indicated horse-power, when plotted on squared paper, lie in a straight line. A throttle valve has the effect of drying and, under favourable conditions, slightly superheating the steam.—A. B. S.

[Other replies to Question No. 700 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

QUESTIONS.

708. On a four-pole, 200-ampere, 500-volt B.T.H. three-phase rotary converter, the attendant when running the machine up as a direct-current motor left the shunt field switch open, and machine ran up as a series motor, but in the opposite direction to that in which it runs as a shunt machine. Are the shunt and series windings connected up properly? If not, what is the best method to find out which way the coils are wound without uncovering the windings, and how should they be connected up? P.S.—The shunt coils are joined up two in series.—HERIONS.

709. The proprietors of a boarding-house have a small hand-worked lift for elevating and bringing down dinners, etc. It is desired to work the lift electrically. What would be the best method of doing so, so as to obtain the following conditions: The switching gear must be of the simplest, and be easily understood by the servants, and, of course, be fool-proof. It must be actuated from either top or bottom. The lift is balanced, and it is required to take up at full load about 1cwt. of utensils, etc.; silent working is specially desired. Capital cost to be kept as low as possible. Skilled labour is available to do the whole of the erecting and wiring, but not to supervise after the job has been set to work. A supply of energy at 230 volts is available, and there is an electric bell service from top to bottom of lift.—W. T. W.

710. Controller required for a three-phase motor, 6 h.p., 100 volts; ratio of turns, 2:3; periodicity, 60. Work out diagram of connections and main dimensions of controller, supposing it were for lifting purposes on a crane.—H. E.

ANSWERS.

Question No. 709.—In an engine which is governed by a throttle valve, does the loss of pressure in the valve represent a *corresponding* loss of efficiency in the engine? In other words, would the heat generated by the fluid friction in the valve (which heat would presumably be carried forward by the steam) be to any extent converted into useful work in the engine?

Answer to No. 700 (*awarded 7s. 6d.*).—To govern an engine by means of a throttle valve is inefficient by reason of reducing the pressure. High-pressure steam, as is well known, contains very little more heat than steam at low pressures; but its expansive properties being far superior, it is obviously economical to work at high pressure at all loads, and regulate by altering the cut-off. Taking steam at 200lb. per square inch absolute and applying Regnault's formula to find the total heat, we have $1{,}082 + {\cdot}3\,t$, where t is the temperature of the steam; $1{,}082 + {\cdot}3 \times 381{\cdot}8 = 1{,}196{\cdot}5$ British thermal units. Now, suppose this steam to be throttled, so that its pressure falls to 100lb. per square inch. Applying the above formula, we have $1{,}082 + {\cdot}3 \times 327{\cdot}7 = 1{,}180$ British thermal units. Thus it will be seen that although the pressure has been reduced to one-half, the loss in British thermal units is only about 1½ per cent. of the original number. If, however, we come to compare the work done by a given weight of steam at these pressures, it will be found that by taking advantage of the expansive properties of the high-pressure steam we can obtain a considerable increase in efficiency. This may be proved by drawing a theoretical diagram for each of the pressures, with cut-off taking place at that part of the stroke that will allow the steam to expand down to the back pressure. This point can be found by

$$\frac{\text{Initial pressure}}{\text{Total back pressure}}.$$

Another easier method, although perhaps not quite so convincing, is to find the mean theoretical effective pressure by the formula

$$\text{M.E.P.} = \frac{P_1 + \text{hyp. log } R}{R} - \text{back pressure},$$

where P = initial pressure,
R = range of expansion.

Taking the first case, with steam at 200lb. per square inch absolute, and a back pressure of 17lb., and for convenience we will assume that it is expanded down to 20lb. per square inch, so that the number of expansions is 10. Applying the above formula,

$$\text{M.E.P.} = \frac{200 \times 1 + 3\,302}{10} - 17 = 49\text{lb.}$$

Again applying the formula to the low-pressure steam, in this case the number of expansions will be $\frac{100}{20} = 5$.

$$\text{M.E.P.} = \frac{100 \times 1 + 1\,6}{5} - 17 = 35\text{lb.}$$

From this calculation it will be seen that although only half the volume is used per stroke in the case of the high-pressure steam, yet the mean effective pressure is 14lb. per square inch more. But to compare the efficiency it is necessary to know the weight of steam used per stroke. Now, the weight of steam varies approximately as the pressure—that is to say, that a cubic foot of steam at 200lb. per square inch will have, roughly, twice the weight of a cubic foot at 100lb. Therefore, since there is twice the volume used when working with the low pressure, the weight used per stroke may be taken as the same, and the increase in efficiency will be due to the increase in the mean effective pressure, which is 14 per cent. greater than the original pressure. Hence the loss in a steam-engine due to governing with a throttle valve is brought about by not taking advantage of the expansive properties of the high-pressure steam, and the heat lost by the reduction of pressure is really a minor quantity, and cannot be called upon to compensate to any great extent for the loss. Turning now to the question which asks would the heat generated by the fluid friction be to any extent converted into useful work in the engine, the answer is obviously only to a very small extent, for it is well known that if steam passes through a throttle valve it becomes heated and consequently drier, and if the steam contains little moisture it becomes superheated. Hence cylinder condensation will be reduced and efficiency increased, but, as already explained, only slightly. E. AUSTIN.

Answer to No. 700 (*awarded 7s. 6d.*).—Bearing in mind the fact that no heat is lost in passing steam through a valve, then the total heat on one side of the valve is equal to the total heat on the other side, and the heat generated by the fluid friction will go towards converting some of the saturated steam into dry steam, or, expressed in another way, in improving the dryness of the steam, and is given by the following equation:

$$S_1 + x_1 L_1 = S_2 + x_2 L_2,$$

where S = sensible heat, L = latent heat, and x the dryness fraction of the steam.

Taking the corresponding temperatures of the two pressures—*i.e.*, before and after throttling—as T_1 and T_2, then

$$S_1 + x_1 L_1 = (T_1 - 32) + x_1 \{966{\cdot}6 - {\cdot}7(T_1 - 212)\}$$

and $$S_2 + x_2 L_2 = (T_2 - 32) + x_2 \{966{\cdot}6 - {\cdot}7(T_2 - 212)\}.$$

For example, take steam at 160lb. per square inch absolute pressure, and dryness fraction ·9, reduced to 100lb. per square inch. Their respective temperatures are 363·3deg. F. and 327·6deg. F. Then

$$(363{\cdot}3 - 32) + {\cdot}9\,\{966{\cdot}6 - {\cdot}7\,(363\,3 - 212)\} = (327\,6 - 32) - x\,\{327{\cdot}6 - {\cdot}7\,(327{\cdot}6 - 212)\}.$$

$$\therefore\ x = {\cdot}915,$$

being an increase in dryness of 1·5 per cent.

By increasing the dryness fraction, a greater proportion of the steam is in the form of dry steam and less in the form of moisture, and so there is more dry steam per pound of feed after reduction of pressure than before, and therefore the drop in efficiency in the engine is more gradual than the drop in pressure.

If the steam is dry to commence with, then the effect of reducing its pressure will be to add heat to it, which will increase its temperature above the normal at that pressure, and this will lessen the amount of cylinder condensation there would be with the throttle valve open.—E. L.

Answer to No. 700 (*awarded 5s.*).—There are two general methods of governing steam-engines: by varying

Digitized by Google

the ratio of expansion with alteration in the point of cut-off, and by throttling with a constant ratio of expansion. The engine described in the query, being governed by a throttle valve, has, therefore, the ratio of expansion in the cylinder constant. The steam supplied to the cylinder at each stroke will be of approximately the same volume, but when throttling takes place will be at a lower pressure. Now, there is no advantage in using a high pressure unless a corresponding higher ratio of expansion is employed. With the engine under consideration the ratio of expansion is constant; therefore there will practically be no difference in the efficiency of the engine. Without throttling, steam enters the cylinder at a higher pressure and temperature, but the exhaust will have a proportionately higher pressure. With throttling, although the entering steam is at a lower pressure as the ratio of expansion is constant, there will also be a corresponding lower pressure at the exhaust. The whole question of throttling *versus* expansion is one of great interest to the engineer. Expansion may easily be carried to excess; with throttling there is the very great advantage of re-evaporation on the low-pressure side of throttle valve. This re-evaporation dries the steam. Any heating of the valve and piping would assist in this re-evaporation on low-pressure side. The losses due to radiation and conduction by the pipes would, of course, depend on the insulating material with which they were covered.—M. M.

Answer to No. 700 (*awarded* 5*s.*).—In governing an engine by a throttle valve the loss of pressure in the valve does not represent a corresponding loss of efficiency in the engine. Steam when expanded without doing work has its temperature raised, assuming that heat is neither received from nor given to external surroundings. Thus dry steam passing from the steam-pipe to the steam-chest through the throttle valve is superheated; if the steam be wet, it is to some extent dried. This is due to the fact that the total heat of steam decreases as the pressure decreases, and the pressure in the above case is less on the steam-chest side. The constricted openings of the throttle valve causes the formation of eddies, and the energy expended is converted into heat on the steam-chest side. Allowing for the minute loss of heat through conduction to and through valve walls, etc., the energy is nearly all used again, as it were, in a useful form. For although the pressure is lowered, the temperature of the steam is increased, or the steam is dried, and, consequently, the efficiency of the engine is little, if any, deteriorated. It is a matter of contention, for it is ofttimes stated that throttle governing is as efficient as expansive; in certain cases and at certain loads this is so. A simple relation holds by which the dryness fraction (determining the degree of saturation of the steam) of the steam on each side of the valve: If f_1 and f_2 represent the dryness fractions, L_1 and L_2 the latent heats of steam at the respective pressures, and h_1 and h_2 the heat of the liquid at these pressures, then

$$f_1 L_1 + h_1 = f_2 L_2 + h_2$$

and thus it can be seen that f_2 is greater than f_1.—S. E. T.

Question No. 701.—A few weeks ago I was staying with a friend, when I dropped across something new (to me). He said he had an appointment with a friend, and would I care to accompany him. I consented. It turned out they were experimenting with wireless telephony, one of them worked an ordinary spark coil, giving about an eighth spark. The rest at that end I was not privileged to see, but we got on our cycles and rode to the local club, taking an ordinary receiver of a telephone with us. We connected one wire to the water tap and the other to the gas bracket, and could hear every word that was said at "the other end," about two miles away. Has anyone else seen or heard of anything similar? if so, perhaps the transmitting apparatus would be interesting.

Best Answer to No. 701 (*awarded* 10*s.*).—Personally I have not heard of anything similar, but having experimented with wireless telegraphy, I will give two diagrams, with a possible explanation of them. The first diagram (Fig. 1) is a probable solution to the wireless telephony (so-called) which took place between two parties over a distance of two miles. I doubt if the receiving instrument was so simple as stated, and, as regarding the transmitter, we are not told whether the ⅛in. spark actually sparked when the messages were being sent. T is the telephone with microphonic carbon contacts to enable a strong pulsating current to be used to work the coil; C is the induction coil without the contact breaker being used; C¹ is the induction coil at receiving end; B, the battery; T_1, the receiving telephone. The diagram does not look very wireless; and what would be done if there were no gas or water mains?

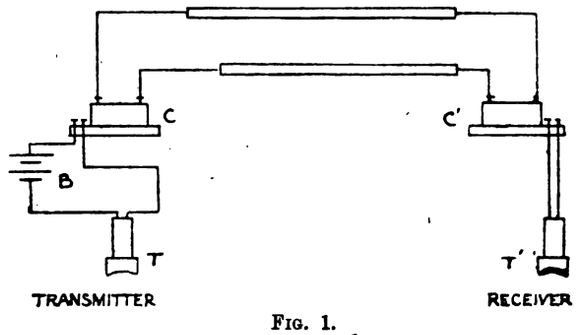

FIG. 1.

Fig. 2 gives the diagram minus the convenient pipes. The secondary wires are taken insulated to two respective points a certain distance apart and earthed. This arrangement works probably owing to some of the stray current from A, in finding its way through the earth back to B, passes through C D. It may also work through a small amount of self-induction between A B and C D. As I have not tried this experiment, I could not say how far this would work with only an ⅛in. sparking coil.

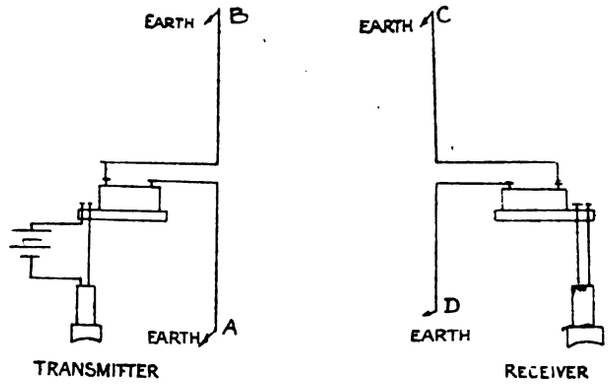

FIG. 2.

In both Figs. 1 and 2 I have not shown a spark-gap, as I doubt if there would be a sufficient variation of current in the primary to produce a susceptible spark in the secondary. According to Kelvin's sparking distance in air, ⅛in. would represent 13,000 volts. A spark-gap would greatly improve matters, owing to the voltage being able to rise till it jumps the gap. Now, this gap might interfere with the articulation of the telephone (1) owing to the higher notes giving a great rate of variation of current, and a consequent long spark in the secondary, whilst the lower notes (2) would give a shorter spark. From the above reasoning, the gap would have to be adjusted to the smallest jumping spark, or the low notes would be lost.

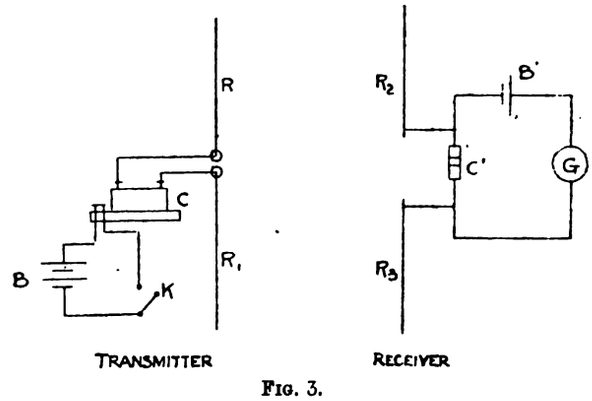

FIG. 3.

Fig. 3 represents a diagram of Marconi's arrangement for wireless telegraphy for a coil only giving ⅛in. spark. Transmitter: C is a coil with contact breaker; B, the battery; K, the key; S and S_1, the sparking balls; R and R_1, the radiators or oscillators (each 2ft. long and supported on insulators). Receiver: R_2 and R_3, the oscillators (same

Digitized by Google

as R and R_1); C, coherer, consisting of brass or iron filings between metal plugs in a glass tube; G, a galvanometer or electric bell, the hammer to be arranged to tap the coherer. In practice it is better to arrange a relay in the receiver, only one cell being used to work the coherer, as only a small E.M.F. is needed. The spark balls can be made to give a more sudden spark by placing them in oil or thick grease. With this arrangement and with the very crudest adjustment one can telegraph 100ft.

Now to refer back to Fig. 1. The oscillations in the pipes no doubt short-circuit through the soil, but owing to the high frequency and voltage the oscillations set up in the pipes can be detected by the telephone. If these vibrations are hardly audible, microphonic contacts on the diaphragm of the telephone, closing a circuit containing another telephone and a battery, would make it more audible. Now, Mr. Marconi does not depend for his telegraphy on currents or oscillations through stray gas-pipes, etc., but purely from the radiation of energy which takes place in the oscillators.—J. ARNOLD.

Answer to No. 701 (*awarded* 5*s.*).—The following may be of interest to "Brackley-Liamena." I take it verbatim from the current number of *Knowledge*: "In a recent issue of *La Energia Eléctrica*, Madrid, May 25, 1904, Mr. G. J. de Guillén Garcia records some interesting experiments made by him in conjunction with his son. In connection with some wireless telegraph researches the son of the author happened to note that in the telephone of the Tommasi coherer located at the receiving station there was a 'sound difference' which varied in accordance with the air-gap in the interrupter of the Ruhmkorff apparatus. This suggested that a similar apparatus would be capable of transmitting the human voice without the agency of a wire. The experiments had to be put off for some time because of the lack of a suitable outfit, but the author was eventually enabled to carry out his idea. The experimental arrangement is a rather simple one. At the transmitting station there is a Ruhmkorff apparatus, 3cm. in spark length, as well as the necessary oscillator, a small antennæ, and an earthed conductor. Between the transformer—*i.e.*, the Ruhmkorff coil—and a small battery of Grenet cells there is a special microphone acting both as manipulator and as interrupter. The automatic interrupter of the induction coil is stopped, while the condenser is used for enforcing the oscillator spark. At the receiving station there is a Tommasi coherer connected to the receiving antennæ and the earthed conductor. In a telephone receiver the noise produced by the Hertzian waves on traversing the coherer is noted. On approaching the mouth of the microphone and singing or speaking, every sound vibration will be attended by an interruption in the passage of the electric current through the primary circuit of the transformer, the number of sparks in the oscillator thus being varied. The underlying principle, therefore, shows some analogy with the mechanism in an ordinary telephone. Any results so far obtained in the reproduction of singing are said to be quite satisfactory, whereas the rendering of language leaves much to be desired. The feeble point seems to be the difficulty of designing a microphone of sufficient intensity. Mr. Garcia, it is true, has remedied the imperfections of his apparatus to a certain extent by using a condenser and augmenting the potential difference. This, however, could not be driven too far, lest electric arcs be formed."—P. Q.

Question No. 702.—On a 500-kw. Parsons turbo-generator the two brushes on both poles nearest armature wear down to a knife edge on a 10-hour run; the others doing 40 hours, have changed brushes, and found all contacts to be good. I should be glad if any of your readers can explain this, also give remedy for the same.

Best Answer to No. 702 (*awarded* 10*s.*).—The most probable cause is that the armature is out of balance. With such high speeds as are usual with this class of machine any slight want of balance becomes a really serious matter. This will be at once apparent from an examination of the formula for centrifugal force, $M v^2/r$. For twice the speed, therefore, the pull due to want of mechanical balance is increased four times. The stress due to this pull has to be borne by that portion of the shaft between the bearings. With a speed of several thousand revolutions per minute an amount of out of balance hardly noticeable with ordinary speeds becomes a source of trouble, if not danger. It would be well to first examine the bearings. These must be a good fit, but not too tight. If the bearings are too loose, there will be vibration; if too tight, they will run hot. Should the armature be out of balance, it may be loaded; this is a troublesome operation, and requires a large amount of skill.

Another cause may be that oil creeps over from the bearing on to face of commutator, causing an increase in the resistance between the outer brushes and the face of the commutator. Thus the greater part of the current passing by the inner brushes, these are worn away more quickly. This might be remedied by having a dished washer between commutator nuts to throw oil clear of the commutator. To give a larger brush contact area, commutators on these high-speed dynamos are sometimes grooved, so that with a given length of commutator there is a maximum of collecting area for the brushes. For mechanical reasons, with these dynamos the sizes of commutator are kept down to as low a figure as possible; therefore this device of grooving makes up, in a degree, for a small commutator.

Generally, each brush should have a connection to main conductor, not depend on frictional contact between holder and brush spindle. Also, to secure good running with these machines, the commutators must be kept in first-class condition; any inequality sets up chattering and intermittent contact at the brushes, by which an undesirable state of affairs is quickly aggravated.—M. M.

Answer to No. 702 (*awarded* 7*s.* 6*d.*).—The probable cause of this trouble is the raising or partial raising of the brushes in question off the commutator by mechanical vibration, and the consequent sparking. The least want of balance in the armature core or winding would, at the high speeds employed, cause an appreciable whip in the spindle. The amount of this whip would be a maximum midway between the dynamo bearings, so that, naturally, the end of the commutator nearest the armature would be most subject to the vibration, and the brushes nearest that end would be more vibrated than the others, and would, therefore, spark more and wear away more quickly. This would more particularly occur with carbon brushes, but even with wire ones might easily account for the difference between 40 hours and 10 hours in the lasting power.

The question of cure is a difficult one, as the reduction of the vibration might involve the rebuilding of the core or the replacing of the present spindle by a stiffer one, and in any case is a matter for the makers to deal with. It may be found possible to work satisfactorily with the brushes nearest the armature removed altogether, perhaps increasing the thickness of the remaining ones somewhat. In any case this should be tried, and, as an alternative, the pressure on the unsatisfactory brushes might be increased.—Q.

Answer to No. 702 (*awarded* 5*s.*).—With regard to this question, I have reason to believe that the cause of the two brushes wearing away so much quicker than the others is due to sparking, caused by them not being kept diametrically opposite. It is usual to feed turbo brushes forward whilst running to allow for the shortening of brush due to the wearing away. It is a good plan to have a gauge to set length of brushes in holder exactly showing length to put through, this being done while running. I had a similar trouble with a 300-kw. machine, and found it to be of great advantage to only strip about $\frac{1}{2}$in. of the gauze cover off the brushes that wore away the quickest, as this kept the brush more solid, and it is less liable to spray, as is the case when stripped the usual distance (1in.). Keep the V in commutator very clean and smooth. This will improve commutation very much.—S. H. LEE.

Answer to No. 702 (*awarded* 5*s.*).—There appear to be only three possible reasons for the rapid wear of these brushes. In the first case, it might be due to variation in the brush material. As, however, the question states that the brushes have been changed, this is evidently not the cause. Secondly, it might be due to excessive sparking, but as no sparking is mentioned, we may also reject this. Thirdly, it may be due to excessive pressure of brushes on commu-

Digitized by Google

tator. If this pressure were due to ordinary causes, we may take it for granted that the questioner would have noticed and removed same. The following explanation seems feasible. If the natural period of vibration of the brushes happens to coincide with that of the turbine, they would tend to press heavily on the commutator at recurrent intervals, and so wear away rapidly. To determine this, increase or decrease the counterweights on the brush-holders, which will have the effect of changing their period of vibration, and so stopping the excessive wear.—H. B.

Question No. 703.—In calculating the cable losses for a certain high-voltage long-distance polyphase transmission scheme with underground cables, an addition was made on account of "dielectric hysteresis." Can this be found in ergs per cubic centimetre as with magnetic hysteresis, and, if so, what are reliable figures for different classes of cable? In the vector diagram, should the current taken by this loss be plotted with the watt-current or the capacity-current?

Best Answer to No. 703 (*awarded* 10*s.*).—It is unusual, when estimating the losses in high-tension transmission mains, to make any allowance on account of dielectric hysteresis, for the loss is, as a rule, so small as to be difficult to ascertain, and is therefore negligible. In an electromagnetic alternating field, energy is consumed in hysteresis due to the molecular friction—that is, instead of the exciting current lagging 90deg. behind the impressed volts, it lags by an angle somewhat less than 90deg. Thus the exciting current consists of an energy component—the hysteresis energy current and a wattless component called the magnetising current. Similarly, energy is also consumed in an alternating electrostatic field. The loss is in the dielectric, and is what is referred to in the question; but, unlike the magnetic hysteresis, the laws and magnitude of the electrostatic hysteresis are but little understood. Experiments tend to show that there are two different components of loss—the one proportional to the frequency, and which, like magnetic hysteresis, is a fixed loss per cycle, independent of the frequency; and one proportional to the square of the frequency, like the eddy currents in iron, and therefore a loss per cycle which varies with the frequency. The loss in watts per cycle in each case can be found per cubic centimetre of volume. The former component is, as stated, independent of the frequency, but is proportional to the 1·6th power of the field strength—it follows the same law as magnetic hysteresis—that is, watts consumed $W = \eta \beta^{1\cdot6}$. Here η is a constant peculiar to the dielectric, and β is the field strength. This is the true hysteresis. The other component varies as the square of the electrostatic field strength, and therefore as the square of the E.M.F. The loss per cycle per cubic centimetre is represented by $W = K N \beta^2$. Here K is another constant, and N is the frequency of supply.

It may be stated at once that for paraffined paper and all dielectrics used in modern practice, the latter component of loss, small even as it is, obscures the former or true hysteresis loss. It should be noted that, taking account only of the latter loss, since it is that lost in the condenser resistance and is constant, and since the capacity or condenser reactance is also a constant for all pressures within the limits of practical work, it follows that the angle of dielectric hysteresis lag is a constant. To find this angle. The capacity current is known, and also the power consumed in the dielectric. The power consumed $= I_c \sin a E$, where a is the angle the value of which is required. In the vector diagram, then, instead of setting off the capacity current 90deg. in advance of the impressed volts, draw it $(90 - a)$ degrees in advance, thus introducing the energy component. Here a different state of things obtain than for the electromagnetic field, for there the permeability of the iron or the magnetic inductance varies, and so the magnetic hysteresis angle of advance is not a constant. From the foregoing it will be seen that while capacity consumes current in quadrature with the E.M.F., which current is, therefore, wattless, dielectric hysteresis consumes current in phase with the E.M.F., and is a power current. Dielectric hysteresis, therefore, appears in the circuit as the energy component of the capacity current.

The writer regrets that he has no reliable values at hand for the constants appearing in the equations given, never having met with any in his everyday work. Concentric cables working under extra high potentials are the only ones likely to be a source of considerable loss, for here the electrostatic gradient is somewhat large; three-core cables, however, are almost invariably the ones employed in power schemes.—T. H. H.

Answer to No. 703 (*awarded* 7*s.* 6*d.*).—It has been observed that high-tension alternating cables become appreciably warm on light loads, much in excess of the rise in temperature corresponding to the $C^2 R$ loss, the extra rise in temperature being due to the loss of energy caused by the insulating material being subjected to rapidly repeated and violent electric strains. This loss by "dielectric hysteresis" closely resembles magnetic hysteresis, but, unlike it, shows no saturation effect, it varying in proportion to some power of the voltage, usually 2 for cable dielectrics. By increasing the thickness of the insulation—*i.e.*, reducing the strain—or by using a dielectric of low specific capacity and working at a low frequency, this loss may be lessened; it also varies greatly in different specimens of the same dielectric, depending on the amount of air and moisture present.

I know of no figures giving the loss in ergs per cubic centimetre of any class of dielectric, but if the capacity per mile and the power factor for any class of cable is known, the hysteresis loss can be approximately determined as follows:

If V = voltage;
n = frequency;
K = capacity per mile in microfarads;
A = capacity current;

then
$$A = \frac{2 \pi n K V}{10^6}.$$

$A \times V$ = apparent watts,

$\therefore A \times V \times$ power factor = true watts.

Then, assuming that the $C^2 R$ loss and the leakage loss are negligible, these true watts will be the loss due to dielectric hysteresis per mile.

A convenient method of determining the power factor of any cable is described by Mr. Mather in the discussion on Mr. Mordey's paper, "Capacity in Alternate-Current Working," read before the Institution of Electrical Engineers. He uses an ironless choker of inductance suitable for bringing the current as nearly as possible in phase with the voltage, and measures the power used in the choker and cable by a wattmeter. The loss in the choker, which is wound with fine wire, is practically equal to C R, the difference between this and the wattmeter reading giving the power lost in the cable.

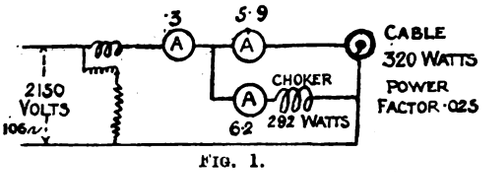

FIG. 1.

Fig. 1 gives a diagram of the arrangement, which speaks for itself.

The apparent watts = 5·9 × 2,150.

True watts taken by cable = 320.

$$\text{Power factor} = \frac{320}{5\cdot9 \times 2{,}150} = \cdot025.$$

In the above test it is essential that the wave-form of the alternator should be a sine curve as near as possible on account of the capacity current varying greatly with the shape of the impressed voltage curve, currents greatly in excess of the theoretical value being obtainable with distorted curves. Below is given a table showing power factor of various classes of cables:

Material.	Voltage.	Frequency.	Power factor.
Oiled paper	2,017	100	·024
Jute	2,030	71·5	·027
Indiarubber	2,000	105	·028

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

QUESTIONS.

711. Give a clear description and example of a method of ascertaining core loss on a direct-current machine by observing the time taken to shut down from its normal speed with field on; secondly, with field off. Given the weights off the moving parts.—E. S. C.

712. Explain the necessity of reactance on the alternate-current side of a rotary converter.—E. S. C.

713. Describe what you consider the best method of truing up large commutators, say from 5ft. diameter upwards.—H. B.

ANSWERS.

Question No. 704.—How would you calculate a blow-out magnet for a controller, given horse-power and voltage. Give the respective advantages and disadvantages of the different designs.

Best Answer to No. 704 (*awarded* 10*s.*).—In the designing of blow-out magnets for controllers a large amount of

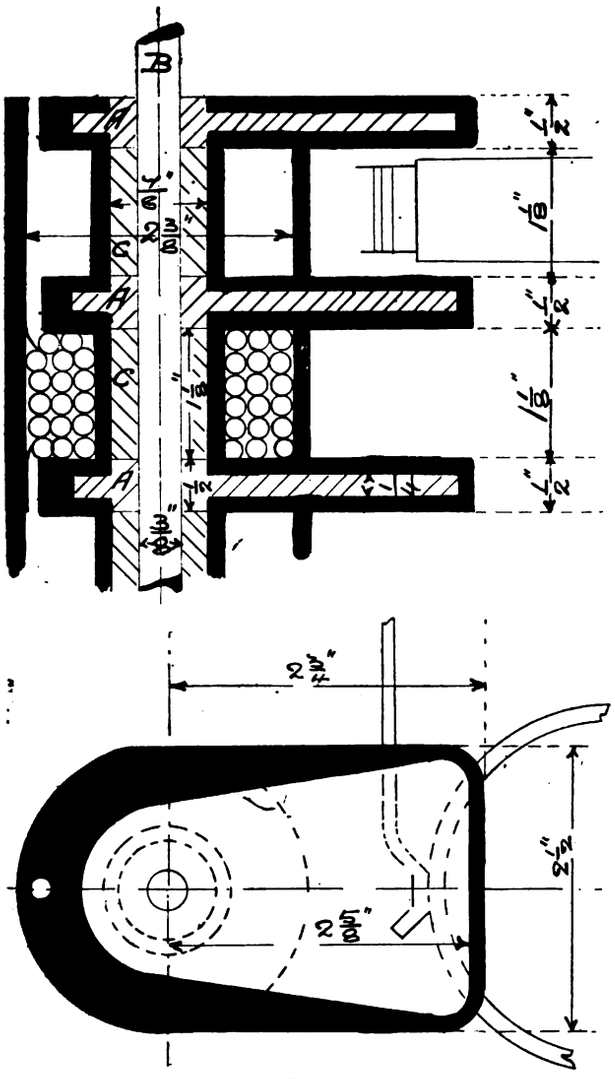

FIG. 1.

experimenting is necessary to first find the most suitable arrangement of the blow-out plates, etc., on which are based the future calculations, the chief point being to get as strong a magnetic field as possible for the circuit to be broken in. The blow-outs used for intermittent working, such as cranes, etc., are so arranged that the amount of watts lost in the coil is higher than if the blow-out was used in a controller made for continuous working. It is generally taken not more than 1½ watts per square inch for intermittent working and ·75 watt per square inch for continuous working.

It has been found that the following arrangement was suitable for use in connection with a 30 e.h.p. 500-volt crane controller, as shown in Fig. 1. The blow-out plates are constructed of wrought-iron drop forgings, marked A, mounted on a wrought-iron centre spindle, B, separated by wrought-iron distance pieces, C. The distance pieces and blow-out plates, also the outside of the winding on the blow-outs, are insulated by means of specially moulded fireproof insulating material, as shown. The distance between each pair of blow-out plates is wound with a suitable size of tape or wire, tape being only used for very large current.

The full-load current of a 30-e.h.p. 500-volt motor being 45 amperes, the winding in this case consisted of four layers of No. 9 S.W.G. S.C.C. wire, each layer having eight turns, making 32 turns for each blow-out. Mean length of each turn equals $1\frac{5}{8}$in. × 3·1416 = 5·105in.; total length of wire per coil = 32 × 5·105 = 13ft.; resistance per yard of No. 9 S.W.G. from Glover's list is ·001476 ohm; resistance of winding on each blow = $\frac{\cdot001476 \times 13}{3}$; watts loss per coil = $C^2 \times R = \frac{\cdot001476 \times 13 \times 45 \times 45}{3} = 12\cdot95$; area of surface equals outside circumference × length = $2\frac{5}{8} \times 3\cdot1416 \times 1\cdot125 = 9\cdot3$ square inches; maximum amount of watts loss allowable per coil = 9·3 × 1·5 = 13·95; and the amount of watts we are losing is 12·95, so that we are on the

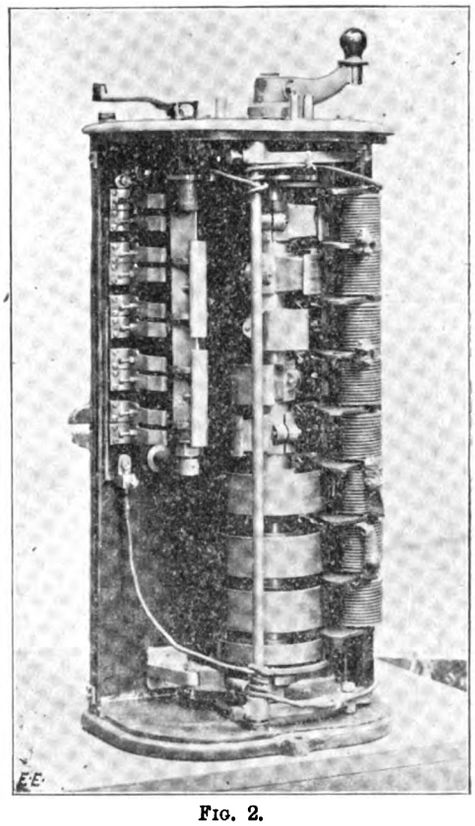

FIG. 2.

safe side. Fig. 2 shows a similar type of blow-out made by Messrs. Royce, Limited, Manchester. The figure in this case shows the blow-out coils before the outer layer of insulation has been put on.

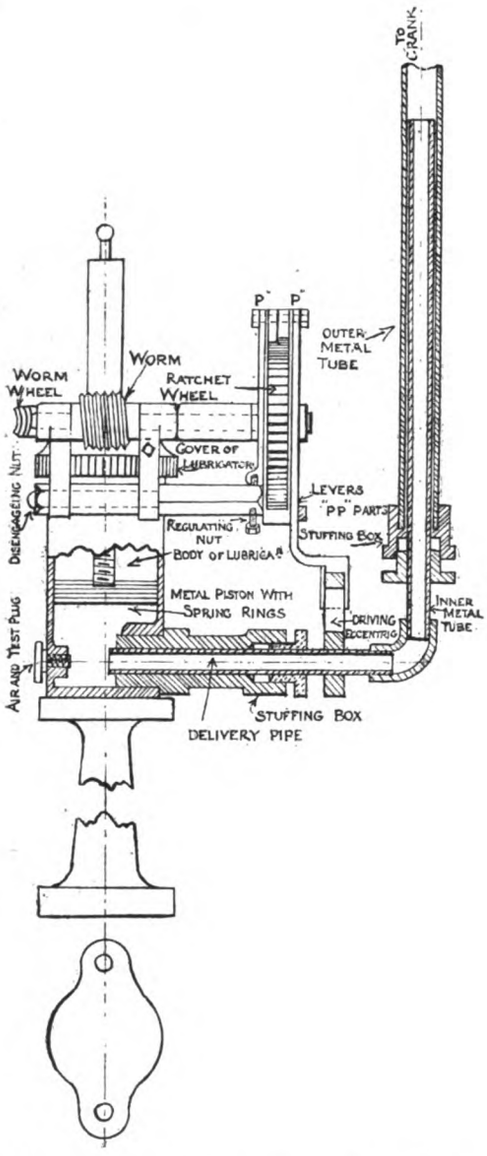
There is only one true blow-out on the market, and that is the type described above. The types consisting of one coil fixed at the bottom of the controller, using the case as part of the magnetic system, are not very efficient.—C. G.

Question No. 705.—What is the most practical method of preventing oil being thrown from the connecting rods and discs of horizontal engines running at 95 revolutions per minute, and having a 3ft. stroke. The engines are fitted with ordinary "Hood" splashguards, but these do not prevent the oil from being thrown out at the sides on to the floor and the frames of engine.

Answer to No. 705 (*awarded* 7*s.* 6*d.*).—Where oil is used for the lubrication of crankpins and cross-head pins and slides, there is only one way of effectually preventing drippings from being thrown, and that is to case in the motion work of engine completely. This practice has been adopted by several of the leading American engine builders,

Digitized by Google

and while, no doubt, being a very efficient method, it possesses obvious disadvantages. Suitable hand and sight holes are provided, and the whole casing (usually made of planished sheet steel) being fitted together in sections can



be taken down to allow of inspection and repair to engine. An excellent method where cleanliness is a desideratum is to use a solid lubricant for crankpins and cross-head motions. The lubricant is delivered under pressure by means of a special lubricator. This system is much favoured by many

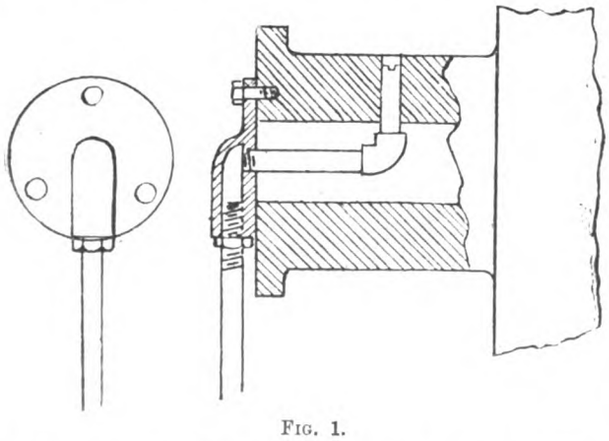


FIG. 1.

engineers in Lancashire and Yorkshire, and is extensively used on large slow-speed engines in the cotton and woollen mills of these counties.

There are many makes of this type of lubricator on the market, one of best being the "Berwal," this particular make possessing the advantage of being of rather simple construction. A sketch of this is given, which may, perhaps, prove self-explanatory. Figs. 1, 2, 3, and 4 show the various methods of drilling crankpins and attaching flanges thereto. A large triple-expansion mill engine lubri-

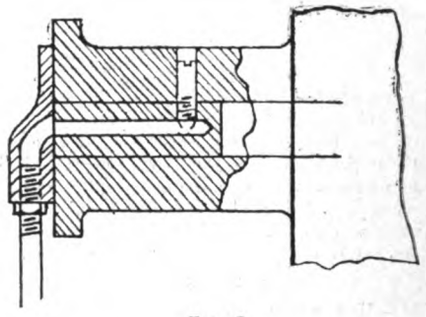

FIG 2.

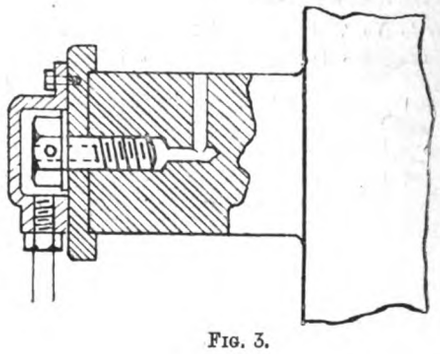

FIG. 3.

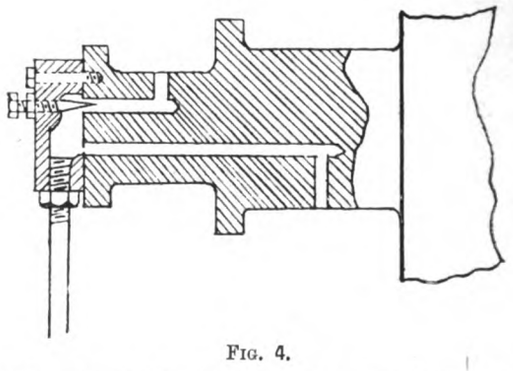

FIG. 4.

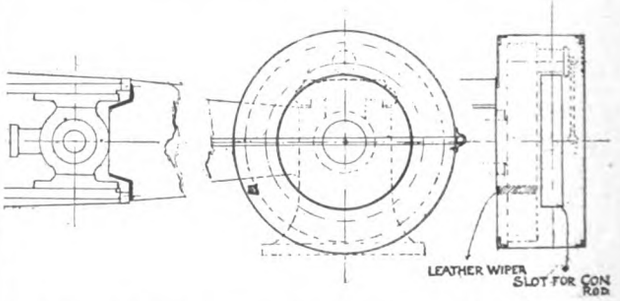
cated throughout with this system of automatic lubrication ran for 2½ years continuously (no stoppage for meal hours), the lubrication giving entire satisfaction.—S. L.

Answer to No. 705 (*awarded* 7*s.* 6*d.*).—The question of oil throwing from the moving parts of horizontal engines is an important one, though often neglected. Ample provision is usually made for conveying oil to the bearings, but often no provision is made to prevent it throwing out anywhere and everywhere.

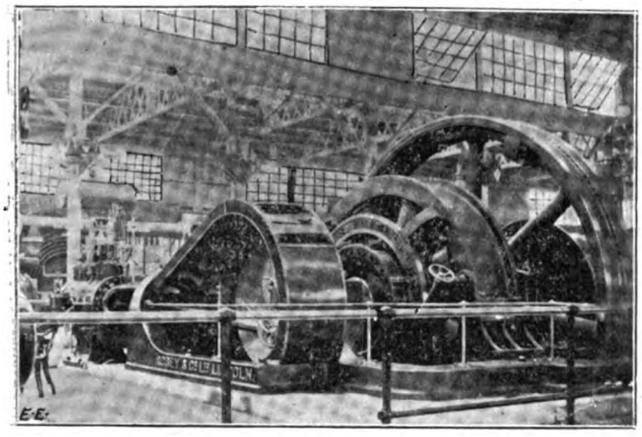
A very simple and effective method of preventing oil splashing from the discs is to have a pad of leather rubbing against the outer edge of the disc, the leather being secured to a piece of flat iron bent to a right angle and screwed to



the bed. For the connecting-rod large end, which is the greatest trouble, a circular blue steel guard built on an angle-iron frame is the most effective. The guard should be as close to the brass as it is possible to get it, and should be as deep as the inner surface of the crank-pin. If provision is made in the design, a cast-iron guard can be fitted

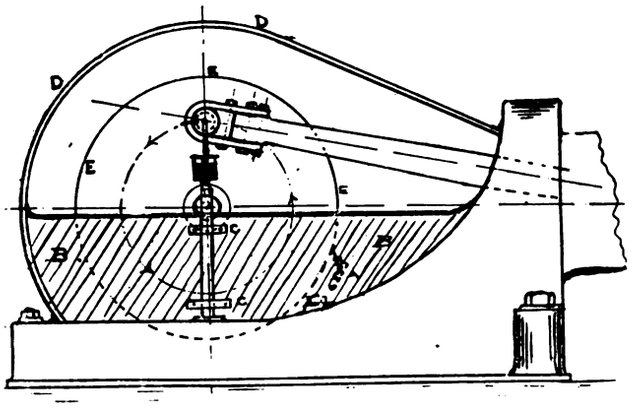
Digitized by Google

much the same shape as the steel one. This type of guard also catches the oil from the main bearings. Oil is sometimes splashed up by the cross-head at the end of the stroke, and a good way to stop this is to fasten a cone-shaped casting or thin steel plate up to the guide end as in sketch. This also allows a well of oil to form and lubricate the guides. Of recent years the Allis type of bed has come into prominence, and as this has the bottom cast in it



is easy to make an effective guard, as shown in the illustration.—A. B. S.

Answer to No. 705 (*awarded* 7*s.* 6*d.*).—The question of preventing the oil which is thrown off from the discs and rods splashing the floor of engine-room and the engine frames is one upon which a considerable amount of thought and ingenuity has been expended, and in some cases the connecting-rod ends themselves have been fitted with oil guards or "catchers" of varying designs and sizes, with,



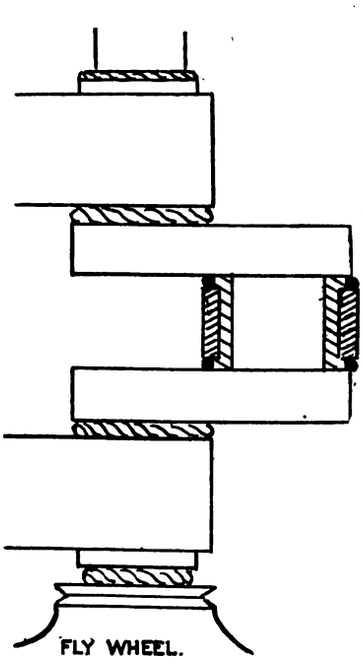
A, Angle Iron Knee, with leather scraper attached; B, Thin Sheet-Steel Screen (shaded), with beaded top; C, Clamps to secure Screen to Oil Standard; D, Hood or Splash Guard; E, Disc.

however, a very small measure of success. The throwing off of the oil from the discs may be almost entirely prevented by fitting oil scrapes, consisting of pieces of leather wide enough to go across the face of the discs fastened on to angle-iron knees, the leather bearing upon the periphery of the disc on the side nearest the cylinder, and the knees bolted to the frame of the engine inside the crankpit (see sketch).

The cause of the splashing seems to be that as the rod-ends describe their circle, the oil which is fed into them, and which works out through the sides, is thrown off at a tangent, some of the drops naturally going upwards, and these, falling again, strike the rapidly-moving rods, and are thrown off again at an angle, and so clear of the hoods, which *can* only stop that oil which is thrown off within their limit. The only practical way of catching this seems to be by fitting a kind of "screen" or "splash plate" right across the crankpit on about a level with the centre of the disc, after style of sketch, and if this be painted in harmony with the rest of the engine and fitted with a neat brass beading, it is an ornament rather than an eyesore, does not prevent free access of air to the moving parts, and is an additional safeguard against accident.—MAFUTA.

Answer to No. 705 (*awarded* 5*s.*).—The best way to deal with the trouble of oil throwing from the big end and crank disc is to fit a sheet steel cover to the open side of the ordinary splashguard. The ordinary guard will deal with all oil thrown off in a longitudinal direction, and the cover, if properly fitted, will prevent any oil being thrown out sideways. The cover should make a tight joint with the existing guard, and should be so fitted as to be easily removed and put up again when it is necessary to make any adjustments to the big end. A good-sized hinged door must be made and fitted in the cover, and should be placed in the path of the crankpin, and where it will be most convenient for feeling the crankpin brasses whilst running, or for nipping up the brasses when the engine is at rest. The post carrying the crankpin lubricator should, of course, be kept outside the casing to allow the lubricator to be filled and adjusted with as little trouble as possible. This method will form a closed crank chamber, and although the big end may run a little warmer, there is no danger of hot ends, provided the connecting rod is properly made and adjusted; whilst the advantages of saving the amount of oil which has previously been wasted, and the keeping of the crankpit free from the dust and dirt which are always attracted to an open crankpit, are well worth having, to say nothing of the saving in labour due to a cleaner engine-room floor and frames. A sketch has not been given, as the arrangement of the ordinary splash-guards on the particular engines will suggest the best shape and extent of the cover.—W. T. W.

Answer to No. 705 (*awarded* 5*s.*).—Although it is practically impossible to completely prevent this trouble, it can, with a little care, be reduced to a minimum. When oil for lubrication is supplied under pressure, stuffing boxes are often provided; these with ordinary attention give good results. Some drivers cut down the supply of oil so that very little is left to be thrown off. This, however, appears to be a dangerous policy. It is better to use oil freely, and after filtering use again on bearings that are not likely to be troublesome. Unless hoods and shields are of an unwieldly size, they do not prevent oil flying off into undesirable places. One of the best, and at the same time one of the simplest, methods is to have a ring of a number of strands of "Berlin" wool round the outside of each bearing. This ring is made up in a similar manner to a "grummet." The accompanying sketch will make matters clear. In the section of connecting-rod strap and brasses, the sections of the wool rings are shown as black dots. Rings are also shown in position round the main bearings. This is a very cheap remedy, is easily applied and renewed, and is not much of an eye-sore. A groove is shown on boss of flywheel; this is a well-known method often used on quick-running machinery. In any case a great deal can be done by wiping down after each run; oil will "creep," and will do much more quickly over a wet than over a dry surface.—M. M.



Question No. 706.—In testing a six-pole, 200-kw., 500-volt machine for a faulty (?) armature coil, the following methods were adopted: The brush leads were connected together, with an ammeter in circuit, and the field was separately excited off the 'bus bars, in series with incandescent lamps, with a current of 6 ampere The machine was run at about half speed (200 to 230 revolutions per minute), and a current of 400 to 600 amperes was maintained. When the machine slowed up with any drop in steam pressure the amperage rose. The lamps in series with the field continually waxed and waned whilst the machine was running, and in switching off these lamps at the end of the run, the last one switched off, thereby breaking the field circuit, became intensely luminous at the instant of switching off. Explain these phenomena.

Digitized by Google

Best Answer to No. 706 (*awarded* 10*s.*). — These phenomena seem very curious at first sight, particularly that the amperage should rise, when the speed decreases, as one of the first rules we learn is that the E M.F. generated in a dynamo armature is directly proportional to the speed when the machine is separately excited. However, in thinking over the problem, we must continually bear in mind that the conditions are not the normal running conditions of the machine; but that, though we are taking more than full-load current from the machine, and, therefore, have a very strong armature reaction and demagnetisation, we have only an exceedingly weak field, the exciting current being probably not more than one-tenth of the normal. The machine is also a "multipolar," there being probably three armature circuits in parallel, and as the machine is only 200 kw., no equalising rings connecting these circuits. Also, the engine is doing very little work, but the rotating armature and the flywheel combined store a good deal of energy, and it is under these conditions that "hunting" or oscillations in the speed of an engine are most easily set up and maintained. Probably other engines are running off the same steam-mains, and these will set up periodic oscillations in the steam pressure, which oscillations will, therefore, be transmitted to the engine under consideration; and even if this were not the case, we can easily conceive the engine speed to be periodically varying from a maximum to a minimum and *vice versâ*, the period of these oscillations being a few seconds probably.

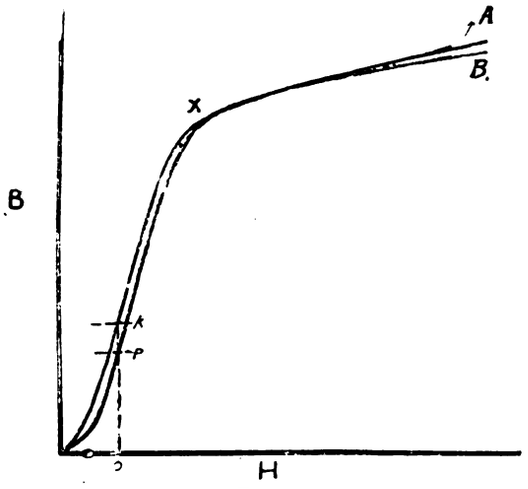


Fig. 1.

Now, let us consider the electrical side of the case. The field magnets of a dynamo are never all of exactly the same quality of iron, and probably if we had a B H curve for two of the field magnets we should find them something like A and B in Fig. 1. If, then, the magnets are excited fully, as, say, at the point X, the percentage difference in the inductions of the two fields is small; but if they are only partially excited, the induction in A may be O P and in B it is O K, the difference in induction P K being quite a large percentage of the total. We see, therefore, that with fields weakly excited the poles vary in strength much more than if the fields are all "stiff" The three armature circuits which are in parallel will then have varying E.M.F.'s developed in them, and we shall, therefore, have cross-currents round the armature, which do not pass through the ammeter, but simply round the brush connecting rings, and these will have a considerable action on the weakly magnetised poles of the generator, alternately demagnetising and magnetising, and thus causing the flux in them to alter, and causing first back, then forward, E.M.F.'s in the field coils themselves, therefore variations in current in the field coils, and waxing and waning of the lamps in series with them. These cross-currents in the armature coils have been noticed particularly in large tramway generators when sudden changes of load occur, the currents being found to grow to a maximum, then die away again, grow again, and so surge from a maximum to a minimum, giving rise to sparking at the brushes every few seconds, the action being known as "bucking."

It is probable that when the machine is running at half speed these electrical surgings are of the same periodic time, or some multiple of the mechanical oscillations of speed, and they therefore assist each other, and we have large cross-currents; whilst when the speed falls, due to falling in steam pressure, the oscillations are no longer of the same period, and therefore check one another, and we have less cross-currents. There will then be less C^2 R loss in the armature and potential drop due to these currents, and, therefore, though the speed be a little less, the current in the ammeter circuit will rise. The reason the lamp grew intensely luminous at switching off is

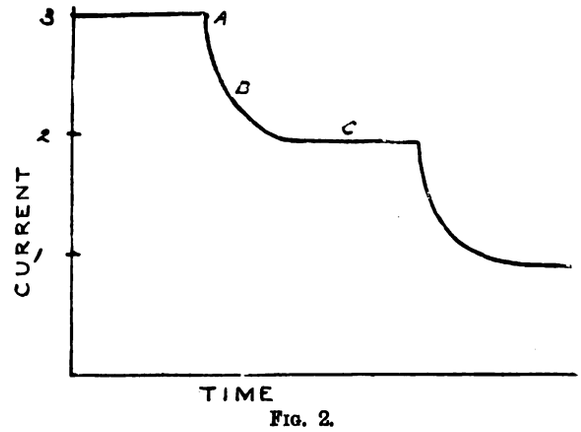

Fig. 2.

because the current has a large inductance, or magnetic inertia, which resists sudden changes of current, and, therefore, tends to keep the current through the lamp and field constant when switching off. If we had only one lamp in series with the field, then on switching off we should have a large spark at the break, but the lamp would not glow more brightly, since it cannot do this without an increase of current, and the inertia of the magnetism tends to prevent an increase of current just as it tends to prevent a decrease. The reason is that we have, probably, three lamps in parallel, and then are switched off one after another quickly, not allowing the current time to decrease. Fig. 2 shows how the current would fall off as the lamps are switched off. At A one of the lamps is switched off, and the current then falls to the value at C, corresponding to the steady current for two lamps, but it does not do this instantly, but at a point, say B, we have a larger current through the two lamps than the normal current at C, and, therefore, the lamps are glowing more brightly than the normal. The same happens in a greater degree when the last lamp but one is switched off, then nearly twice the previous current passes through the last lamp for an instant.

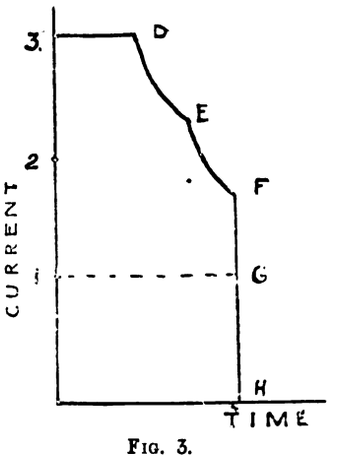

Fig. 3.

Fig. 3 shows how the same results are intensified if the switches are pulled out more quickly, one after another. At D we switch off one lamp, and before the current has reached a steady state we switch off another at E: then, on switching off the last lamp at F, the current through it is H F, whilst the normal current for the lamp is H G.—W. S. P.

Supplement to "The Electrical Engineer,"

AUGUST 5, 1904.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

714. Give, with sketch, what you consider the best method for testing car axles; also the remedy for crystallisation, which has been found to take place just at the boss of wheel. All axles have been found broken at the same point, just inside the hub.—HIERONS.

715. Explain the principle underlying and give sketch showing the connections of starters for single and two phase alternate-current motors from 4 h.p. to 30 h.p. I do not refer to liquid starters, but to those made by the E.C.C., which have a two-way marked "start" and "load," and appear to be some sort of transformer device.—DIRECT CURRENT.

716. In inspecting Lancashire boilers, what are the chief places to watch for defects?—H. B.

ANSWERS.

Question No. 706.—In testing a six-pole, 200-kw., 500-volt machine for a faulty (?) armature coil, the following methods were adopted: The brush leads were connected together, with an ammeter in circuit, and the field was separately excited off the 'bus bars, in series with incandescent lamps, with a current of ·6 ampere The machine was run at about half speed (200 to 230 revolutions per minute), and a current of 400 to 600 amperes was maintained. When the machine slowed up with any drop in steam pressure the amperage rose. The lamps in series with the field continually waxed and waned whilst the machine was running, and in switching off these lamps at the end of the run, the last one switched off, thereby breaking the field circuit, became intensely luminous at the instant of switching off. Explain these phenomena.

Answer to No. 706 (*awarded 7s. 6d.*).—To answer this question we will assume that the fault consists of one or

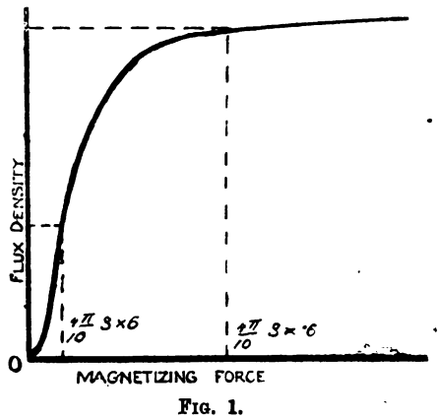

FIG. 1.

more short-circuited coils, and we will see how this would account for the effects noted. The current taken by the shunt winding of a machine of this size would be about six amperes, this corresponding to 1½ per cent. of the full-load output, and as it is stated that by means of lamps connected in series with the shunt winding the current is reduced to ·6 ampere, the field magnetism will be very weak, a small change in the magnetising force therefore causing a considerable change in the flux density (see Fig. 1). As the short-circuited coil revolves, passing poles of opposite polarity, an alternating E.M.F. will be induced in it, causing a current to circulate, which, if the coil is "dead shorted," will lag by nearly 90deg. This will be seen to be the case, since $\tan \alpha = \frac{p L}{R}$.

where α = angle of lag;

$p = 2\pi$ times the frequency;

L = coefficient of self-induction of the coil;

R = resistance of coil and fault, which in the above case is very small.

Consider the coil in the position shown (Fig. 2). The E.M.F. induced in it will be at its maximum, but the current, owing to it lagging, will have just passed through its zero value, and will be flowing in such a direction round the coil as to demagnetise the magnet pole which it is

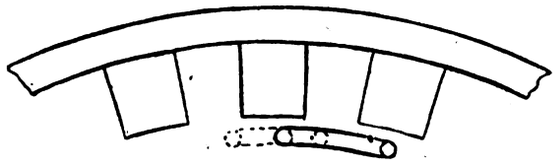

FIG. 2.

approaching. As the coil moves forward the current in it increases, and will pass through its maximum when the centres of the coil and pole nearly coincide (depending on the angle of lag), in which position it has the greatest demagnetising effect. During this movement of the coil the flux through the magnet core will be increasing, inducing an E.M.F. in the field coil which tends to oppose this change. This E.M.F. will, therefore, act in the same direction as the 'bus-bar voltage, thus causing more current to flow through the coils and lamps. Consequently the lamps increase in brightness. Again, as the coil moves from this latter position (shown dotted in diagram) its demagnetising action on the magnet core will decrease, thus allowing the magnetism in the pole to attain its original value, which change in flux will induce an E.M.F. in the field coils opposing the 'bus-bar voltage. The current through the field coils and lamps will, therefore, be decreased, causing the lamps to become dim. As this effect occurs every times the coil passes a pole, the lamps will wax and wane, as stated in the question.

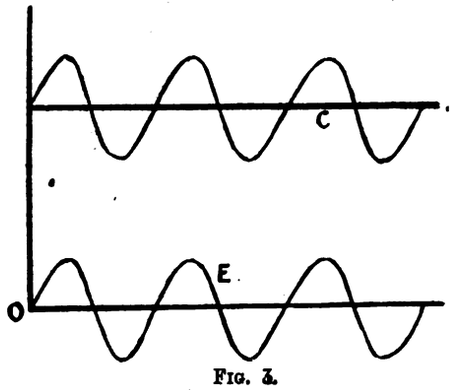

FIG. 3.

It is seen from the above that the current through the field coils, and consequently the magnetism in the poles, is pulsating between certain maximum and minimum values, causing two E.M.F.'s to be induced in the armature conductors—viz., a pulsating one in phase with the field, due to the armature's rotation; and an alternating one at right angles to the field, due to the armature acting as a secondary

Digitized by Google

of a transformer. This latter E.M.F. we may neglect, since the current it produces is small, depending on the lead of the brushes, and would be nothing if the brushes were in their neutral position.

The pulsating E.M.F. due to rotation may be resolved into two components, a steady E M.F. (C) and an alternating E M.F. (E), as shown in sketch (Fig. 3) This alternating E.M.F. generates a current which will lag considerably (as explained above), consequently demagnetising the fields. When the speed of the machine falls, the current through the short-circuited coil will remain practically unaltered, but the rate of demagnetising the fields will be decreased. The E.M.F. induced in the field coils will therefore be less, causing the current, and therefore the magnetism, to pulsate between smaller values. The combined effect of this and the speed falling is that the alternating component of the above E M.F., and consequently the current, is reduced, also the angle of lag, thus reducing the demagnetising action on the fields. Should the voltage induced by the increased strength of fields be greater than that corresponding to the drop in speed, the current through the armature will increase, which seems to be the case for the machine in question. The increase in brightness of the last lamp on breaking the shunt field is caused by the collapsing field inducing a large E.M.F. in the field coils, and sending a current through the lamp, and a non-inductive resistance, which is evidently connected in circuit across the field coils at the moment of disconnecting them from the 'bus bars.—C. L. S.

Answer to No. 706 (*awarded* 5*s.*).—The following will perhaps be one explanation of the phenomena described by "A." in Question 706. The engine being run at approximately half speed, the governors would not regulate the steam supply so satisfactorily as under the normal speed for which they were set, consequently the speed of the engine will vary. If the speed rises, a greater E.M.F. will be maintained at the brush terminals of armature, and as the brushes are simply connected through an ammeter (the resistance, leaving out heating effect, unaltering), a greater current will flow and the engine will slow down. The current, as stated in the question, rises from 400 to 600 amperes. The dynamo being but a 200-kw. machine, allows a normal capacity of 400 amperes, hence it is seen that at times the current is too much in excess, and consequently brings about armature reactions, which tend to distort and weaken the field magnets. This fluctuation in the field causes a variation in the lines of force, which are produced by the exciting current This variation is felt directly by the coils surrounding the magnet cores, and as the lamps are in series with the field coils, they also vary accordingly. When the field magnets become weaker owing to armature reaction, the armature generates less E.M.F. for a given speed, consequently the current is again diminished, and less is the torque demanded of the engine; hence the engine again rises in speed, and the above cycle is once more gone through. The rises in amperes cannot be due to the slowing of the engine, as stated by "A." for this would be producing greater torque corresponding to a fall of steam pressure, which is not so. The most probable reason is that the greater current generated demands a greater supply of steam, hence the pressure falls.

Concerning the switching out of the lamps. ("A." does not say whether they are in parallel or in series with one another before being connected in series with the field.) In any case when the exciting circuit is broken, either through the switching out of one lamp when in series or the last when in parallel, an induced current is set up, caused by the collapsing of the field lines across the coils. This induced current flows in the same direction as the original current, and the increased voltage causes the increased luminosity of the said lamp. In switching out field coils, it is usual to have specially provided switching gear, which cannot be entered into here. A little more detail concerning the armature, number of brushes, winding, etc., might have been helpful.—WILLIAM BEARD.

Question No. 707.—Describe the process of determining the permeability of a specimen of iron in the shape of an anchor ring for a given magnetising force.

Best Answer to No. 707 (*awarded* 10*s.*).—I have recently carried out a large number of permeability tests by the ring method, and I will therefore describe exactly the apparatus I used, and the method of carrying out the test. Where a number of samples are to be tested, it is advisable to have the rings of uniform size in every particular, and this can be obtained with certainty if the rings are of rectangular cross-section. In order to reduce the calculations to a minimum, every ring was wound alike, and the number of turns on the primary calculated so as to give the value of H as a simple multiple of the value of the current in amperes. The ballistic galvanometer was calibrated so that the value of the swing, θ, multiplied by a constant, K_g,

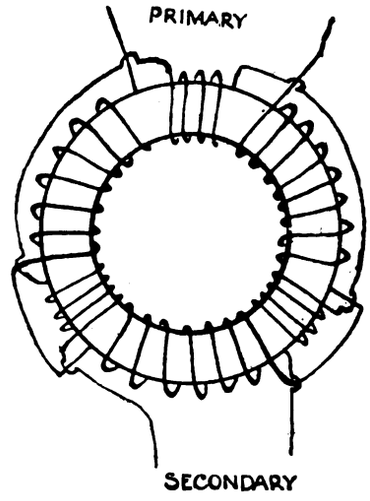

FIG. 1.

was equal to the change of B in the iron ring. The rings were first carefully measured by means of vernier gauges. They were then wrapped with a layer of thin tape. (The tape should not be wider than $\frac{1}{4}$in., or it cannot be laid tightly on the iron.) They were then wound with a primary and secondary winding, as in Fig. 1. The primary was divided in three sections, and the secondary into three sections, and wound so that they did not overlap, as shown in the figure, and then the respective sections connected in series The wire on the primary was 16 S W.G. copper, double cotton covered, and on the secondary 36 S.W.G. copper, double cotton covered. By thus dividing the windings, the secondary coil can be wound directly next to the iron, and at the same time wound *after* the primary, thus eliminating the danger of damage to the secondary by winding the primary on top of it. Moreover, the labour of winding is considerably lessened. The number of turns, etc, will be considered later.

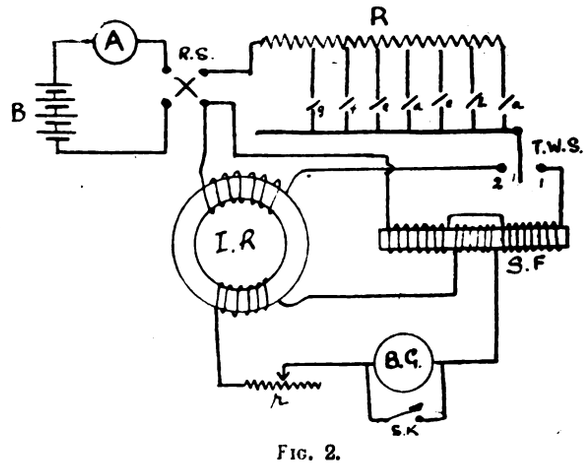

FIG. 2.

The apparatus employed is illustrated diagrammatically in Fig. 2, and is as follows: I R, iron ring under test; B G, ballistic mirror galvanometer of the moving-coil type; r, box of resistance coils in the galvanometer circuit; S F, standard solenoid for calibrating B G (a Hibbert's standard magnetic field may be used instead of S F if desired); R, rheostat in the primary circuit, and is made so that the

Digitized by Google

current may be altered *quickly* and *definitely*; B, four or five secondary batteries, capable of maintaining a steady current of about 30 amperes; R S, reversing switch; A, ammeter of the moving-coil type, scale divided into not less than 150 divisions; T W S, two-way switch; S K, spring key for short-circuiting the coil of the galvanometer to bring it quickly to rest.

In order to be certain that the windings on the rings have not been short-circuited or damaged by the edges of the iron, it is a good plan to determine either by trial or calculation the length of wire necessary for each section, and then determine its resistance, first before it is wound and then after winding. It is also necessary to be certain that the sections of the primary form a continuous solenoid and also those of the secondary.

Method of Testing.—The apparatus was connected up as in Fig. 2, with all switches open, and T W S arranged on contact 2. The resistance, r, was increased until the damping effect on the galvanometer coil was of a negligible amount—that is to say, so that the galvanometer was acting truly as a ballistic one. Then trials were made. The spot of light was brought to rest at 0 on the scale, by means of S K. Then switch a was closed, and the deflection of spot noted. The spot was again brought to rest, and switch b closed, and so on, increasing r if necessary, so that in no case the spot of light was deflected off the scale. All switches were now opened and the ring demagnetised. This was done by connecting the primary winding to a motor-driven alternator, whose field was excited so that the armature gave about eight or ten volts. The machine was run up to speed and then the motor switched off, thus allowing the machine to come slowly to rest. Another method of demagnetising is to use the reversing switch, R S, and then, commencing with a current sufficient to overcome the residual magnetism, to gradually diminish the current through the circuit to a very small value, say 0·01 ampere. The ring was then replaced as in the sketch, T W S was put on contact 1, and current switched on to the primary of the standard solenoid, the magnitude of the first swing of the spot of light and the current in amperes being noted.

This procedure was repeated with several values of the current and a mean of the results obtained (see table). N.B.—The spot of light was brought to rest after each swing. All switches were now opened and T W S moved to contact 2. (Care is now necessary, as an error in one reading will necessitate demagnetising the ring and commencing again.) Switch a was then closed and θ and A noted. Switches b, c, d, etc, are then successively closed, each time noting θ and the corresponding current, and the observations tabulated as below. After reaching the maximum current the switches were opened, and a check test made by demagnetising the ring and repeating the test with the current reversed, so as to magnetise the ring in the reverse direction.

Calculations, etc: Particulars of Standard Solenoid.—Number of turns on primary, 464; ditto secondary, 100; length of primary, 150 cm.; mean area of secondary, 186·5 square centimetres. Secondary wound under primary and about the middle, on a wood cylinder.

Particulars of Iron Ring and Winding.—Material, cast iron; external diameter, 5in. = 12·7 cm.; mean diameter, $4\frac{5}{8}$in. = 11·62 cm; mean circumference = length of magnetic path = 36·9 cm.; width of iron = $\frac{3}{4}$in. = area of cross-section = $\frac{9}{32}$ square inch = 1·81 square centimetres; number of turns primary, 147; ditto secondary, 100. Since the core of the standard solenoid is practically air, and therefore of unit permeability, the relation between N, the total flux embraced by the secondary, and A, the current in amperes flowing through the primary, can be determined and expressed as K . A.

$$\text{where } K = \frac{\cdot 4\pi \times \text{turns primary} \times \text{area . secondary}}{\text{length . primary}}$$

$$\therefore K = \frac{\cdot 4\pi \times 464 \times 186\cdot 5}{150}$$

$$\therefore N = 725 \times \text{amperes.}$$

Now, also, for each ring $\frac{\cdot 4\pi \times \text{primary turns}}{\text{length of path}}$ is a constant, and therefor H for the ring may be expressed as $K_1 A$, and by calculation the number of turns required to make $K_1 = 5$ were determined; hence H for ring = 5 × amperes.

In calibrating the galvanometer, θ (the magnitude of the first deflection), is proportional to the number of lines cut by the secondary coils. Hence $\frac{K A}{\theta}$ = the number of lines cut to produce one division deflection, and since the number of turns (secondary) on the solenoid and ring is the same, they do not come in the calculation. If now $\frac{K A}{\theta}$ be divided by a, the area of cross-section of the iron, then $\frac{K A}{\theta a}$ = change of B in the iron represented by one division deflection. If, however, the number of secondary turns on the ring be not the same as that on the solenoid, then change of B in the iron represented by one division

$$= \frac{K A}{\theta a} \times \frac{\text{number of turns on standard}}{\text{number of turns on ring}}$$

This may be called K_g, and is the constant of the galvanometer; and thus when measurements are taken on the ring, $K_g \times \theta$ = the change of B in the ring.

From the accompanying tables of observations a B-H curve can be plotted, and the permeability of the iron for any value of H interpolated.

Calibration of Galvanometer.

Amperes.	θ	K_g.
1·06	45	9·43
2·12	91	9·33
1·5	64	9·4

Mean K_g = 9·39.

Observations on Ring.

Amperes.	H	θ	Total θ	B	μ
0·68	3·4	30·5	30·5	280	82·4
1·34	6·7	61	91·5	841	125·5
2·0	10·0	111	202	1.857	185·7
2·6	13·0	106	308	2,835	218
3·26	16·3	92	400	3,680	226
3·7	18·5	51	451	4,150	224
4·16	20·8	47	498	4,580	220
8·14	40·7	250	748	6.880	169
11·6	58·0	110	858	7.900	136
14·56	74·8	70	928	8.530	114
18·1	90·5	50	978	9.000	99·5
20·74	103·7	36	1,014	9,330	90

In order to convert the values of H and B to inch measure, it is only necessary to multiply them by $2\cdot54^2$. Obviously, then, if a number of rings are to be tested, and they are of uniform size, etc., it is only necessary to work out the constants for one ring, and the calculations for the whole of the rings become of the most elementary character.

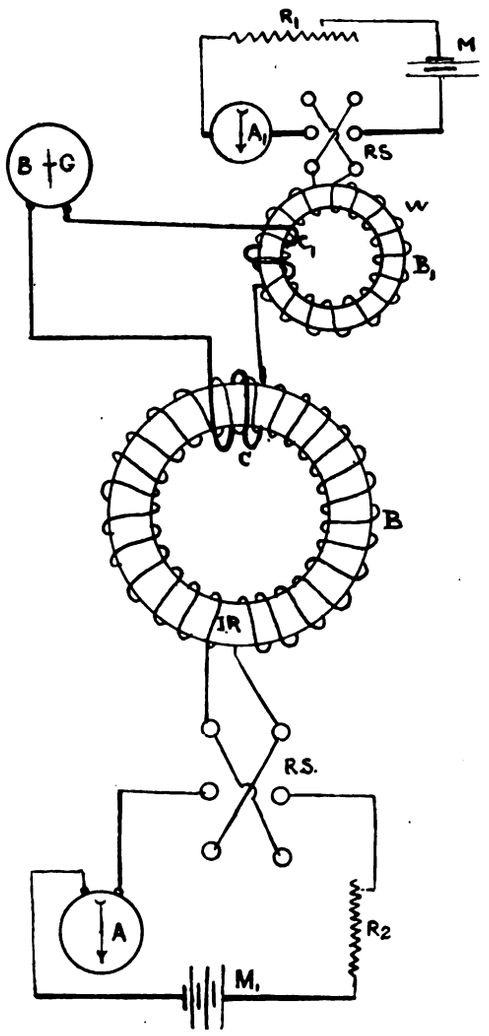
Thus $H = K_1 A = 5$ A in this case.
$B = K_g \theta = 9\cdot39\ \theta$ „ „ —M. S. T.

Answer to No. 707 (awarded 7s. 6d).—General.—It is a well-known fact that a magnetic field exists in the neighbourhood of a conductor carrying an electric current. The direction in which this field acts can be readily determined. It is also a matter of common knowledge that some substances offer greater facilities than others for the propagation of these lines of force. The relative power for conducting these lines is termed the permeability. In order to be able to definitely compare this property in various substances, some standard must be adopted; for this purpose the permeability of a vacuum is taken as unity, but that of air is almost exactly the same, and is a more convenient standard. Hence the permeability of any substance might be estimated by dividing the number of lines of force which pass through by the number which pass through the same space when the substance is removed, the magnetising force being the same in both cases. There is, unfortunately, no method available for determining the actual number of lines of force pervading any particular space or substance. The nearest approach we can get to this is to measure the strengths of the resulting electromagnetic fields, which, as might be supposed, are proportional to the number of lines. These field strengths are easily compared by comparing the magnitude of the various phenomena which can be made to take place in them. Fig. 1 shows a simple arrangement of apparatus for

Digitized by Google

performing these operations with an anchor or continuous iron ring.

Description of Apparatus.—The magnetising coil, B, is wound uniformly over the whole ring, I R, and is connected in series with a battery, M_1, an adjustable resistance, R_2, for varying the currents strength, an ammeter, A_1, for measuring the current, and a reversing switch, R S. The other circuit consists of a small coil, c, in series with the test coil, c_1, of a wooden cored coil (for calibration), and a ballistic galvanometer, B G. This small coil, c, should, if possible, be wound next the ring, so as only to embrace lines actually passing through the iron. A ballistic galvanometer consists essentially of a galvanometer having a somewhat massive needle. The reason for using a galvanometer of this type is that, the inertia of the moving parts being



I R, Ring under test; B G, Ballistic Galvanometer; A A, Ammeters; M M, Batteries; R S, Reversing Switches; R1 R2, Adjustable Resistances; C C1, Test Coils; B B, Magnetising Coils.

great, the whole of the transient current will have passed through the galvanometer before it has moved appreciably from its mid position. Thus the needle receives the whole of the impulse while in the most sensitive position, and therefore the deflection will be proportional to the total quantity of electricity passed independent of any variation in the time element.

Explanation: Definitions.—The number of lines passing through a square centimetre is called the magnetic induction, and is denoted by the symbol B. The intensity of the magnetising force, denoted by H, is in air equal to magnetic induction B, as the permeability of air is unity. The permeability of a substance, usually denoted by μ, $= \frac{B}{H}$.

To Find the Intensity of the Magnetising Force (H).—The magneto-motive force for any magnetic circuit is proportional to the product of the number of convolutions, N, in the solenoid and the currents strength, c—that is, the M.M.F. $= k$ N C and the intensity of the magnetising force $= k\ n\ c$, where n = number of convolutions per unit length. The factor k actually equals $\frac{4\pi}{10}$, the 4π being due to the definition of unit current and the 1/10 to the fact that the C.G.S. unit of current = 10 amperes, therefore $H = \frac{4\pi nc}{10}$.

To Measure the Magnetic Induction (B).—To compare the strengths of different fields, use is made of the fact that when a conductor cuts lines of force an E M.F. is induced in it, and if it forms part of a complete electrical circuit, a current will flow. For instance, supposed we placed in a certain magnetic field a small coil just one square centimetre in area and at right angles to the lines of force, this coil will embrace a number of lines equal to B If we suddenly remove the coil from this field, the resulting current will be proportional to this number. By placing the same coil in another field and removing it just as quickly, a second current will be obtained proportional to the second field. Of course, the resistance of the circuit and the other conditions must be maintained the same in both cases. Hence, knowing the strength of one field, we can calculate the value of the other. But instead of using a coil one square centimetre, we may use a larger one and obtain B by dividing the total flux by the effective area of the coil; also instead of removing the coil from the field, we may turn it through a right angle: it will then be parallel to the lines of force and enclose none, or we may turn it through 180deg. and cut the lines twice. Or, better still, instead of moving the coil, we may take away the lines in force or reverse them; the latter is the method adopted of this experiment.

Calibration of Galvanometer.—The calibration is accomplished by means of the wooden cored coil shown as w. The coil merely consists of two windings, one connected through an ammeter, A, and variable resistance, R, to a battery, M (magnetising coil), and the other a test coil connected to the galvanometer, both wound on a wooden core. The object of using a wooden (non-magnetic) core is that its permeability being unity the magnetic induction equals the magnetising force, and as we have seen that the intensity of the magnetising force $= \frac{4\pi nc}{10}$, hence, if we observe the number of convolutions per unit length of magnetic path, n, and the current, C, we can calculate the induction, B. By varying the resistance, R_1, we shall obtain different values of c, and hence of B; and by observing the throw of the galvanometer occasioned by throwing over the reversing switch, R S, in each case, it will be possible to obtain a curve co-ordinating B with galvanometer deflection. With a Kelvin galvanometer (the time of oscillation being made great, by causing the needle to move in a very weak field, by opposing the permanent magnets to the earth's field), calibrated by the writer for this purpose, the curve obtained was practically a straight line.

Instructions.—We are now ready to proceed to the actual test of the ring. Adjust R_2 to give the current required for the given magnetising force. Note the value of the current as given by ammeter, A, throw over the reversing switch and note the throw of the galvanometer. It should be noted here, as well as above, that the lines of force have been made to vanish and to reappear in the opposite direction, hence the throw will be proportional to 2 B. Then calculating H from the formula $H = \frac{4\pi nc}{10}$, and observing B from the calibration curve found above, we can easily find μ from the equation $\mu = \frac{B}{H}$. This should be repeated two or three times, and if any variation occurs, a mean should be taken.—H. E. H.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

ANSWERS.

Question No. 707.—Describe the process of determining the permeability of a specimen of iron in the shape of an anchor ring for a given magnetising force.

Answer to No. 707 (*awarded* 7*s.* 6*d.*).—The permeability of a substance is the ratio of the magnetic induction in the substance to the magnetising force, or $\mu = \frac{B}{H}$. Now the value of H produced in a given coil can be calculated when we know the current flowing in the coil and the number of turns per unit length of the coil. We have, therefore, to determine experimentally the value of B for various applied values of H, or obtain a B-H curve for the iron, and we can then readily calculate the permeability.

The first thing to be done, then, is to carefully measure the size of the anchor ring with a pair of callipers, measuring (in Fig 1) the dimensions *d*, D, and *w* in centimetres. Then the mean length of the magnetic circuit is

$$\pi\left(\frac{D+w}{2}\right) \text{ centimetres,}$$

and the cross-sectional area is equal to

$$\frac{\pi \cdot d^2}{4} \text{ square centimetres.}$$

We have now to wind a magnetising coil round the ring. Probably a double layer of No. 20 S.W.G. will be sufficient,

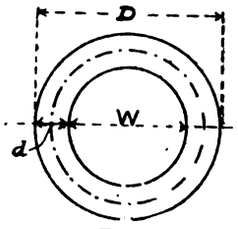

FIG 1.

and this should be wound evenly round the whole ring, and the total number of turns counted. Let it be *n* turns. Then the number of turns per centimetre will be

$$\frac{n}{\text{mean length of path}} = \frac{n}{\pi\left(\frac{D+w}{2}\right)}.$$

Call this S. Then, if we pass a current of C amperes through the coil, the magnetising force in the ring is

$$\frac{4\pi}{10} S C = H.$$

We now require to be able to measure the values of B produced when various values of H are applied. To do this, we require a ballistic galvanometer—that is, a galvanometer whose suspension has a large moment of inertia, but very small damping action. This galvanometer has to be standardised, either by rotating a large coil of many turns through 180deg., cutting the earth's horizontal field, the galvanometer being in series with the coil, the rotation being performed very quickly, and the maximum deflection of the galvanometer noted. Or a better, and more usual, method is to use a standard solenoid having an exploring coil at its centre in series with the galvanometer, and to note the deflection produced on the galvanometer, when a current of one ampere is suddenly reversed in direction through the solenoid. In order to avoid having to apply connections for the ends of the solenoid, it should be at least 12 diameters long. (The error introduced by the ends will then be only about 1 part in 300, and may, therefore, usually be neglected.)

A good form is to wind a uniform layer of about No. 20 S.W.G. copper on a split brass tube, say, 2½in. diameter. The exploring coil is then wound of fine wire—say No. 36 silk-covered copper—on a light split brass bobbin which will just slide in the brass tube of the solenoid. We may have about 200 turns on this bobbin, and the leads leading away from it should be twisted together. Fig. 2 shows part of a section through the centre of the solenoid, showing the bobbin and fine-wire coil in the centre. The number of turns on this bobbin should be noted, and also the mean diameter, *a*, of the turns. Then we know that the flux

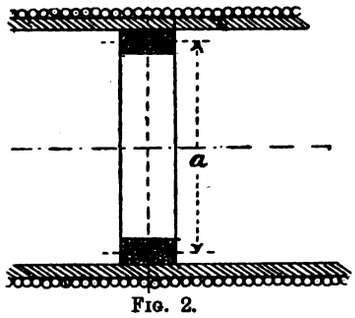

FIG. 2.

passing through the exploring coil for current, C, in solenoid is equal to

$$\frac{4\pi}{10} S C \times \frac{\pi a^2}{4} = H \times \text{area.}$$

Therefore, if current is suddenly reversed in direction, the flux cut will be

$$2 \times \frac{4\pi}{10} S C \times \frac{\pi a^2}{4}.$$

Thus, knowing S and *a*, we may standardise our galvanometer by having it in series with our exploring coil, and noting the deflection when a current, C, is reversed in the solenoid.

We now need an exploring coil on our ring specimen. The number of turns necessary will depend on the size of the ring and the sensitivity of our galvanometer; perhaps 10 turns will suffice. The connections have now to be made as in Fig. 3. The galvanometer should be connected up in series with the two exploring coils, and a resistance if necessary, and this circuit should not be altered at all during the experiment, as we wish to keep the "damping" of the galvanometer constant.

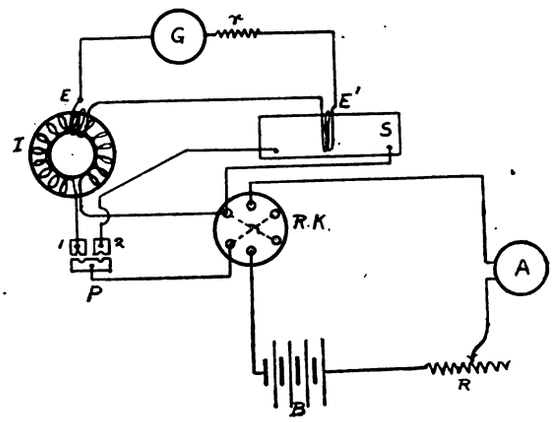

FIG. 3.—B, Battery of Accumulators; A, Ammeter; R, Adjustable Resistance; R.K, Mercury Cup Reversing Key; P, Two-way Plug Key; S, Solenoid; I, Iron Specimen; G, Galvanometer; E E', Exploring Coils.

To conduct the experiment, start with plug, P, in 2. Adjust current to a convenient value and reverse, noting throw of galvanometer. Repeat once or twice, and take a mean of the results. Now put plug in 1, and adjust current to such a value that H in the ring is the maximum we require. We may find this by comparing with other B-H curves of iron similar to ours. Reverse current several times, then take a reading of throw of galvanometer on reversing. Repeat this with a lower current, and so on, taking about a dozen points on the curve, and reversing current once or twice each time before taking the reading.

We have seen how to calculate the value of the flux N', which on being reversed in the solenoid gives a deflection *d'*; therefore, if we obtain a deflection, *d*, for reversing a flux, N, in the iron specimen, we know that

Digitized by Google

$$N = N' \times \frac{d}{d'} \times \frac{200}{10},$$

if, as we assumed, E' has 200 turns and E has 10 turns. Therefore B, which equals $\frac{N}{\frac{\pi d^2}{4}}$, can be calculated for any reversal of current, C, or for any value of H, since $H = \frac{4\pi}{10} \cdot SC$, and we may therefore plot a B-H curve. From this, knowing $\mu = \frac{B}{H}$, we may calculate the permeability and plot a permeability curve.

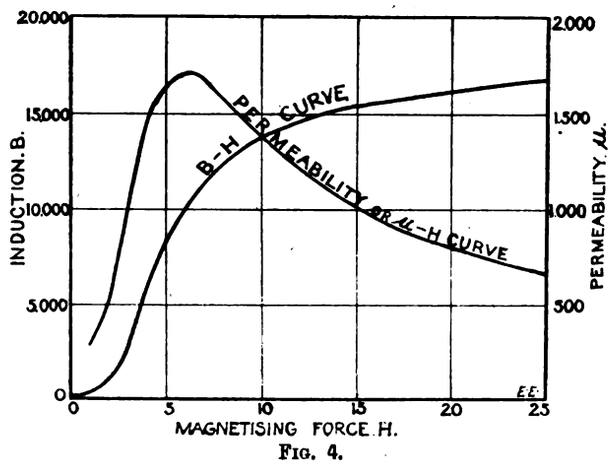

Fig. 4.

Fig. 4 shows curves of permeability and induction for a soft-iron ring.—W. S. P.

Answer to No. 707 (*awarded* 7*s.* 6*d.*).—The permeability of a sample of iron or steel in the form of a ring is measured in the following manner: A solenoid, S (Fig. 1), of known mean cross-section and length, and uniformly wound with

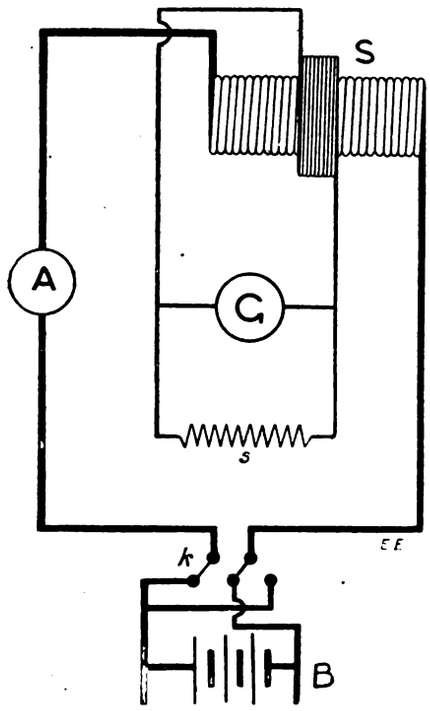

Fig. 1.

a known number of turns, is excited by a current from a battery, B, or other source. This current can be accurately measured by an ammeter, A, in the exciting circuit. Midway along this solenoid is wound an exploring coil whose turns are in series with a ballistic galvanometer, G; *s* is the galvanometer shunt. If the solenoid be excited and the exciting current suddenly reversed by means of the switch, *k*, the current induced in the exploring coil causes the galvanometer to give a deflection. Now, the deflection of the galvanometer will be proportional to the current induced in the exploring coil. This current is proportional to the E.M F. induced, which in turn is proportional to the number of lines of force linked with the exploring coil. Thus the galvanometer deflection is a measure of the number of lines of force linked with the exploring coil.

Let H = magneto-motive force required to produce a flux of one line per square centimetre in air;
N = number of turns in the exciting coil;
c = current in the exciting coil;
L = length of solenoid;
a = mean cross-section of exciting coil in square centimetres.

Then $H = \frac{4\pi N c}{10 L}$ = C.G.S. lines per square centimetre at the middle section of the solenoid, and

$\frac{4\pi N c a}{10 L}$ = total lines at middle section of the solenoid.

Now, if the number of turns in the exploring coil be *n* turns, then the lines of force linked with the galvanometer circuit will be

$$\frac{4\pi N c a n}{10 L} \text{ C.G.S. lines.}$$

The effect upon the galvanometer of reversing $\frac{4\pi N c a n}{10 L}$ lines is equivalent to creating $\frac{2(4\pi N c a n)}{L\,10}$ lines.

Let the deflection corresponding to this flux = θ degrees. Let R = ohms resistance in the entire secondary circuit; K = number of lines per degree deflection of the galvanometer, with *r* ohms resistance in the secondary circuit. Then

$$K = \frac{\frac{2(4\pi N c a n)}{10 L}}{\theta \times \frac{R}{r}}.$$ Let this = Y lines.

The galvanometer having been thus calibrated, we are in a position to measure the permeability of the ring sample under investigation. The ring is wound all over with an exciting coil of a known number of turns, N', its cross-section, *a'*, and mean circumference, L', having been previously ascertained. An exploring coil, Q (see Fig. 2),

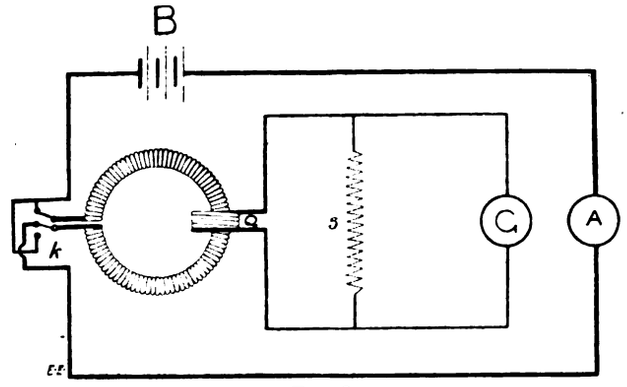

Fig. 2.

of known number of turns, *n'*, is then wound on it. The exciting current, *c'*, is measured by an ammeter, A.

Again, $$H = \frac{4\pi N' c}{10 L'}.$$

Let the total resistance of the secondary circuit = R'. Now let the current in the exciting coil be reversed and the deflection of the galvanometer noted. Let this deflection be θ' degrees. Now if the total resistance of the secondary circuit had been *r* ohms, and if there had been only one turn in the exploring coil, and if the flux had been simply created instead of reversed, we should have a deflection = $\frac{R' \times \theta'}{2 \times r \times n'}$. Let this equal D degrees. Consequently, since Y lines correspond to 1deg. deflection of the galvanometer, the flux reversed in the sample was D × Y C.G.S. lines. Since the cross-section of the ring is *a'* square centimetre, the density per square centimetre is

$$B = \frac{D \times Y}{a'}.$$

Digitized by Google

Let the permeability be represented by the Greek letter μ. Then

$$\mu = \frac{B}{H} = \frac{\frac{D \times Y}{a'}}{\frac{4\pi N' c'}{10 L}} = \frac{D \times Y \times 10 L'}{4\pi N' c' a'}.$$

For practical purposes the density is generally expressed in lines per square inch. Lines per square inch = 6·45 × lines per square centimetre. Ampere-turns per centimetre of length $= \frac{10 H}{4\pi}$. Ampere-turns per inch of length = 2·02 H.

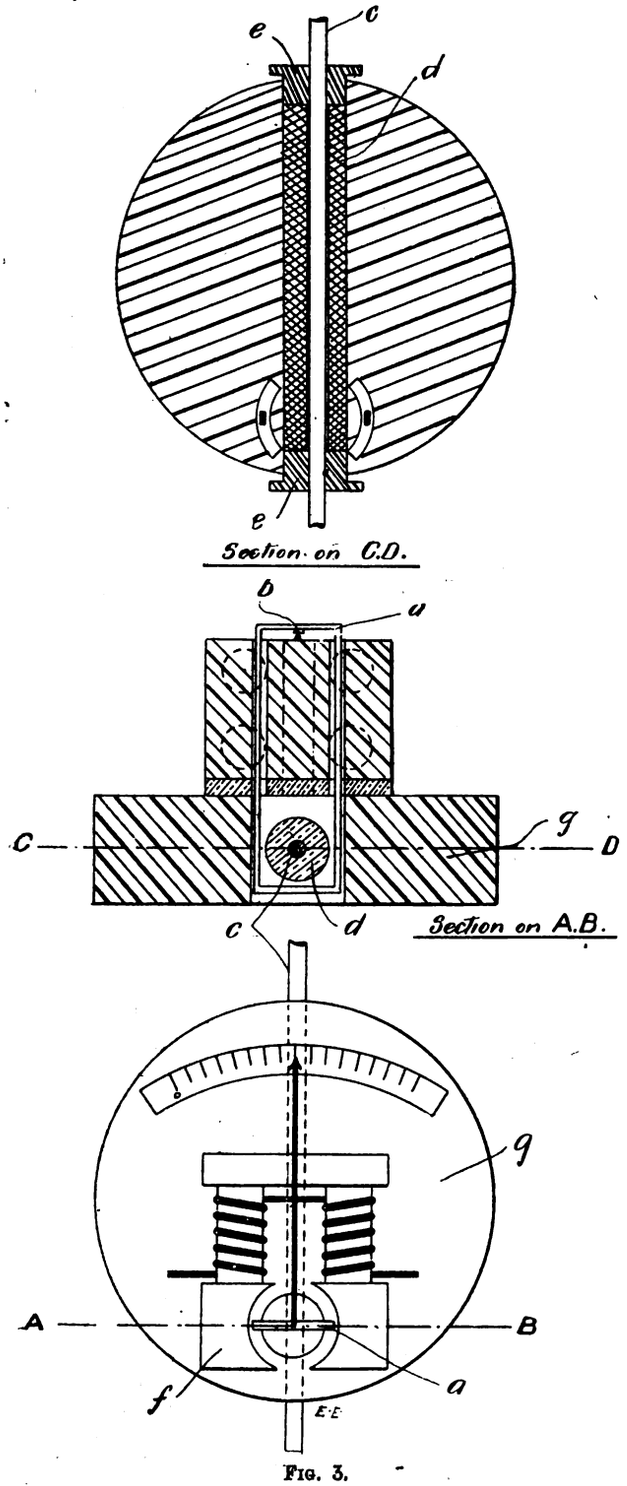

FIG. 3.

The foregoing method, although giving results of great accuracy, is a very lengthy and tedious process, owing to the necessity for winding the exciting and exploring coils afresh on each sample to be tested.

Permeability tests can be carried out much more expeditiously and with quite sufficient accuracy for all practical purposes by means of the instrument designed by Mr. Frank Holden. The general idea of this instrument is shown by Fig. 3. On a circular wrought-iron block, *g*, is mounted a magnet, *f*, constantly excited from any convenient source of current. Through the block, *g*, at right angles to its axis, passes a hole. In this hole a coil, *d*, is placed which surrounds the sample, *c*. Magnetic contact between the block and the sample is only made at the ends by means of iron plugs, which accurately fit the block. The sample is accurately turned to fit the holes in the plugs, *e e*. Suspended at *b* is a coil, *a*, consisting of one turn of copper wire. This coil surrounds the sample, *c*, and is free to move in the field set up by the constant magnet, *f*.

A sample is tested in the following manner. First the instrument is calibrated by inserting a standard bar whose permeability is known with precision; the pointer attached to the coil, *a*, is set to zero. The current in coil *d* is reversed, and the reversal of the flux through the bar, *c*, being interlinked with the coil, *a*, induces a current in it, and as the coil is at this moment lying obliquely across the field of *f*, it will deflect through a certain angle. This angle of deflection is directly proportional to the flux reversed. Let this deflection = θ degrees. The sample to be tested is now placed in the instrument, and a second deflection is obtained by reversing the current in *d*. Let this second deflection = θ'. Then, if deflection θ be known to correspond to flux N, then flux in sample under investigation is

$$= \frac{\theta' N}{\theta}.$$

If sectional area of sample is A square centimetres, then

$$B = \frac{\theta' N}{\theta \times A}.$$

The instrument is usually so arranged that H is a known multiple of the amperes in the coil, *d*. Let this constant = K. Let current in *d* = C. Then

$$H = CK,$$

and

$$\text{permeability} = \frac{\theta' \times N}{\theta \times A \times CK}.$$

In the above manner samples of iron or steel can be tested for permeability with a minimum of preparation of the sample, and with a high degree of accuracy and celerity. One excellent feature of Mr. Holden's instrument is that it is entirely unaffected by any external stray field.—T. E. G.

Question No. 708.—On a four-pole, 200-ampere, 500-volt B.T.H. three-phase rotary converter, the attendant when running the machine up as a direct-current motor left the shunt field switch open, and machine ran up as a series motor, but in the opposite direction to that in which it runs as a shunt machine. Are the shunt and series windings connected up properly? If not, what is the best method to find out which way the coils are wound without uncovering the windings, and how should they be connected up? P.S.—The shunt coils are joined up two in series.

Best Answer to No. 708 (*awarded* 10*s.*).—The shunt and series windings on the machine in question are connected up quite correctly, and the attendant was lucky not to have had a nasty accident due to the series winding being also cut out. It is evident from the data given that the machine is intended to run as a shunt motor and as a compound-wound generator. The explanation which "Herions" seeks is best found by considering the machine in its different aspects—as a shunt generator or motor, and as a series generator or motor. In dealing with motors, there are one or two points which, if borne in mind, will give a simple solution to apparently intricate problems. When a conductor carrying a current is placed in a magnetic field and is free to move in that field, it will be impelled in such a direction that the E.M.F. induced in it by this motion will oppose the flow of the original current in the conductor. Now consider the machine in question as a shunt generator. Referring to Fig. 1, it will be seen that when running as a shunt generator the machine sends a current from B+ (positive brush) to terminal, T+, round the outside circuit, and back through terminal, T−, to machine by the negative brush, B−. Part of the current also goes from terminal, T+, through shunt resistance, S R, and field switch, F S, through the shunt field winding, Sh. F, to D, and back to machine at B−, the field thus shunting some of the armature current. Now, without altering any connections, consider the machine as a shunt motor. Current now *enters* at

Digitized by Google

T+, and flows through B+, through armature, A, and back to the mains *viâ* B− and T−. Part of the current also flows from T+, as before, through S R and F S, through shunt field, Sh. F, to D, and back to mains, *viâ* T− (*i.e*, the current in the field flows in the same direction). Now the machine is running as motor, as it did when the machine was running as a generator, the difference being that the field now shunts some of the line current. Obviously, if the law stated above is to be obeyed, the machine must run in the same direction as a motor as it did as a generator, in order that the E.M.F. induced in the armature conductors by their motion shall oppose the flow of the current originally existing in the conductors and entering at T+. Now consider the machine as a series generator. Referring to Diagram 2, when running as a generator current is sent from B+ up through series field, Sr. F, to T+, round outside circuit, and back to the machine, *viâ* T− and B−. Now without altering any connections consider the machine to be running as a motor. Current now *enters* at T+ and flows *down* through series field, Sr. F, into armature, A, *viâ* brush, B+, and back to

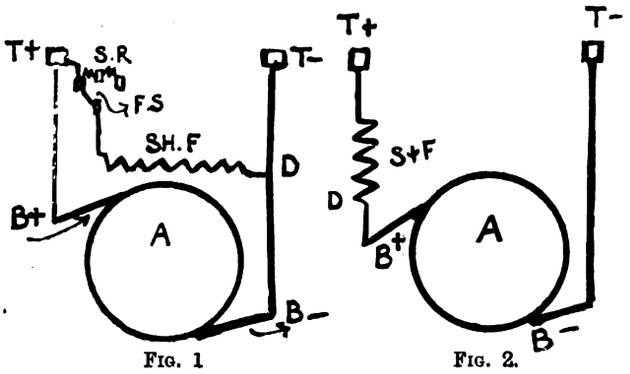

Fig. 1

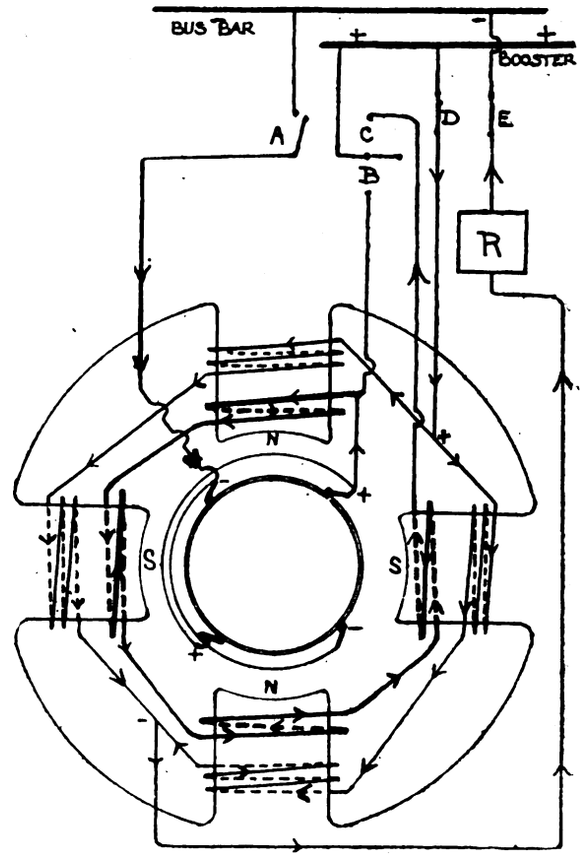
Fig. 2.

mains by B− and T−. It will be observed that the current through the field is in the reverse direction to when the machine was running as a generator; therefore, in order that the armature conductors may have an E M.F. induced in them by their motion, which will oppose the flow of the current entering at T+ and taking the course described, the machine must revolve in the opposite direction when running as a motor to what it does when running as a generator. This will explain why a shunt machine must (with the connections unaltered) run in the same direction as a generator, or as a motor, and why under similar conditions a series machine will run in the reverse way as a motor to what it does as a generator. The crux of the matter is that, when running as a motor, either type of machine must also generate an E.M.F. which opposes the flow of the entering current. In order to test the direction in which coils are wound, test the coils by means of a couple of dry cells and a galvanometer, put the cells across D and F S, and then put the galvo. leads across the same points and note the direction of the deflection. Now place the cell lead which is on D, 1, on D in Diagram 2, and the other lead from the cells at the top terminal of the series winding. Then treat the galvo. leads in the same way, and if the deflection is the same, then both coils are wound in the same direction.—W. T. W.

Answer to No. 708 (*awarded* 7*s.* 6*d.*).—The accompanying sketch shows the usual method of connecting up a machine such as the one in question. When running as a compound generator (all switches closed except B), the currents in the field windings would flow in the direction of the arrows, and the magnetic fields produced would be as indicated by the letters. Now consider the machine without the shunt windings (switches D and E open) being run up to speed as a series motor. The polarity of the brushes is the same as before, but the current in the field windings (series) being in the opposite direction, produces a reversed field, and consequently the machine runs in the opposite direction. The best method of verifying the field connections is by means of an exploring coil, consisting of two or three turns of wire wrapped round the pole-piece and connected in circuit with a galvanometer. On making the shunt circuit a current will be induced in the exploring coil, causing a kick on the galvanometer. This kick will be to the right, say for one pole, and to the left for the next, and so on, taking the poles in order right round the machine. The series turns may be tested similarly. Connect them across the 'bus bars through a rheostat and a switch, and arrange to pass a fairly large current. Proceeding exactly as with the shunt windings, the kicks should, if the connections are correct, be in the same direction for each pole as those given by the shunt wind-



ings. It will probably be found necessary to increase the turns on the exploring coil when testing the series coils.—W. E. P.

Answer to No. 708 (*awarded* 5*s.*).—Apparently the series winding is properly connected. When the machine is working on load, the function of the series coil is to increase the magnetisation as the load increases—that is, it is wound to give a field similar to the field due to the shunt winding. If the rotary be started as a direct-current motor, the current flowing through the armature and series coil will be in the opposite direction to the normal, therefore it will oppose the field due to the shunt winding. As the starting current is usually small, the magnetisation due to the series coil will be small, and have very little neutralising effect on the main field. If, however, the shunt field switch be left open when starting, the magnetisation passing through the armature will be that due to the series coil, which, being in the opposite direction to the normal, will establish a field passing through the armature in the wrong direction, consequently the machine runs in the wrong direction, taking a very heavy starting current. It is good practice with compound rotaries arranged for starting as direct-current motors to provide a means of cutting out the series coil, thus getting a stronger field; consequently less starting current is required. To ascertain in which direction the field coils are wound, it is only necessary to note the polarity of the particular pole-piece on which any coil is placed, then, looking at the pole-face, the current will flow clockwise if it be a north pole, counter-clockwise if it be a south pole.—H. W.

AUGUST 19, 1904.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

QUESTIONS.

717. A high-speed lighting set of 200 h.p. when working at full load requires 160lb. steam in steam-chest, but at three-quarter load only 120lb. is registered on the pressure gauge connected to it. The engine is controlled by throttle valve, and runs condensing. Which should be the most economical boiler pressure to use (as regards coal consumption) for continuous runs at three-quarter load—165lb. or 130lb., and why? Does superheating by 100deg. affect the case?—H. G. V.

718. How would you calculate the magnet and winding of a maximum and minimum release and magnetic brake (*a*) for direct current, (*b*) for alternating current.—J. B.

719. In an alternating-current plant with rotaries a bad phase was made when synchronising another alternator with one previously running, and which caused all the rotaries to loose their fields. The same thing has happened when a bad phase has been made in synchronising a rotary. Could anyone explain in full detail exactly what happens to the rotary as to how it looses its field?—F. B.

ANSWERS.

Question No. 709.—The proprietors of a boarding-house have a small hand-worked lift for elevating and bringing down dinners, etc. It is desired to work the lift electrically. What would be the best method of doing so, so as to obtain the following conditions: The switching gear must be of the simplest, and be easily understood by the servants, and, of course, be fool-proof. It must be actuated from either top or bottom. The lift is balanced, and it is required to take up at full load about 1cwt. of utensils, etc.; silent working is specially desired. Capital cost to be kept as low as possible. Skilled labour is available to do the whole of the erecting and wiring, but not to supervise after the job has been set to work. A supply of energy at 230 volts is available, and there is an electric bell service from top to bottom of lift.

Answer to No. 709 (*awarded* 10*s.*).—Dinner lifts worked by electricity, though not common, are in use in a good many places in the country, chiefly, of course, in large buildings and such places where there are a lot of things to bring up for the table. I hardly see the electric bell service which is at present from top to bottom of the lift will be of any use to us, as the insulation on the wires and the method they have probably been run would most certainly not be good enough to stand a pressure of 230 volts. The methods I shall indicate will be quite feasible, but any calculations made can only indicate the methods to be followed, and "W. T. W." must adopt this method to this particular case himself, as he has given no particulars about the lift itself. He says it is to be capable of lifting 1cwt., and it is balanced. Now, the lift itself, to hold 1cwt of goods, must be a fair size, and must be built substantially; and so let us assume the box itself into which the articles are put, together with the metal rings to which the suspension ropes are attached, weighs ½cwt. Now, as to the counterweight, it is not said what weight this is. Is this ½cwt. as well? in which case the lift itself is exactly balanced, and our motor will have to be capable of raising 1cwt.; or is the weight of the counterweight greater? in which case we should never have such a heavy load to elevate. The most economical size of counterweight would be to make this 1cwt. in weight, for then the maximum effective load to be raised cannot be more than ½cwt. This may very easily be seen from the following: It is evident that the greatest load must be when 1cwt. of utensils is being raised, and also when the lift is being dragged down against the action of the counterweight, for in the first case we have the total weight of utensils and lift cage is 1cwt. + ½cwt. = 1½cwt. Against this has to be put the weight of the counterweight, which is 1cwt., and hence the total effective weight to be raised is $1\frac{1}{2} - 1 = \frac{1}{2}$cwt. Similarly, when the lift is being drawn down against the counterweight empty, the weight of the cage alone is ½cwt., and the counterweight is 1cwt. Hence total effective weight to be raised is $1 - \frac{1}{2}$cwt. = ½cwt. From this I think "W. T. W." will see that the most economical weight for the counterweight to be will be 1cwt, as if any other value be taken and similar calculations be made, it will be found that either in one or the other of these cases the total effective load to be raised will be greater than ½cwt., and the rule for the best weight for the counterweight will be readily seen to be equal to the weight of the lift cage plus half the weight of the maximum load. Let us now assume the total lift required is 10ft., and the time to be taken for the complete lift from rest at the bottom to a position of rest at the top is eight seconds, and that it takes the motor three seconds to get up to top speed, three seconds to slow down from this to position of rest, which leaves two seconds for the motor to be running at full speed. Now let us further assume that during the three seconds it takes to get to full speed the speed is one-third full speed at the end of one second and two-thirds full speed at the end of the second second, and that this rate of acceleration is the same when stopping, though, of course, this time it is in the negative direction.

Let x = full speed in feet per second of lift.

Speed at end of one second $= \frac{x}{3}$

" " two seconds $= \frac{2x}{3}$

" " three " $= x$.

Distance travelled in 1st second $= \frac{x}{3 \times 2} = \frac{x}{6}$

" " 2nd " $= \frac{x}{3} + \frac{x}{6} = \frac{x}{2}$

" " 3rd " $= \frac{2x}{3} + \frac{x}{6} = \frac{5x}{6}$

" " 4th " $= x$

" " 5th " $= x$

" " 6th " $= \frac{5x}{6}$

" " 7th " $= \frac{x}{2}$

" " 8th " $= \frac{x}{6}$

} Being same as those during acceleration.

Now the sum of these must be equal to 10ft., the total length of lift. So

$$\frac{x}{6} + \frac{x}{2} + \frac{5x}{6} + x + x + \frac{5x}{6} + \frac{x}{2} + \frac{x}{6} = 10\text{ft.}$$

Hence $x = 2{\cdot}4$ft. per second, which is greatest speed of lift.

Total effective load = ½cwt. = 56lb., with 1cwt. in lift.

Power to raise load of 1cwt. in lift at top speed $= 56 \times 2{\cdot}4 = 134{\cdot}2$ foot-pounds per second = ¼ h.p.

This ¼ h.p. is entirely neglecting friction and the inertia of the whole system, and is only the power required to keep the system in motion after it has been accelerated up to full speed, and does not take into account the power required to accelerate the load from rest up to full speed in three seconds. This power required will be much greater, and I should advise using either a ½-h.p. motor, or, better still, a 1-h.p. motor, the difference in prime cost being only a matter of about £5, and the larger power motor will work far better and will run up to speed quicker. If the balance weight on the lift is only equal to the weight of the cage, it will be absolutely essential to use the 1-h.p. motor.

A small motor of this size will run at a speed of about 1,300 revolutions per minute, and so, of course, this must be geared down. This may best be accomplished by means of a pinion and spur wheel, the latter being on the same shaft as the winding drum. A suitable sized pinion wheel on the motor spindle will be about 2in. diameter, and a suitable sized winding drum will have a diameter of about 6in. It will be necessary to have the drum grooved, so that the rope will wind up on to it easily. A suitable depth would be to make the grooves about as deep as half or three-quarters the diameter of the ropes. The above 6in. diameter of drum means the diameter of the drum and half the thickness of the rope each side, being the diameter of one turn of the rope round the winding drum.

Digitized by Google

Now, 6π = length of one turn of rope in inches and $\frac{10 \times 12}{6\pi} = 6{\cdot}36$ = number of turns of drum to wind lift from bottom to top.

There will be three ropes to wind on to this drum, two being for the lift and one for the counterweight, each of which must have a groove cut for it.

Now, going back to the former assumptions, that the speed of the lift, and hence the motor, is $\frac{x}{3}$, $\frac{2x}{3}$, and x in both the first and last three seconds of the run, and knowing the full speed of the motor is $\frac{1{,}300}{60} = 22$ revolutions per second.

Now, total revolutions in 1st second = 3·66 and also in 6th
" " 2nd " = 11 " " 7th
" " 3rd " = 18·33 " " 8th
" " 4th " = 22 " " 5th

Now, summing up the total number of revolutions of the motor armature for the eight seconds' lift, we get 110.

Now, as there is a 2in. pinion wheel on the end of the spindle running 110 revolutions, driving on to a spur wheel running 6·36, the diameter of this spur wheel must be equal to 34·6in. This is certainly very large, and the only way to reduce it, except by another reduction, which would increase the cost and lessen the efficiency, would be to reduce the winding drum diameter to 4in. instead of 6in.

Length of one turn now = 12 6.

Total number of turns for hoist = 9 53.

Then diameter of spur wheel = $\frac{110 \times 2}{9\ 53} = 23$in.

This is a far more practical size, though 4in. diameter for the turns of the rope is certainly very small, and undoubtedly a double reduction would be best.

Now, the method of procedure will be the following: The motor will be placed either at the top or the bottom of the lift well, and will drive by means of the pinion and spur wheel on to a countershaft extending centrally across the well, and holding the winding drum. Lifting ropes will be attached at either end to this drum in the aforementioned grooves, which ropes extend up the sides of the well, over pulleys at the top, down again, fastening into two eye hooks fastened centrally on the top of the lift itself. Another rope will be fastened round another groove placed centrally in the winding drum, go round a pulley at the side of the bottom of the well, up the side to the top, over two other pulleys, across, and down again, the other side fastening on to the counterweight. Of course, it must be arranged that when the lift is at the bottom the counterweight is at top, and sufficient rope must be wound on the drum at the bottom of the well so that when the lift is at the top the rope may have unwound and let the counterweight down to the bottom. Some strong spring buffers should be attached to the sides of the well, both at the bottom and at the top, a little beyond the usual travel of the lift, so that if the lift runs too far it may not have a violent shock in stopping. It is necessary to have a brake so that the lift may stop in any position when required, and not be pulled up by the counterweight when empty, nor down by the load in the cage when full. This should be quite automatic in action, going on when the motor stops and coming off the moment it starts. This can best be accomplished electrically, using a solenoid, which by drawing in its core releases the brake. Fig. 1 shows such a solenoid and brake; its action may be easily seen. The plunger is attached to the junction of two links, which normally incline downwards to this junction. On their other extremities are pivoted two pieces of metal to which the brake blocks are attached, and the other ends of these metal arms are bent inwards and pivoted together. The plunger is coned at its top end and fits into another piece of soft iron, which is permanently fastened inside the solenoid. The object of coning this plunger is double: firstly, by so doing we increase the area of the air-gap and so decrease the reluctance and get more lines through the core; secondly, by doing so we get the effect of having a long pull with only a slightly varying length of air-gap, which would not be the case if the two surfaces were to be flat. When current passes round the solenoid coil the plunger is pulled up, which brings the two links horizontal, and so pushes their other extremities outwards and takes the brake pieces off the drum. This brake drum is keyed on the same shaft as the winding drum. The solenoid is

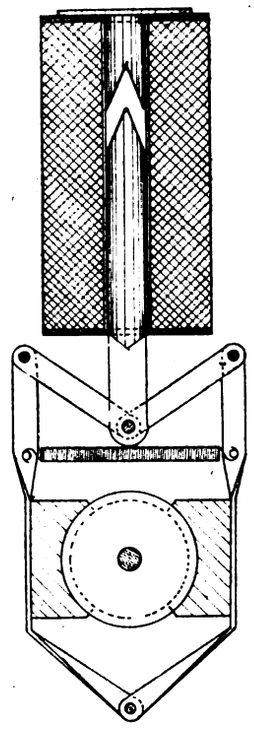

FIG. 1.

connected across the mains as a shunt to the motor, so that when the motor is switched on the solenoid is energised, and takes the brake off the winding drum, so releasing everything and allowing the motor to do its winding freely.

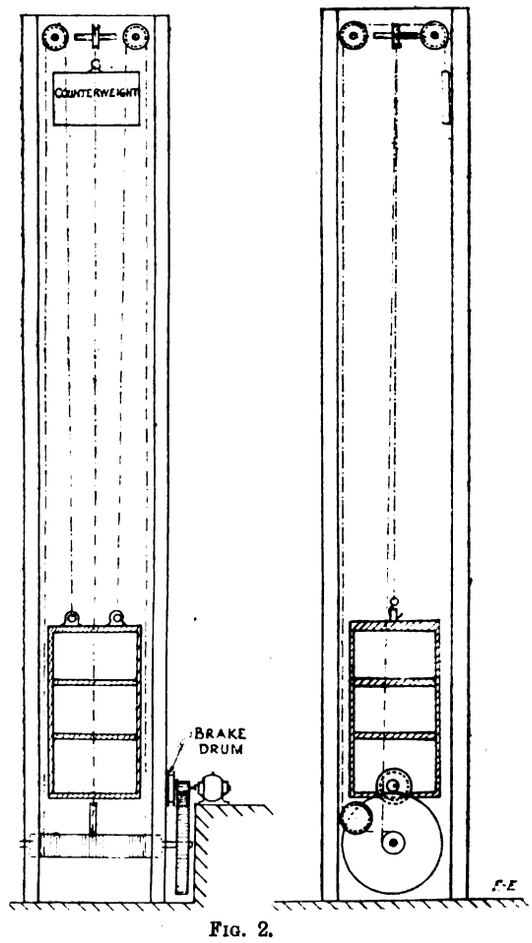

FIG. 2.

Another necessity is to have some means by which a person operating the lift from where they are to the other stage may know when the cage is there, and so may be enabled to switch off and put the brake on at the correct moment.

Digitized by Google

This might, of course, be done electrically by having a system of brushes on the lift cage itself, and strip brass contacts on the side of the well running the greater part of the whole distance of travel, but stopping abruptly at the place where current should be switched off. If the main motor current passed through these contacts and brushes, it would automatically be broken at the correct time to stop the lift at the proper position, but I think this electrical method is hardly advisable, owing to the extra cost it would entail, the extra likelihood of something going wrong, and also, probably, the fire insurance people would object to these live unprotected contacts being broken thus. A better method would be to mark the positions of the counterweight on the side of the lift wells at which points it is necessary to switch off, and then when running the lift to watch till the counterweight reached this spot, and then immediately open the circuit. Fig. 2 gives an idea of the general arrangement of the dinner lift, which is fairly self-evident from the aforegoing description of the parts, as I have given two elevation views with the front sides removed in both cases, and in one case the motor not shown in its end

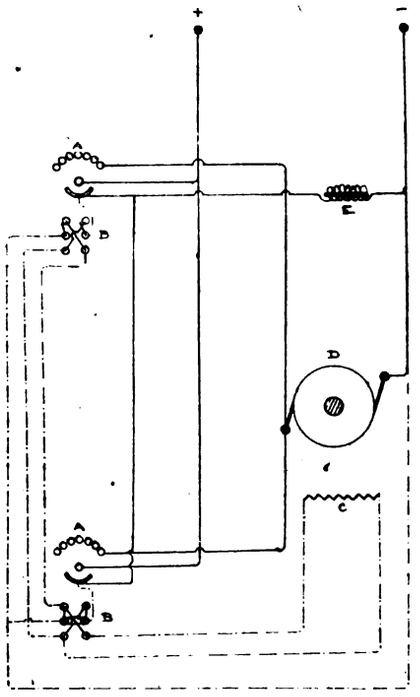

FIG. 3.

view. Fig. 3 gives a diagram of all the necessary connections, where A is a small starting switch suitable for this size of motor, and having a resistance of about 40 ohms when all the contacts are in circuit. Considering the short time the motor is to run, it will be necessary to switch on quickly over all the contacts, only occupying about one second for the whole operation. B is an ordinary double-pole reversing switch, C is the shunt winding of the motor, and D the armature. Of course, a pair of double-pole switches and fuses might be put in across the mains if required. On careful examination of these connections, it will be seen that to work the lift motor it is necessary to first close the reversing switch in either the up or the down positions as required, and so making the shunt circuit, and then on operating the starter, A, the motor will run, as this finally closes both the armature and the field, and finally rapidly switching off at A, so de-energising the brake solenoid and putting the brake on, and then opening the reversing switch. The current enters the starter arm at the point where it is pivoted, the armature current passes through the resistance contacts, and the shunt passes through the back ring, it being arranged that the shunt is not made at this point till just before the lever touches the first contact; this is to prevent the shunt being always on, and it also has it fully magnetised so as to keep up a good torque, and hasn't been arranged to put the armature resistances in the shunt circuit when full on, as is often the case. To reverse a shunt motor, it is only necessary to reverse the direction of the current through the field winding. This is accomplished by throwing over the reversing switch to the other side. The brake solenoid shown diagrammatically at E is also connected across this back ring and the negative wire, so that it is energised and takes off the brake the moment the motor circuit is closed. It is absolutely necessary to open the reversing shunt switch after switching off the motor, as otherwise if it be left in, say, in the up position, the lift will be at the top, and now if someone comes to the bottom and wants it down there they will put their reversing switch in the down position, which will result in a short-circuit and blown fuse, which may readily be traced out. If, however, two persons switch on at the same time, both trying to send the lift in the same direction, it will go, and nothing serious will happen. It is very important to impress on the servants the necessity of always leaving this reversing switch out. Of course, it might be argued that it would have been better to have used a series motor so as to have taken advantage of the greater starting torque, but I hardly think this to be advisable, as if the lift starts too suddenly things are very likely to get spilt; hence the use of a shunt motor, which starts steadier and is steadier running.

Another cheaper method of operating this lift, which, however, I think hardly as good as the one I have described, would be to have the shunt motor running in one direction all the time the lift were likely to be required. Have a very long pulley on the motor driving on to a countershaft with the winding drum on by means of three pulleys, one fast on the shaft with a loose pulley each side, each with a belt on going round the motor pulley, one belt being crossed. Now, striking gear might be operated by ropes running up the side of the lift well, which would pull either the straight or the crossed belt off its loose pulley on to the fast one on the countershaft, and so turning the winding drum. Another kind of brake would have to be devised if this were to be the system used for operating the lift. A simple starting switch is all that is required to run the motor up to speed. I should, however, strongly advise the use of the former method described, and if the pinion wheel be of rawhide, I don't think it should make much noise. Such an electrically-operated lift would require practically no attention except just for lubrication occasionally.—E. R. ALEXANDER.

Answer to No. 709 (*awarded* 5*s.*).—The hoisting gear which would probably best meet the specified conditions—viz., cheap, silent, and fool-proof—is shown diagrammatically in Fig. 1. A compound-wound direct-current motor, *a*, designed to give ¾ h.p. at 400 revolutions per minute is direct connected by means of a coupling, *b*, to a small hauling drum, *c*, 1in. diameter, running in two plummer blocks, *d d*. On the same shaft is a brake wheel, *e*. The hoisting rope is given about half a dozen turns round the drum, *c*, which should give sufficient grip to raise a load of 1cwt. The drum should be merely rough turned, and not polished at all. On the other end of the rope is hung the balance weight, *f*. Thus the rope is always kept tightly coiled round the hauling drum. A quick-break, double-throw, double-pole switch, *g*, provided preferably with carbon break, is fixed in a suitable and accessible position on the side of the lift well. This switch must be designed so as to have a well defined "off" position. Stretched down the lift well is a cord, *h*, kept taut by tension springs, *k k*, at top and bottom anchorings. On this rope are two knurls, *l* l_1. Fixed between two brackets on the side of the cage is a round iron pin about 15in. long. Free to slide up and down this pin is a wooden block, *m*, normally held in approximately a central position by the spiral compression springs, *n n*. In the block is a hole, through which the rope, *h*, passes freely. This rope is rigidly connected to the handle of the switch, *g*, in such a manner that in its normal position (as determined by the springs, *k k*) the switch is in the "off" position. On the drum shaft and beyond the brake wheel is a small centrifugal governor, *o*, so adjusted that at about 100 revolutions per minute it will cause the forked arm, *p*, to dip into the mercury-cups, *q q*, thus short-circuiting a starting resistance, which is placed between the two cups and is in series with the motor armature winding.

Digitized by Google

Fig. 2 shows the arrangement of the hand-brake. Round the brake wheel passes a steel band, preferably lined with segmental blocks of hardwood. The ends of this band are attached to the lever, *r*, which is pivoted at *s*, and at the

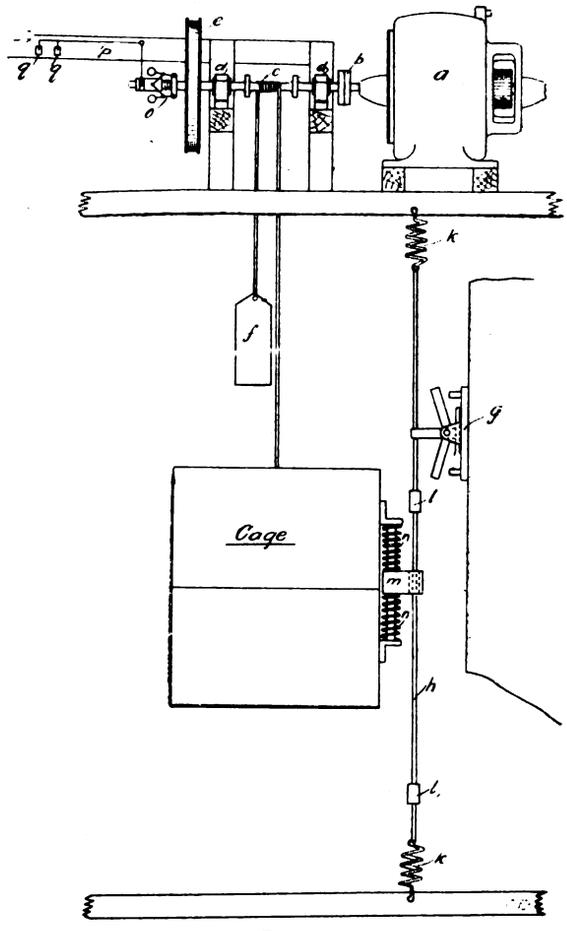

FIG. 1

other end carries a weight, *t*. Immediately over this weight is fixed a pot magnet, *u*, which, when fully excited, has sufficient lifting power to raise the weight, *t*, and so release the brake. The windings of this magnet are arranged in two parts, which are so proportioned that when the current

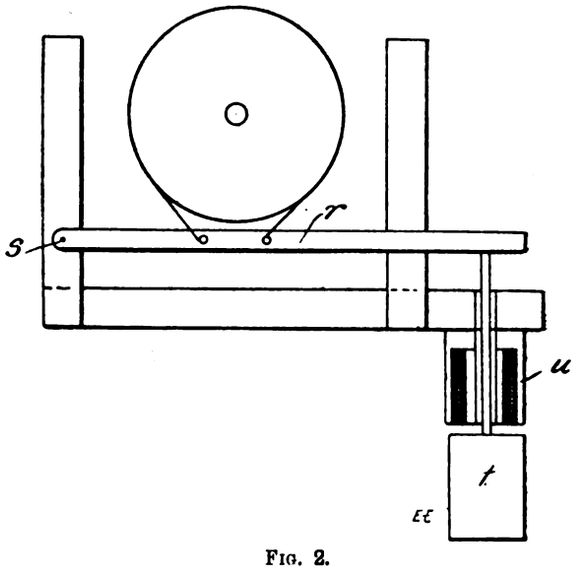

FIG. 2.

in the motor armature is reversed the current in 25 per cent. of the exciting coils is reversed, thus reducing the total excitation and the lifting power of the magnet to approximately one-half of its full strength, which leaves the brake half on when the cage is being lowered, which will prevent it coming down at a dangerous speed.

Fig. 3 is a fairly self-explanatory diagram of the electrical connections. M is the motor armature, S the series field, *s* the shunt field, which need not be more than 30 per cent. of the total ampere-turns, and is only intended to prevent the motor running away on light loads. C C are the two parts of the brake magnet exciting coil, which are always in series with the motor armature winding; *g* is the D.T. D.P. switch, R is the starting resistance, and *q q* are the mercury-cups through which the starting resistance is short-circuited by the action of the centrifugal governor above described; Q is a Thomson magnetic blow-out circuit breaker, provided to take care of overload. The switch, *g*, is so coupled up that pulling down the cord, *h* (Fig. 1), starts the motor in the direction for hauling up the cage, while pulling the cord

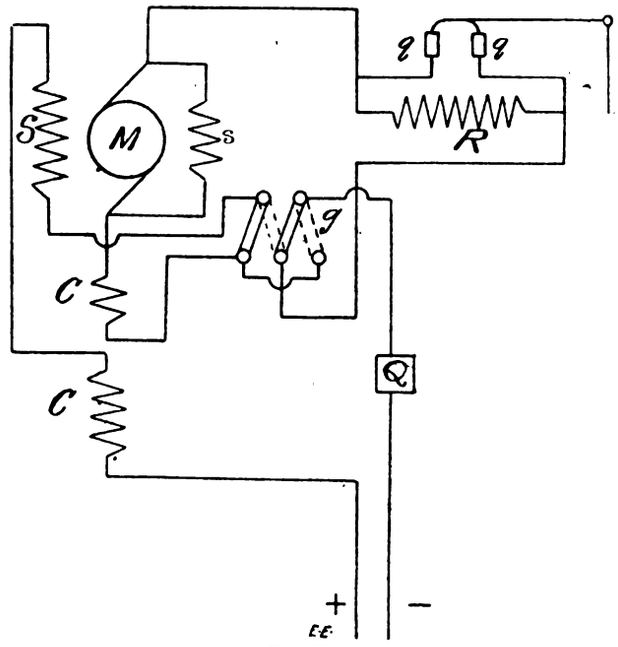

FIG. 3.

upwards causes the cage to descend. This arrangement prevents risk of injury to the operator should he continue to grip the cord until the cage comes right down or up, as the case may be; for his hand will be struck by the block, *m*, and the rope pulled the proper direction to reverse the motor, and so cause the lift to move away from his hand. When the cage is up to the desired height, the block, *m*, engages with the knurl, *l*, pulling up the rope and opening the switch, *g*, cutting off the current from the motor and also from the brake magnet, thus allowing the weight, *t*, to pull the band tight round the brake wheel, bringing the drum to a dead stop. When the cage is descending, the knurl, l_1, is struck and the cage brought to a standstill as above. A very slow-speed motor has been chosen to avoid the need of gearing, thus reducing noise and attendance to a minimum figure. As the duty is very intermittent, a pretty tightly-rated motor can safely be installed, sparking rather than thermal considerations being the limiting factor. Thus, although being very slow speed, its cost will probably be less than that of a higher-speed motor and worm gearing. Toothed gear would be inadmissible on the score of noise.

The equipment described above could probably be all provided and fixed for not more than £40. It is as simple a gear as could safely be installed to do the work, and is as near fool-proof as any electrical apparatus can be, and, moreover, should be absolutely silent. With a winding drum 1in. diameter and running at 400 revolutions per minute, the lifting speed would be about 100ft. per minute. A higher speed than this would be likely to result in culinary compounds being served up which were not originally included in the menu.—T. E. G.

[Other replies to Question No. 709 will be given in our next issue.—ED. *E. E.*]

Supplement to "The Electrical Engineer,"
AUGUST 26, 1904.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

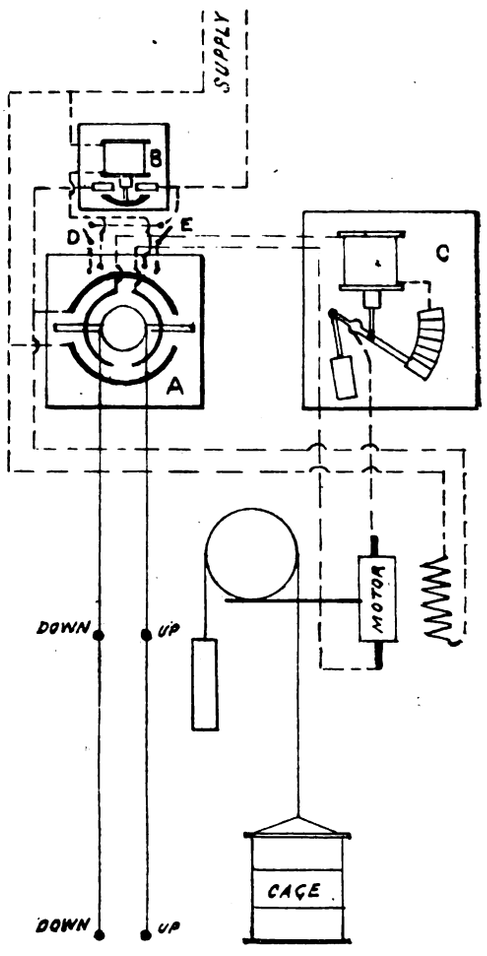
QUESTIONS.

720. In a certain type of coking stoker the bars are subjected at the back end to a very intense heat and soon burn away, resulting very often in serious damage to the stoker, due to them falling. The bars supplied by the makers are of a low-grade cast iron. What should be the composition of the iron in order, as far as possible, to resist the intense heat?

ANSWERS.

Question No. 709.—The proprietors of a boarding-house have a small hand-worked lift for elevating and bringing down dinners, etc. It is desired to work the lift electrically. What would be the best method of doing so, so as to obtain the following conditions: The switching gear must be of the simplest, and be easily understood by the servants, and, of course, be fool-proof. It must be actuated from either top or bottom. The lift is balanced, and it is required to take up at full load about 1cwt. of utensils, etc.; silent working is specially desired. Capital cost to be kept as low as possible. Skilled labour is available to do the whole of the erecting and wiring, but not to supervise after the job has been set to work. A supply of energy at 230 volts is available, and there is an electric bell service from top to bottom of lift.

Answer to No. 709 (*awarded* 5*s.*).—The accompanying sketch shows the necessary switches and connections for



the automatic control of a ½-h.p. reversible shunt-wound motor, operating 1cwt. lift balanced for average load. The method of operation is as follows. The attendant pulls the cord for up or down motion, whichever is desired, and this actuates switch A, which makes the proper connections to armature of motor and then closes solenoid-controlled main switch, B, and the motor commences to revolve, switch C cutting out resistance from armature circuit of motor as it comes up to speed. Switches D and E are geared to motor shaft, so that when it has made the requisite number of turns to bring cage to top or bottom gate, the main switch is opened and motor stops. When the cage is at the top gate switch D is open and E closed, so that the attendant can only start the motor in proper direction for taking cage downwards. The whole of the apparatus can be purchased in a compact form from a number of leading motor-control specialists, and can be erected and put to work by an ordinary wireman. It would be well to have doors for gates actuated by the cage, so as to prevent such an occurrence as attendant looking for cage and getting trapped.—A. T.

Question No. 710.—Controller required for a three-phase motor, 6 h.p., 100 volts; ratio of turns, 2 : 3; periodicity, 60. Work out diagram of connections and main dimensions of controller, supposing it were for lifting purposes on a crane.

Best Answer to No. 710 (*awarded* 10*s.*).—The general diagram of connections of a suitable controller are given in Figs. 1 and 2, in which Fig. 1 gives a development and

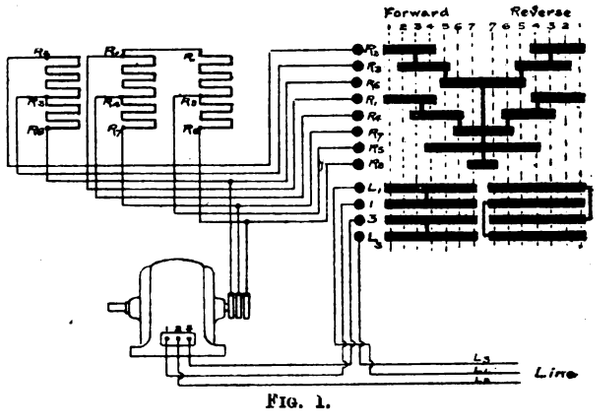


FIG. 1.

controller wiring, while Fig. 2 gives the connections corresponding to each "notch" of Fig. 1. It will be seen that the controller is of the reversing type, with one cylinder, the latter being capable of movement in two directions. This type of controller is to be preferred for controlling

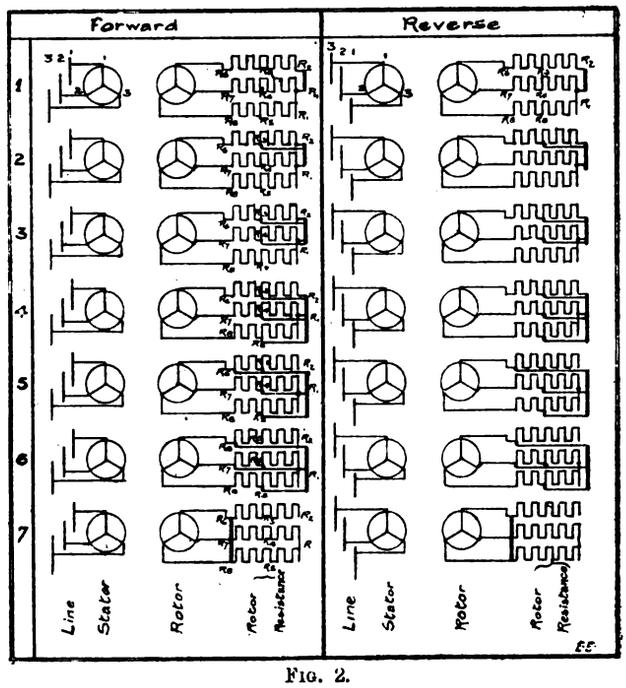

FIG. 2.

cranes, especially if it is worked from the floor level by means of a chain, since extra complication and confusion is involved by the type having the reversing cylinder separate from the main cylinder.

It will be assumed here that the rotor has a Y-connected winding, the rotor resistances likewise being connected in Y. This is the general practice, though for small motors some

Digitized by Google

manufacturers use a two-phase winding for the rotor. However, the type of rotor winding can easily be ascertained for the present motor, by open-circuiting the rotor and applying three-phase current to the stator. The voltage across each pair of slip-rings should be measured, and for a three-phase rotor these should be practically equal, while for a two-phase rotor two readings should be equal, and the third approximately $\sqrt{2}$ times each of the other readings. With two-phase rotors it is the general custom to connect one end of both phases together to one slip-ring, the other ends being connected to the remaining two rings. When connecting up resistances they should be joined up in a similar manner, the middle or neutral point going to the slip-ring corresponding to the same point in the rotor winding. Figs. 1 and 2 are drawn out for a three-phase Y-connected rotor, there being in all seven notches, though the resistance per phase is only divided into two steps. This is accomplished by cutting out resistance consecutively in each phase instead of simultaneously. The slight dissymmetry thus introduced occasions no difficulty; in fact, this method has the advantage of reducing the number of contact fingers in the controller to a minimum. The upper portion of the cylinder in Fig. 1 controls the rotor resistances, while the four lower contacts, designated by L_1, 1, 3, L_2 respectively, are for the purposes of reversing, and are connected in the stator circuit. For reversing a two or three phase motor all that is required is the leads of one phase to be changed over, which is accomplished by interconnecting the last-mentioned

FIG. 4. FIG. 5.

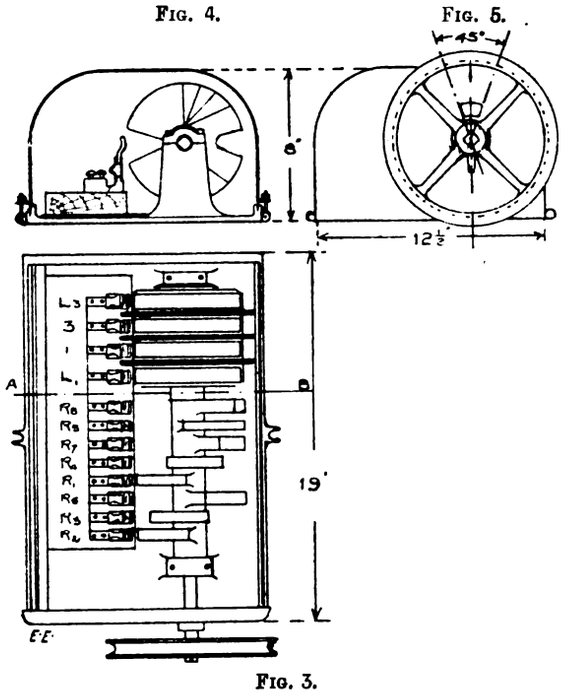

FIG. 3.

contacts as indicated in Fig. 1. Each of these contacts should, of course, be insulated, but the upper contacts must be all connected together. With the help of Fig. 2 all the notches of Fig. 1 can be easily followed.

The general construction of this controller is shown by the sketches in Figs 3 to 6; Fig. 3 being a plan with the cover removed, showing the general assembly; Fig. 4 an end elevation with front end removed; Fig. 5 an end elevation of controller complete; Fig. 6 a sectional elevation, taken on line A B (Fig. 3); and Fig. 6A a detail of the contact fingers. The body for the contacts R_1 to R_8 may be a brass casting, with facings of copper screwed on. In setting out this, the various angles for "off" position, first notch, etc., should be decided on, and the circumference of cylinder developed flat. The contacts, L_1, 1, 3, L_2, may consist of copper strips screwed on the circumference of a cylinder of hard wood, these being interconnected as in Fig. 1. Details of the contact fingers are indicated in Figs. 6 and 6A, and it should be mentioned that the copper connecting the finger to the body of the terminal should be fairly flexible. The dimensions are intended to give approximately the over-all sizes, etc., and will vary slightly with different designs. The mode of operating the controller will depend on circumstances, that shown in Figs. 3 and 5 being by means of a chain and chain wheel, the controller and resistances being mounted on the crane girders. This method is useful for small cranes, but where a cage is used the controller should be provided with a handle and a definite "notch" for each position of the controller. In the former case, a spring should be provided to bring the controller to the "off" position as soon as the chain is released. Definite notches are not required in this case, as the controller should return to the "off" position as soon as the crane-driver releases the chain.

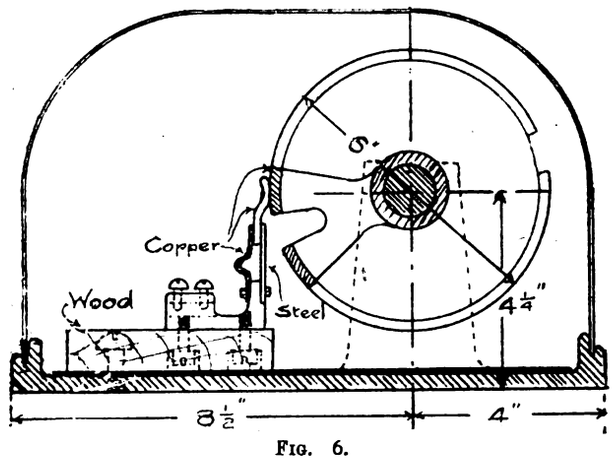

FIG. 6.

The resistances should be of the grid type, and the total resistance per phase should be that recommended by the manufacturer, in order for the motor to give the requisite starting torque. Generally, for a motor of this size a resistance of from about 1·6 to 2·0 ohms per phase will be sufficient. This refers to the resistance between points R_1 and R_8, while that between R_5 and R_8 may be one-third to one-half of this value. The resistance should be designed to carry the full-load rotor current of the motor, which may be obtained by multiplying the full-load stator current by the ratio of transformation, in this case two-thirds, the values, of course, being arranged to correspond to the connections of stator and rotor windings.

The value of the resistance to be inserted in each phase of the rotor for the motor to develop a given starting

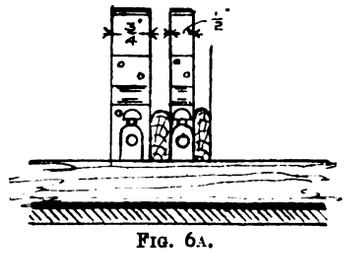

FIG. 6A.

torque with a given starting current may be ascertained by applying the "circle diagram."*—A. D.

Answer to No. 710 (*awarded* 7*s.* 6*d.*).—The motor in question has presumably a "wound" rotor fitted with three slip-rings, and has a ratio of total rotor turns to total stator turns of 2 : 3. Both windings will probably be star connected. Assuming a full-load power factor of ·85, and a full-load efficiency of ·85, the full-load stator current per line (or phase) will be $\frac{6 \times 746}{\sqrt{3} \times \cdot 85 \times \cdot 85 \times 100} = 36$ amperes, and the rotor current per line will be a little less than $36 \times \frac{3}{2} = 54$ amperes, say 52 amperes. Assuming, further, that the slip of the motor at full load is about 5 per cent., the C^2R loss in each rotor phase at full load will be about

$$\frac{6 \times 746}{3} \times \frac{5}{100} = 75 \text{ watts},$$

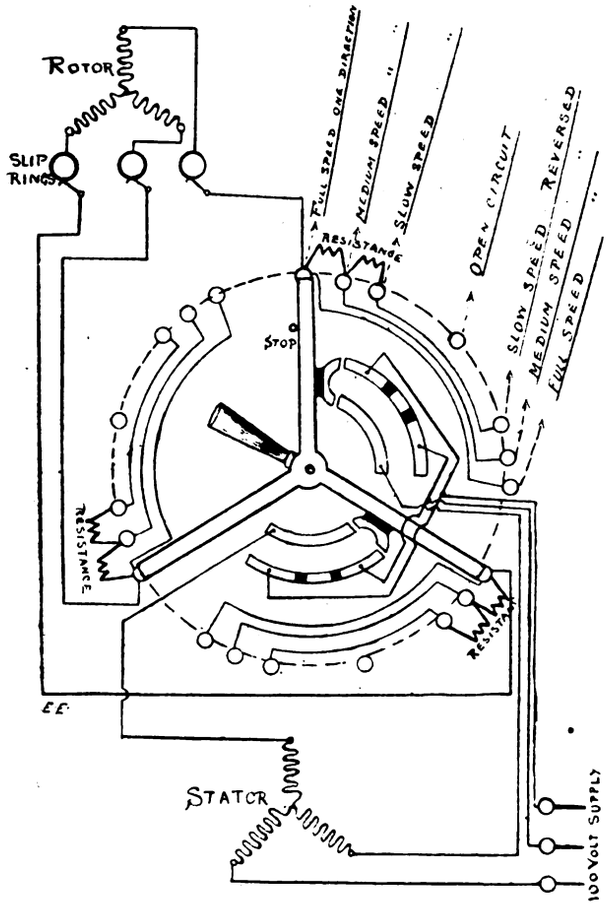
and the resistance of each rotor phase will be $\frac{75}{(52)^2}$ = ·0275 ohm.

* A very full and practical treatment of the application of the "circle diagram" is given by Mr. H. M. Hobart in his work on "Electric Motors: Their Theory and Construction."

Digitized by Google

As at least the normal full-load torque will be required at starting, the starting resistance should be proportioned so as to pass about the normal full-load current (52 amperes) when all is in circuit, so that the starting resistance per phase should be made about $\cdot0275 \times \frac{100}{5} = \cdot55$ ohm, divided into three or four steps. The total losses in this resistance at full current will be $(52)^2 \times \cdot55 \times 3 = 4{,}500$ watts for the three phases together. Allowing for a well-ventilated resistance frame, consisting of a number of wire spirals under a perforated cover, the number of watts per square inch of outer surface of frame could probably be safely allowed to reach a value of 6 at the maximum current, provided that the motor is running at full speed with all the resistance cut out for a fair proportion of the time. The outer dimensions of the frame should, therefore, be, roughly, 750 square inches, or, say, about 14in. high by 10in. wide by 10in. deep.

The controller switch might conveniently consist of a three-armed switch arranged on the top of the resistance frame. This switch must control the motor speed by inserting more or less of the resistance into the rotor



phases, finally short-circuiting the slip-rings for full speed, and at the same time must act as a reversing switch—*i.e.*, it must interchange two of the stator supply leads when the motor is on open circuit; then reinsert the whole resistance in the rotor phases, and gradually reduce this resistance until the rotor is short-circuited again and running at full speed in the reverse direction. The necessary connections are shown in Fig. 1.—Q.

Answer to No. 710 (*awarded* 5*s.*). — Supposing the efficiency of the motor is ·8, and the power factor $\cos \phi = \cdot82$, the primary absorbed current will be 40 amperes. Now, the secondary ampere-turns, the primary and the magnetising ampere-turns are represented by the three sides of a triangle having one angle equal to 90deg. $- \phi$. So, if the winding in stator and rotor are of the same kind, and if the magnetising current is 12 amperes, the full-load secondary current will be about 52 amperes (ratio of turns $\frac{2}{3}$), or, say, 55 amperes to allow for the secondary leakage. If 6 per cent. of the output is lost in the rotor winding (or say 270 watts), the resistance of one phase of the rotor is

$$R = \frac{270}{3 \times 57^2} = \cdot03 \text{ ohm.}$$

Supposing, now, we start the motor with the full-load primary current, the secondary starting current will be 55 amperes, and the starting voltage $\frac{100}{\sqrt{3}} \times \frac{2}{3} 0{\cdot}95 = 36$ volts (·95 is to allow for the leakage). The resistance, then, at starting must be $\frac{36}{55} = \cdot65$ ohm per phase. Suppose the controller has five steps per phase, or six studs, we must now divide the ·65 ohm in five parts. If we put the condition that the variation of the current, when the handle is moved from one to the next stud, is equal for all the studs and in the same time a minimum, we get the following formula :

$$\frac{i}{i'} = \sqrt[5]{\frac{36}{55 \times \cdot03}} = \sqrt[5]{21\cdot7} = 1{\cdot}85$$

36 = voltage at starting ;
55 = current at starting ;
·03 = resistance per phase ;
i and i' are the maximum and the minimum currents flowing in the rotor phase when passing from one to another stud.

The resistances in the five steps will be given by :

$$r_1 = \left(\frac{i}{i'} - 1\right) R = \cdot85 \times \cdot03 = \cdot025 \text{ ohm.}$$

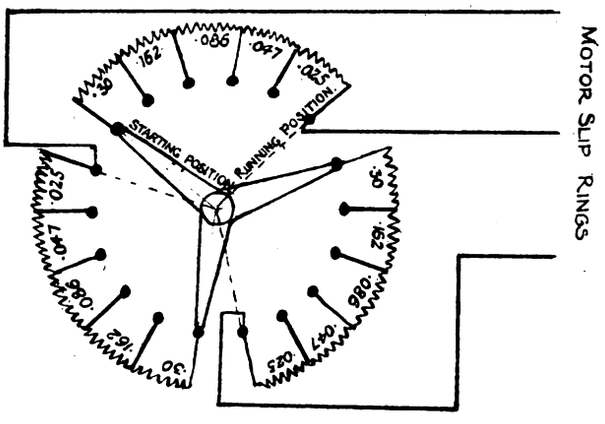
$$r_2 = \frac{i}{i'} \cdot r_1 = 1{\cdot}85 \times \cdot025 = \cdot047 \text{ ohm.}$$

$$r_3 = \frac{i}{i'} \cdot r_2 = 1{\cdot}85 \times \cdot047 = \cdot086 \text{ ohm.}$$

$$r_4 = \frac{i}{i'} \cdot r_3 = 1{\cdot}85 \times \cdot086 = \cdot162 \text{ ohm.}$$

$$r_5 = \frac{i}{i'} \cdot r_4 = 1{\cdot}85 \times \cdot162 = \cdot300 \text{ ohm.}$$

As verification it must be : $r_1 + r_2 + r_3 + r_4 + r_5 + R = \cdot65$. The torque at starting is proportional to the loss in the



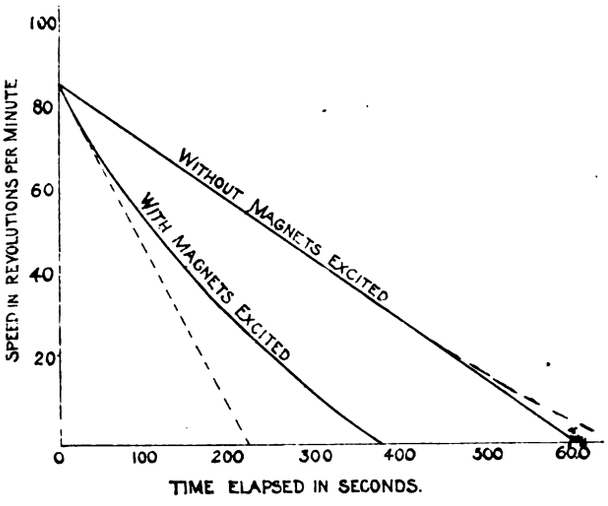
rotor copper : $3 \times 55^2 \times \cdot65 = 5{,}900$ watts. It is then about 30 per cent. more than the full-load torque. The diagram of connections is plain enough to be understood without an explanation. If we allow a density of 4,500 amperes per square inch we must use about six steps of Eureka wire, which can be easily put in an open box of 10in. by 10in. by 8in. These dimensions are quite sufficient for allowing the good ventilation necessary in a controller for lift motor.—N.

Question No. 711.—Give a clear description and example of a method of ascertaining core loss on a direct-current machine by observing the time taken to shut down from its normal speed with field on; secondly, with field off. Given the weights off the moving parts.

Answer to No. 711 (*awarded* 10*s.* 0*d.*).—The principle which underlies this method of determining the running losses—that is, the losses which occur all the while the machine is being used — is that when the machine is running at normal speed energy is stored up, and if all external sources of energy are cut off, this energy is gradually dissipated in overcoming the various forces which resist rotation. With an ordinary

Digitized by Google

flywheel, these forces consist only of bearing friction and wind resistance, but in the case of an armature revolving under excitation, there are also the magnetic forces set up by eddy currents and hysteresis to resist the rotation. To make the experiment, the machine is run up to speed, and then allowed to run free by taking out the clutch or by cutting off supply of current from both armature and field. As machine slows down readings are taken of the speed in revolutions per minute at the end of known intervals of time. The experiment is then repeated, but this time with the field magnets excited, a similar set of readings being taken. Curves are then plotted, as shown in example,



connecting revolutions per minute and time elapsed in seconds since machine was at its normal speed. The first curve is, it will be found, a practically straight line, while the other starts with a steeper slope, which gradually decreases in value until when the position of rest has been reached, the slope is the same as that of the first curve. Now, as the curves are plotted between revolutions per per minute and time in seconds, the "slope" will give the retardation of the machine in revolutions per minute per second, or multiplying the result by $\frac{2\pi}{60}$, we shall have the angular retardation in radians per second per second. We then apply the formula,

$$\text{Retarding torque} = \frac{\text{moment of inertia}}{32{\cdot}2} \times \text{ang. retardation},$$

and thereby knowing the retarding torque at the particular speed dealt with, we may calculate the watts lost from the well-known rule

$$\frac{T \times 2\pi n}{33{,}000} \times 746 = \text{watts}.$$

In the example, which is of a 450-kw. slow-speed traction generator, the full speed is 85 revolutions per minute, and it took 610 seconds to slow down. Therefore, angular retardation

$$= \frac{85 \times 6{\cdot}25}{60 \times 610} = 0{\cdot}0146 \text{ radian per second per second.}$$

In second curve the tangent at 85 revolutions per minute is A B; therefore, machine starts slowing down at the rate of

$$\frac{85 \times 6{\cdot}28}{60 \times 222} = 0{\cdot}0402 \text{ radian per second per second.}$$

The moment of inertia of the machine has been estimated to be 78,000 (ft.)^2 lb. units.

$\therefore$ Retarding torque in first case $= \frac{78{,}000 \times 0{\cdot}0146}{32{\cdot}2}$, and in second case $= \frac{78{,}000 \times 0{\cdot}0402}{32{\cdot}2}$.

The difference in the torque in two cases is due to iron losses. Therefore, torque due to iron losses

$$= \frac{78{,}000 \times 0{\cdot}0256}{32{\cdot}2}.$$

$$\therefore \text{Iron loss in watts} = \frac{78{,}000 \times 0{\cdot}0256 \times 2\pi \times 85 \times 746}{33{,}000 \times 32{\cdot}2}$$
$$= 7{,}650.$$

Similarly, friction loss at this speed is 4,360 watts.

Some writers on this subject have shown how the eddy-current losses and hysteresis losses may be separated from one another by this method. It will have been noticed that the second curve obtained had not a constant slope all along. This is because the retarding torque due to iron losses is, unlike that due to the friction losses, dependent on the speed. In fact, the hysteresis torque is directly proportional to the speed and the eddy-current loss is proportional to the square of the speed. The expression for the retarding torque in the second case is, therefore, of the form $A + B\,n + C\,n^2$, where n is the speed in revolutions per minute and A, B, and C are unknown constants. It is, therefore, claimed that by taking three points on the curve and proceeding in each case as before, we may solve the equations for A, B, and C, and thus separate the friction, hysteresis, and eddy-current components of the losses. This theory may be applicable in cases where the readings may be taken with extreme accuracy, but for the ordinary cases, owing both to irregularities in the experiment and to difficulty of drawing tangents correctly, it is not practical. Especially is the case with direct-current machines, where the eddy-current losses are generally small compared with the hysteresis loss.

A few remarks must be made on the estimation of I, the moment of inertia. In direct-current machines it is a matter of extreme difficulty to calculate this quantity directly, although in the case of magnet wheels of alternators it may be approximately arrived at by rules given in all treatises on applied mechanics. An experimental method is as follows: The machine is brought up to speed and the number of revolutions made before it comes to rest is noted. A suitable flywheel, whose I is easily calculated, is then attached to the shaft and the process is again repeated, no excitation being on the machine in either case.

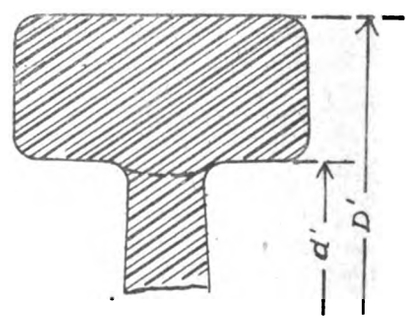
Let I_0 = known I of flywheel;
I_1 = unknown I of dynamo;
n_1 = revolutions made before coming to rest in first case; and
n_2 = revolutions made before coming to rest in second case.

Then $$I_1 = I_0 \left(\frac{n_1}{n_2 - n_1}\right).$$

A very neat expression for the I of flywheel indicated in sketch is

$$\left(\text{Weight of rim (lb.)} + \frac{\text{weight of spokes (lb.)}}{4}\right)\left(\frac{D^2 + d^2}{16}\right)$$

when the diameters are taken in feet.



Finally, in making the experiments as constant conditions must be obtained as possible, the machine being run for some considerable time to ensure that the friction is constant. In the case where the machine is excited, the speed may be accurately taken by reading a voltmeter applied to the terminals, and if the test is one being continually made, a recording voltmeter with a quick-moving drum may be used.—X. Y. Z.

[Other replies to Question No. 711 will be given in our next issue.—Ed. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS

721. An ejector condenser coupled close to the exhaust range and about 2ft. below, supplied with water from a centrifugal pump at a pressure of over 20lb. per square inch, will not, either in a vertical or horizontal position, give more than 20in. of vacuum. Explain the reason for this.—E. L.

ANSWERS.

Question No. 711.—Give a clear description and example of a method of ascertaining core loss on a direct-current machine by observing the time taken to shut down from its normal speed with field on; secondly, with field off. Given the weights off the moving parts.

Answer to No. 711 (*awarded* 10*s.*).—The following method is only applicable to machines with armatures of such

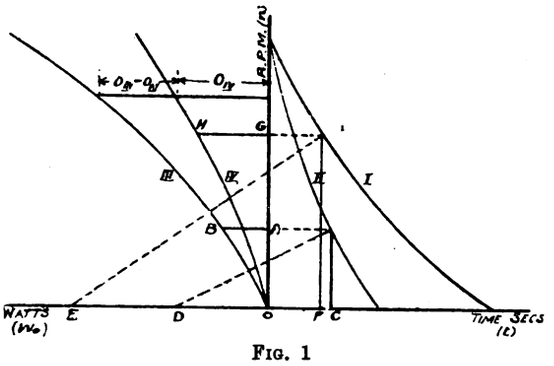

FIG. 1

weight that the time occupied in shutting down with excited field is at least 20 seconds. If the machine be running as a motor, and both supply to the armature and field current be suddenly cut off, then the energy stored in the rotating armature will be consumed solely in overcoming the mechanical losses; the speed will gradually decrease, and the armature will finally come to rest. If in cutting off the armature current the field be left on, additional hysteresis and eddy-current losses will come into play; the time occupied in shutting down will now be of shorter duration. The theoretical side of the question being somewhat involved, it will perhaps be best to treat the mathematics of the case first and then proceed to the actual test. An element of mass a moving at a velocity v per second possesses an energy of

$$E = \frac{a\,v^2}{2}.$$

For a complete body—viz., the armature—

$$E = \Sigma\,\frac{a\,v^2}{2}.$$

If a body revolves around an axis, then an element of mass a of the same at a distance y from the centre has a velocity

$$v = y \times S, \text{ where } S = \frac{2\,\pi \times n}{60} \ (n \text{ standing for R.P.M.}).$$

$$\therefore \Sigma\,\frac{a\,v^2}{2} = \Sigma\,\frac{a\,y^2\,S^2}{2} = \frac{S^2}{2} \times \Sigma\,(a\,y^2).$$

The expression $\Sigma\,(a\,y^2) = I$ is the moment of inertia.

$$\therefore E = \frac{S^2}{2} \times I.$$

In Fig. 1, Curve I. represents the relation between time and speed with field off. Curve II. gives the same relation but with the field excited. For any instant, t, the consumption of energy per second is given by

$$-\frac{d\,E}{dt}\,\frac{d\left(\frac{S^2}{2} \times I\right)}{dt} = \frac{I}{2} \cdot \frac{d\,S^2}{dt} = I \times S\,\frac{d\,S}{dt}.$$

$$\therefore S = \frac{2\,\pi \times n}{60} = \frac{\pi\,n}{30}.$$

$$\therefore -\frac{d\,E}{dt} = I\,\frac{\pi\,n}{30} \cdot \frac{\pi}{30} \cdot \frac{dn}{dt} = I\left(\frac{\pi}{30}\right)^2 n\,\frac{dn}{dt}.$$

$I\left(\frac{\pi}{30}\right)^2$ is a constant value for any particular machine, and represents the subnormal of the n/t curve. $\therefore$ substituting K for $I\left(\frac{\pi}{30}\right)^2$, we have

$$-\frac{d\,E}{dt} = K \times n\,\frac{dn}{dt} \quad \ldots \quad (1)$$

i.e., the watt loss $-\frac{d\,E}{dt}$ per second is proportional to the sub-normal of the corresponding n/t curve. The constant K once known, the loss curve may be deducted from the n/t curve. The value K, however, is awkward to calculate on account of the difficulty of finding the factor I It is possible to ascertain the moment of inertia, I, without the use of higher mathematics by means of a tabular method, as set forth in Alexander and Thompson's "Applied Mechanics," or even by graphical solution (see *Practical Engineer*, Dec. 6, 1895).

A much more direct method of finding K exists, which, furthermore, does not depend on any particulars as to weight or section of the revolving parts being given. To this end plot Curve III. for the excitation at which the losses are to be determined, placing values for speed, n, against total no-load losses, W_0 (see Fig. 1). Then find Curve II. for the same exciting current, and, finally, Curve I. with field off. The value K may be got from Curves II. and III. For by equation (1) watt loss, W_0, of Curve III. for a certain speed, n, is equal to K × sub-normal for the corresponding n on Curve II. Referring to Fig. 1

$$B\,A = K \times D\,C. \quad \therefore K = \frac{B\,A}{D\,C}.$$

Once K is found, the friction loss (Curve IV.) may be deducted from Curve I. For instance, the ordinate H G is determined by the relation

$$H\,G = K \times E\,F.$$

Finally, the difference of any two corresponding ordinates ($O_{III} - O_{IV}$ in Fig. 1) will give the required ordinate of the curve of no-load core losses. It may not be out of place to specially call attention to the fact that the result merely represents the *no-load* core losses. Under load the distribution of the flux is altogether a different one, which necessarily affects the losses very materially.

From the wording of the question one would take it that "E. S. C." merely wishes to ascertain the aggregate core losses. It is but a slight matter to now separate the hysteresis and eddy-current losses, and as this process is

Digitized by Google

quite a well-known one it hardly seems necessary to dwell upon the question. Such being the theoretical aspect of the problem, the actual mode of carrying out the test will be somewhat as follows: Connect up as per Fig. 2. Run machine light with the field separately excited, and observe that the exciting current be kept at a constant value throughout the test. The machine had preferably be

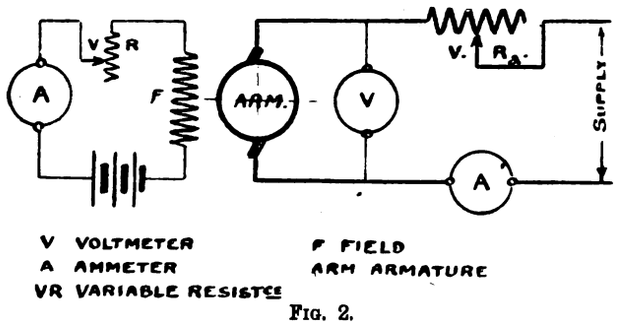

FIG. 2.

had running for some time previous to taking readings to allow the temperature to rise to its normal value. First, determine Curve III., starting at full speed. Take simultaneous readings of voltage and current in armature circuit and speed of machine. Gradually insert resistance, V R_a, and take readings afresh. Plot results as shown in Fig. 3, taking values for n vertically and armature volts × armature current horizontally. Then proceed to take n/t Curves I. and II., again starting from full speed. The speed should be taken by means of a tachometer at intervals

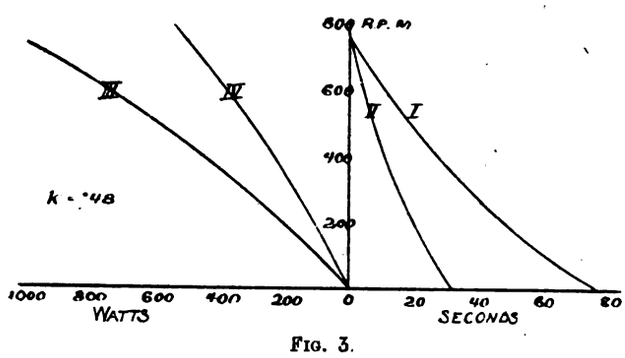

FIG. 3.

of five seconds. The best plan is to get an assistant to mark the time intervals by periodically striking a bell.

All the required readings being now taken, the remainder is done by graphic solution. Determine constant K, which is equal to any ordinate B A of Curve III. divided by the

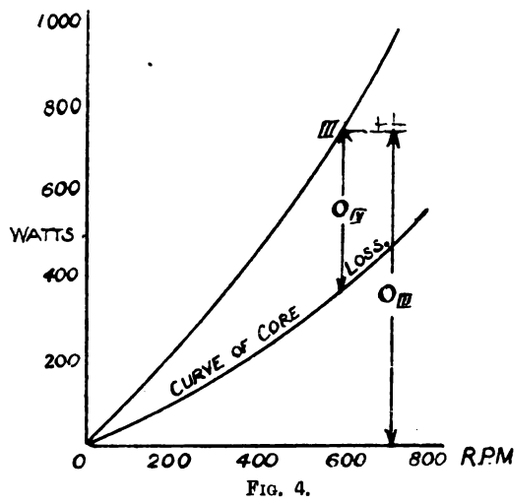

FIG. 4.

corresponding sub-normal D C of the n/t Curve II. As all values got from various points in this manner should yield the same result, the mean value should be adopted. To find any ordinate H G of the friction loss, Curve IV., use the relation H G = K × E F.

For the final result, plot Curve III. as per Fig. 4, and fix several points for the no-load loss curve by deducting any ordinate O_{IV} of the friction loss curve from the corresponding ordinate O_{III}, as per diagram. *Note*.—Figs. 3 and 4 show the actual results obtained on a 15-h.p. machine by Witting Bros., Limited.—R. E. C. IHLEE.

Answer to No. 711 (*awarded* 7*s.* 6*d.*).—To determine the core loss in a machine by the method referred to in the question, a knowledge of the "moment of inertia" of the moving parts is essential. This cannot be calculated unless the weights of the moving parts and their respective radii of gyration are known, but it can be found experimentally by various methods, a convenient one being as follows: The machine is run as a separately excited motor, and the power supplied to the armature accurately measured. Subtracting from this the energy lost in heating the armature coils, we obtain the power actually expended in driving the motor against the resisting forces.

Then if T = retarding torque in C.G.S. units acting on the armature;
w = angular velocity at any instant;
I = moment of inertia of revolving parts;
W = power in watts actually expended in driving motor;

we have $$T = I\frac{dw}{dt} = \frac{-W}{w} \times 10^7.$$

In the above equation both I and $\frac{dw}{dt}$ are unknown, but $\frac{dw}{dt}$ can be determined graphically from a curve connecting w and t, and its value inserted in the above

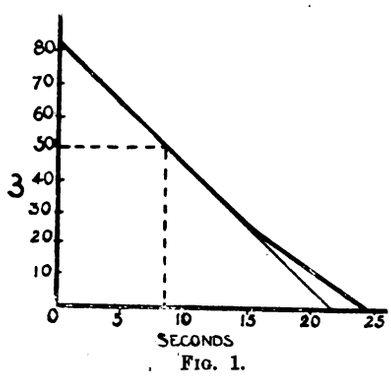

FIG. 1.

formula, thus allowing I to be calculated. The data for plotting this curve is obtained by suddenly cutting off the power from the machine when running on open circuit at any desired speed, and as the armature slows down observing the speed by means of a tachometer at known intervals of time. Fig. 1 represents a curve plotted from readings obtained in this manner. It will be seen that the tangent to the curve is indistinguishable from it for a considerable distance, and can therefore be drawn with great accuracy. For $w = 50$

$$\frac{dw}{dt} = \frac{81}{22} = 3{\cdot}68.$$

Now, consider the motor to be fully excited, and to be running on open circuit at the normal speed. On cutting off the power to the armature, the machine will gradually come to rest under a retarding torque due to the losses on the machine. At any speed, w, this retarding torque has a value

$$T = -I\frac{dw}{dt},$$

and the corresponding power $= Tw = -Iw\frac{dw}{dt} \times 10^{-7}$ watts (the letters having the same meaning as given above). Since I is known and $\frac{dw}{dt}$ can be determined as shown above, the power at any speed can be calculated. This power at any speed, w, is obviously equivalent to the energy dissipated by bearing, brush, and air friction, hysteresis, and eddy currents at that particular speed. If, therefore, we calculate values of the power for various speeds, a curve can be plotted showing how the energy dissipated varies with the speed. Repeat the above experiment, but with the fields cut out, and plot values of

Digitized by Google

power and speed, obtained as above, on the same sheet. The difference between the ordinates of the two curves, at any speed, gives the core loss for that speed and excitation (see Fig. 2). To separate the hysteresis and eddy-current losses, plot a curve having values of "energy lost in

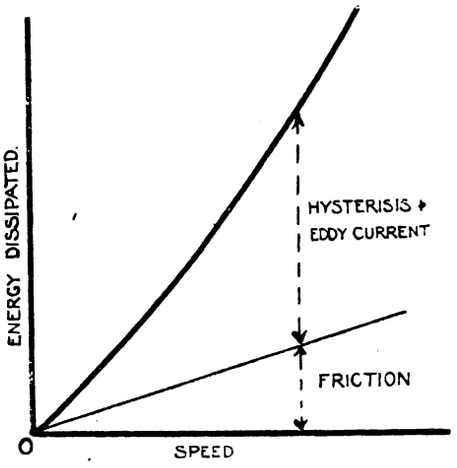

FIG. 2.

hysteresis and eddy currents" ÷ speed for ordinates, and speed for abscissæ. Since the hysteresis loss varies as the speed, while the eddy-current loss varies as the square of the speed, it will be seen that a line drawn parallel to the

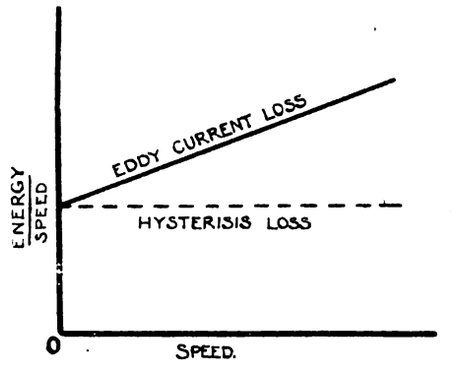

FIG. 3.

abscissa through the point in which the curve cuts the ordinate will separate them (Fig. 3).—C. L. S.

Question No. 712.—Explain the necessity of reactance on the alternate-current side of a rotary converter.

Answer to No. 712 (*awarded* 7*s.* 6*d.*).—One of the many problems connected with the running of rotary converters is that of pressure regulation. The ratio of the E.M.F. between the commutator brushes and that between any two slip-rings is practically constant for any machine, and is independent of the field. It follows, therefore, that to obtain any alteration in the voltage across the brushes a corresponding alteration in the voltage applied to the slip-rings must be made. This variation of the voltage on the alternating-current side can be effected by hand or automatically. In the former case either an "induction regulator" can be used or the ratio of transformation varied (assuming that step-down transformers are used, as is generally the case), while in the latter case the regulation is effected automatically by compounding the rotary, and providing a certain amount of self-induction between the secondary of the transformer and the slip-rings, if not already existing, by inserting small reactance coils in the various leads.

The following is an explanation of its working: Assume the rotary to be working on a fixed load, and that the current is in phase with the volts. On increasing the excitation it will be found that the current through the armature will have increased, and is now leading, while reducing the excitation will also cause the current to increase, but it will now be lagging. If we take readings of the armature current for various excitations, we can plot a curve which will have the shape shown in Fig. 1. At the bottom of the curve, A, the armature current, will be a minimum, and is practically in phase with the volts; any variation in the exciting current now causing the armature current to increase, and to lead or lag, depending whether the excitation is increased or reduced.

Now, in any circuit having inductance a leading or lagging current will cause a rise or fall in voltage respectively. This will readily be seen by an inspection of Fig. 2.

Let O C represent the current taken by the rotary per phase; O L will then represent the E M.F. per phase

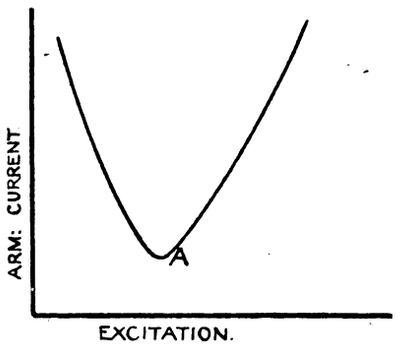

FIG. 1.

required to overcome the back E.M.F. due to self-induction and that required to drive the current through the resistance of the circuit. O E represents the E.M.F. induced in the secondary of the transformer, which may be taken as constant. It will be seen that when the current lags (by the angle D) behind the induced E.M.F. in the secondary, E L will represent the back E.M.F. of the rotary, which, neglecting the drop due to resistance and self-induction,

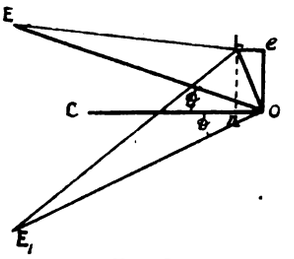

FIG. 2.

may be taken as the E M.F. at the slip-rings. Obviously E L is less than O E Similarly, when the current is leading by the angle D, E_1 L represents the E.M.F. at slip-rings, and is evidently greater than O E_1.

Considering the rotary converter, it will be now obvious that if there is sufficient reactance on the alternating-current side, and the rotary is compounded, the E M.F. across the slip-rings, and, consequently, that across the brushes, will increase as the load increases. In fact, if the shunt excitation is so proportioned that at no load the rotary takes a lagging current about 30 per cent. of the full-load current, due both to under-excitation and reactance, the rotary can be made to regulate perfectly automatically from no load to about 10 per cent. overload.—C. L. S.

Answer to No. 712 (*awarded* 7*s.* 6*d.*).—Reactance is put in series with the alternating-current side of a rotary converter in order to keep the direct-current voltage constant at all loads, or even to increase it as the load increases. The voltage of the D.C. side of a rotary converter is quite independent of the field strength, so that compounding in the ordinary way is out of the question.

At the same time, a rotary converter, considered from the alternating side, behaves exactly like a synchronous alternating motor, and instead of having a fixed input current for each load, the input current varies according to the excitation.

If the machine is excited to give too great an internal voltage to correspond with the supply voltage, a leading current (lagging with respect to the internal back voltage) is drawn from the supply and weakens the field to the required extent by armature reaction, whilst if excited to give too small an internal back voltage, a lagging current

Digitized by Google

(leading with respect to the internal back voltage) is taken and serves to strengthen the field.

If, therefore, a rotary converter is fitted with a compound field winding on the D.C. side and with a definite amount of resistance, either in the form of cables or of separate choking coils, on the A.C. side, the proportion of shunt and series winding can be so chosen that the current at light load is a lagging one (shunt made too weak for unity power factor), causing a large drop in the reactance and so lowering the A.C. terminal volts, whilst at full load the current could be made a leading one (series winding made too strong) which, in combination with the reactance, causes an actual rise in the alternating terminal volts above the supply volts. Thus, if in Fig. 1,

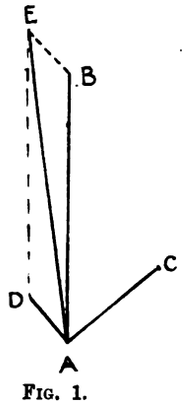

FIG. 1.

A B represents the alternating-current terminal volts at light load, and A C the lagging input current at light load, the drop in the reactance may be represented by the line A D at right angles to the current A C, and the line A E (which is the vectorial sum of the two voltages, A B and A D) represents the supply voltage.

At full load, if the supply current is a leading one, it will be represented by such a line as A C (Fig. 2), and the voltage across the reactance by the line A D (longer than A D in Fig. 1 in the ratio of full-load current : light-load current) at right angles to A C. The supply voltage required in order to obtain a terminal voltage, A B, will again be represented by the line A E, but this line will be

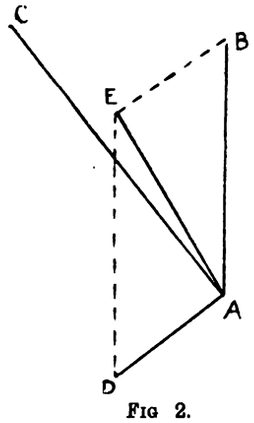

FIG 2.

seen to be shorter in Fig. 2 than in Fig. 1—*i.e.*, a smaller supply voltage is required at full load than at light load for the same terminal voltage, A B, or, in other words, with a constant supply voltage the terminal voltage will be higher at full load than at light load.

There is, however, an objection to this method of voltage regulation, in the fact that the power factor is unity only at one particular load (usually about half load), whilst at full load it may fall to ·9 or less with a leading current, and at light load to ·8 or less with a lagging current. This causes a greater line loss, greater heating in the rotary converter itself through $C^2 R$ loss, and unsteadiness in the running of other apparatus working off the same A.C. supply, through the wide changes of the power factor of the circuit.

Further, in order to get any considerable compounding effect the converter field strength has to be varied over a wide range between no load and full load by means of the compound winding, and this may in some cases give trouble through sparking and through instability of field.—Q.

Answer to No. 712 (*awarded* 5*s.*).—In the first place, it may be remarked that reactance is not an absolute necessity for the operation of rotary converters. In fact, in one London installation known to the writer the trouble experienced in running the rotaries was diminished when the reactance coils specially provided by the manufacturers were cut out. In some cases, however, these coils are used with advantage, and for the two following reasons:

1. The voltage on the D.C. side is made to rise with the load if the A.C. flows through a reactance, and *if it is leading* the applied E.M.F. This is shown in the accompanying vector (Fig. 1). O E is the voltage from the line, and O C represents the leading current. Then O E corresponds to the reactance voltage caused by this current, and this added vectorially to the back E.M.F. of A.C. side of rotary must equal O E (ohmic resistance being neglected). There-

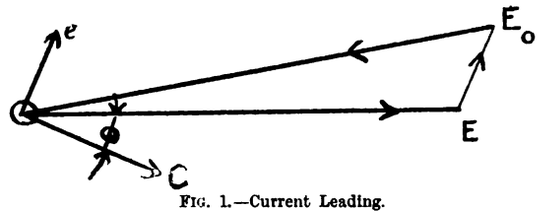

FIG. 1.—Current Leading.

fore, having regard to direction of arrows, we have O E_o as the voltage to be generated by rotary. This larger voltage is also generated on the D.C. side, for the ratio $\frac{\text{A.C. voltage}}{\text{D.C. voltage}}$ is a number depending only on the number of phases, and therefore constant for any one machine. So that when a leading current flows, the D.C. voltage is higher than at no load.

2. The second reason why reactance is put in series with the rotary is to minimise hunting by damping the surging currents, which flow only when the rotary hunts. The surging currents are of two kinds—viz: (*a*) those due to the swing of the machine about the position of absolute synchronism; and (*b*) those due to the different machines taking more or less current from the mains, because during the hunting they take more or less of the D.C. load.

For (*a*) the reactance coils are not of much use, as the period of the fluctuations of the current is large compared with the period of supply, it being of the order of seconds rather than of the order of hundredths of a second. For (*b*) the reactance coils are only of advantage when the current taken from the machine is lagging, for, taking the

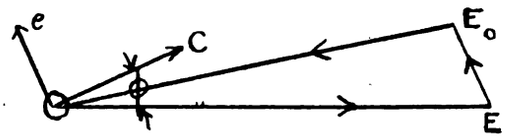

FIG. 2.—Current Lagging.

case of that rotary which at any instant is taking most current, the drop across the reactance will cause the required back voltage of rotary to be smaller (Fig. 2), and therefore the D.C. voltage will be smaller, and the machine will therefore take less load. If, on the other hand, the current supplied is leading, as we have already seen, the rotary taking most current will have the highest D.C. voltage, and will thus take more of the load, require more current from A.C. side, and so tend to increase the hunting.

The conclusion is, therefore, that if rotaries are inclined to hunt *among themselves*, the reactance coils are only of use if the current supplied is made *to lag*, and in this case they are not useful for self-regulation. If, on the other hand, the rotaries run well together, the coils may be used for regulating purposes by causing the current *to lead*.—Z. Y. X.

QUESTIONS.

722. Describe the best methods of plating carbon brushes with copper or nickel, having regard to the fact that carbon is porous and absorbs the electrolyte.—W. G.

723. The poles of a shunt-wound direct-current machine (bipolar) are found to be reversed after dealing with a heavy short, the current probably amounting to 350 amperes, the normal full load of the machine being 180 amperes. Can any reason be given for this?—C. W. S.

724. A three-phase high-pressure alternator has too large a pressure drop from no load to full load. What means are there of remedying this?—V.

ANSWERS.

Question No. 713.—Describe what you consider the best method of truing up large commutators, say from 5ft. diameter upwards.

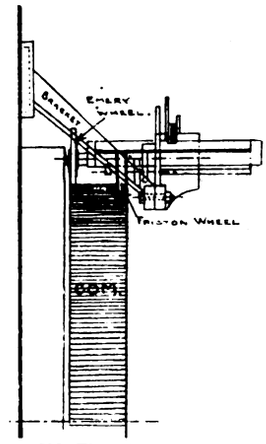
Best Answer to No. 713 (*awarded* 10*s.*).—Before attempting to "true up" a commutator by turning and grinding, it is as well to be sure that it really requires doing up. A well-built commutator, with the right kind of mica insulation, should not, if given proper attention, require truing up very often. Daily attention given to brushes and gear goes a long way towards keeping a commutator in good order without having to put a tool on it every few months.

There are several methods of truing up accumulators, two only of which need be considered here: (1) by ordinary tool held in a simple slide-rest; (2) by emery wheel mounted on a special slide-rest.

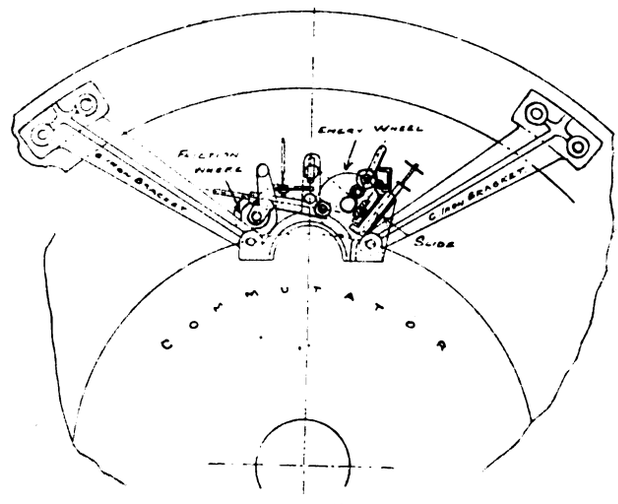
The first method possesses the advantage of being cheap in first cost, but against this it requires considerable skill in manipulating, as unless the operator has a good working knowledge of turning, he is pretty sure to make a mess of the job. Even after the finishing cut is taken it is necessary to run a file over the commutator, and here again a skilled operator is required, as the art of filing is not learned in five minutes. One often meets with men holding comfortable berths in large central stations who claim to have served their time in a good shop and know everything from the moulding shop right through to the test-house, yet when it becomes necessary—as it sometimes does—to tackle a small job at the vice, what a mess they make of it, and usually after a lot of tall talk to the fitter—"seems to be a bit skilled," "out of practice," etc.—the man in the blue slop eventually finishes the job. It is amusing to note the care the big-salaried one bestows on his highly coloured left thumb and the blister on his right palm for some days after his little attempt to air off his shop training. A small toolholder to take ½in. tool steel of V section is suitable for commutator work, as a breakage of the tool does not necessitate heating and drawing out, as is the case with an ordinary tool, grinding only being required. The correct cutting angle of tool for turning copper is 84deg., angle of relief = 7deg. Best speed for turning copper is from 90ft. to 120ft. per minute.

Method No. 2 is perhaps the best all round. Of late years the commutator grinding machine has found much favour with central-station engineers, many hundreds of these machines now being in use. There are two types of this machine, these being made in a variety of designs to suit different sizes of commutators: (1) driven direct from the commutator to be trued up; (2) driven from a separate source, usually a small motor.

Figs. 1 and 2 belong to type (1), and show two different methods of attachment on machines having commutators 4ft. to 8ft. diameter. This grinder—made by the Phillips Machine Syndicate, of Eastcheap, London, E.C.—can be fixed up in 15 minutes, and the commutator trued up in less than half the time ordinarily required, and in the most



Side Elevation.



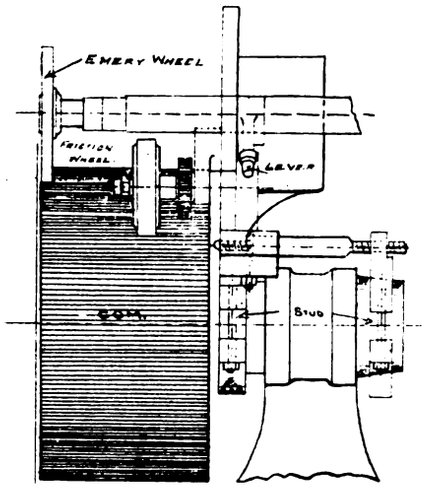
Front Elevation.

FIG. 1

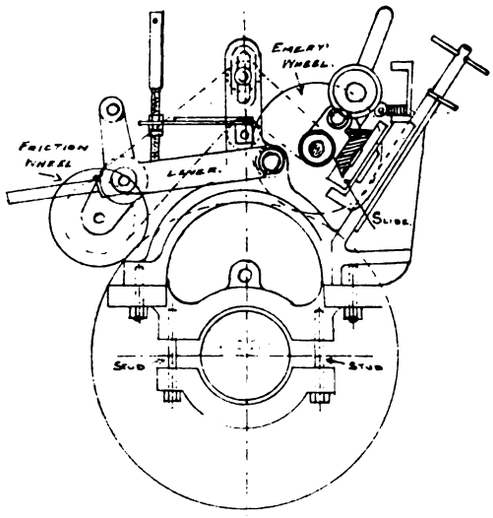
perfect manner. The grinding spindle is driven direct by means of a specially prepared rubber friction wheel running on the commutator, so that no motor is required to drive it. The spindle is carried in a strong slide and is absolutely rigid. The bearings are of great length, and the spindle and drum are evenly balanced, so as to run at the necessary high speed without causing vibration. The grinding spindle when working moves to and fro across the face of the commutator, and is automatically reversed at each end, and is so constructed that stops can be set as in a planing machine, grinding the surface right up to the connecting wires and back to the edge. The only thing required of the attendant is to watch the feed. The grinding wheel should, of course, run in the opposite direction to the commutator. In

Digitized by Google

type (2) the machine is of somewhat simpler design, owing to the absence of the direct driving gear. The writer has used this machine on commutators up to 3ft. diameter with hand-controlled feed, but experienced a difficulty in getting a satisfactory belt drive. When truing up commutators, it is a good plan to fix a piece of stiff paper over the ends of



Side Elevation.



Front Elevation

FIG. 2.

the armature connections to prevent copper dust lodging between the windings.

A handy tool designed by the writer for cleaning commutators is shown in Fig. 3. It is made of well-seasoned deal, and built up in two pieces, the grain of the parts being at right angles to each other. It is best and cheapest in the long run to use emery or glass cloth, not paper.

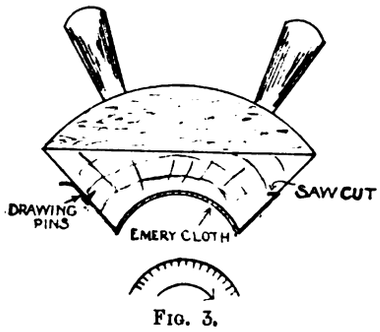


FIG. 3.

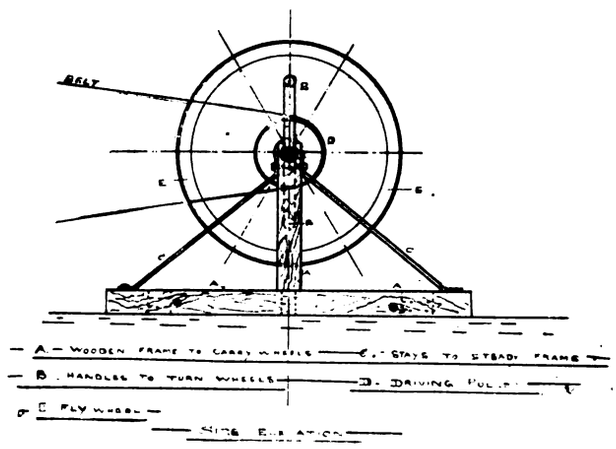
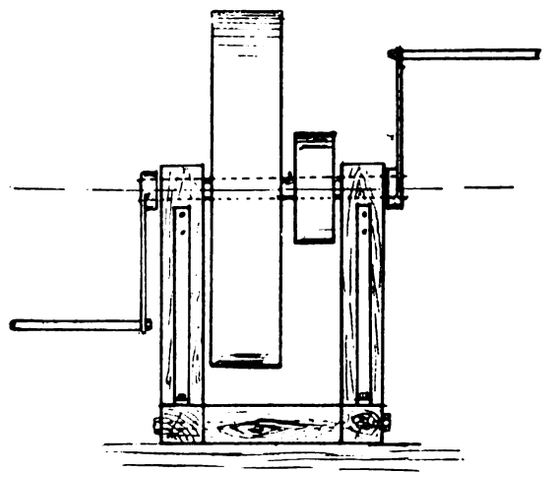
When using this tool, a little oil should be smeared along the front edge of the emery cloth, as this will prevent a lot of dust from rising and irritating the operator's eyes and nose. The correct way to use the tool is against the direction of rotation of the commutator, as indicated by the arrow. Where there are a number of commutators of different sizes it is, of course, necessary to have a separate block for each size. A commutator cleaner made by the Ediswan Company consists of a sheet of thin steel, which is curved to fit the commutator. By means of adjusting gear it can be adapted for use on different sizes of commutators. A sheet of emery or glass cloth is fixed to the under side of the cleaner, and suitable handles are provided for holding the tool to the face of the commutator.—S. L.

Answer to No. 713 (*awarded* 7*s.* 6*d*).—In truing up commutators two methods may be adopted—viz, grinding and turning—and as I consider turning makes the better job of it, I will speak chiefly upon that method. The first thing to be considered is the method of obtaining the necessary rotary motion of a proper speed, and it will be found that about 30ft. per minute is a good cutting speed, giving best results, but presuming that suitable driving gear is not to hand, then an improvised driving gear must be constructed. By referring to the accompanying sketches a method will be seen which has the advantage of being both inexpensive and efficient, and the writer has many times used the like for driving all kinds of machinery when





Front Elevation.

other motive power was unavailable. The flywheel in this case was the wheel from a semi-portable engine, and the pulley a wooden one with wrought-iron plates screwed on to take the shaft and keys. The frame should be made of good hard wood, and well bolted together and stayed. Having now got the driving gear fixed up, disconnect the brush gear and rockers, field leads, etc.; get the compound slide rest of a lathe, and fix the same up upon suitable timber framing secured to the framework of dynamo at such a height that the point of the tool is just a trifle *above* the centre of commutator, and wedged firmly so as to prevent vibration or chatter whilst the tool is cutting. Take fine cuts, and do not use oil or emery. The tool should be a simple diamond point, with the "point" slightly rounded and free from lip or cutting edge, as copper is queer stuff to work, and if there is much lip on the tool it will "dig in," and the last state of the commutator will be worse than the first. For the finishing cut the point of the tool may be slightly more rounded, and with care no trouble need be found

Digitized by Google

in making a first-class job. If it is desired to grind the commutator, an emery wheel may be fitted to the machine, with a friction pulley running on the periphery of the commutator, which gives the necessary rotary motion to the grinding wheel, or there are plenty of grinders on the market specially made for the job; but, as I said before, I consider the turning makes the better job, does not make such a mess, and there is not the danger of the copper dust getting into the armature nor the emery dust into the bearings.—BARON.

Answer to No. 713 (*awarded* 5*s.*).—There are generally two methods of truing up commutators: (1) by using a slide lathe rest, or (2) by using one of the emery grinders designed for such purposes. I have had to do with several grinders, but one that I am very familiar with is the Phillips Lightning grinder. It is designed to fit in the position taken up by the brush rocker on small machines, but for machines your size it is made to fit on the bolts that secure the pedestal on shaft bearing by means of a stand provided with grinder. When you have got your machine fixed you bring the rubber-faced wheel to bear on commutator, which drives the emery wheel by means of leather belt in the opposite way to which dynamo is running, and if used with a fair amount of judgment, and the instructions observed that are sent with the machine, you will find no difficulty making a first-class job of your *com.* The action of feeding your emery wheel along face of com. is entirely automatic or can be worked by hand. This grinding method is much more practicable than using the slide-rest and the ordinary V tools used for the purpose. After grinding use a sheet of emery cloth, preferably No. 0, and you have a com. in good condition without filing it, as is necessary after turning. Be sure to blow your machine out after job is finished.—S. H. LEE.

Answer to No. 713 (*awarded* 5*s.*).—The *best* method will depend considerably upon circumstances. If it is possible to rig up a slide-rest and run the machine at a slow speed, there is no more satisfactory method than turning up the commutator in position. The tool should be pointed, have little or no rake, and be placed slightly below the centre. By using a pointed tool there will be less chance of jarring; if the commutator is made true, it can easily be polished. Moreover, with such a shaped tool there will be less danger of small pieces of abraided metal short-circuiting the sections. Given a tool with little rake, and slightly below the centre, the liability to "run in" will be at a minimum. A smooth file will quickly give a good surface to the commutator. A small emery wheel, driven in opposite sense to that of the direction of rotation of the commutator, capable of being moved backwards and forwards across the face, makes a good job. If, however, there is much metal to be removed, it is a slow process. In any case before truing up, look round for any loose or badly worn sections; also any sections that may have risen above their normal positions. By slacking back rings, any such cases may be rectified, and if necessary, new sections inserted in place of any that are in a very bad condition. When there are only one or two "high" places, a few minutes with a rough file will save a considerable time in turning. With the dynamo as now made, commutators do not require to be turned up so often as was the common practice some fifteen or twenty years ago. Taking a case where neither slide-rest nor emery wheel is available, a good workman can still make a fair job of a bad commutator. First see that rings are tight and the sections in position. Rotate, and mark "high" places by means of piece of chalk held in the hand. These high places are now to be filed down with a rough file; mark again and so on. When got fairly true fill up whilst running. A pair of half-round polishing sticks and some emery cloth will soon make the commutator very presentable. The suggestion of emery cloth is quite contrary to the advice given in nearly all text-books; the general dictum of most writers on the subject is to use glass-paper. The writer, however, speaking after considerable experience, has never found glass-paper of much use for the purpose, and has invariably used emery cloth. There is rarely time to use glass-paper; emery cloth acts quicker and more satisfactorily.—M. M.

Question No. 714.—Give, with sketch, what you consider the best method for testing car axles; also the remedy for crystallisation, which has been found to take place just at the boss of wheel. All axles have been found broken at the same point, just inside the hub.

Best Answer to No. 714 (*awarded* 10*s.*).—To test the value of iron or steel for car axles, and the effect of strains similar to those imposed in service, Mr. Wohler, chief engineer of the Prussian State Railways, constructed machines for the purpose, by which the bars were exposed to vibrating actions and repeated strains within adjustable limits. For straining a cylindrical bar in the manner similar to that in which an axle is acted upon by the load it carries, the machine shown in Fig. 1 was employed. The bar was placed in bearing and caused to revolve at one end (corresponding to the journal of the axle), is loaded by a spring at a considerable distance, "overneck" giving a constant downward pull, by which action the bar is bent down to a fixed distance, and in its rotation the action of the spring caused it to bend in all directions round the circumference, by which means alternating strains of compression and tension are produced.

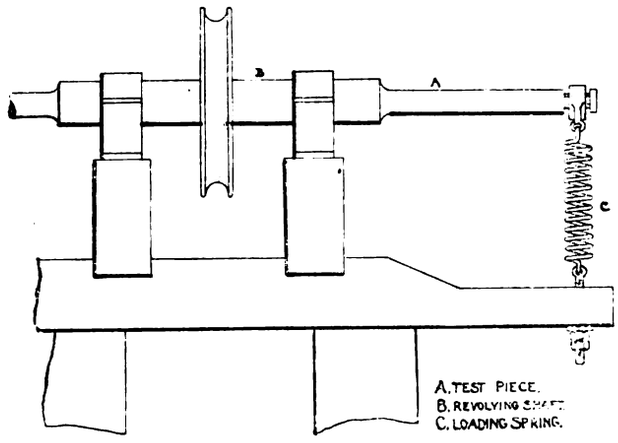


FIG. 1.

The following is extracted from a paper on "Steel Axles," read before the Western Railway Club, Chicago, in May last by Mr. J. L. Replogle, superintendent of the forge and axle department of the Cambria Steel Company: "We have seen broken axles around in various railroad shops, the examination of which leads us to the conclusion that failures were due to the fact that steel was too low in elasticity and tensile strength, steel of probably 30 or 35 per cent. carbon being used. The failures were due largely to what has been termed 'fatigue of metal,' and show a detail fracture, a gradual parting of the steel, extending toward the centre all round the piece, unquestionably caused by the imposed strains repeatedly approaching the low elastic strength of the soft steel. The substitution of a steel of higher carbon and elasticity would prevent failure of this kind." The observations of Dr. Chas. B. Dudley, the eminent chemist of the Pennsylvania Railroad Company, are interesting and pertinent to this subject, and we quote him: "It is obvious that the journal of a car axle gets alternating stresses—that is, the metal is subject to alternate tension and compression with each revolution, and that during the life of an axle these stresses are many thousand and perhaps million times repeated." The metal between the wheels is in like manner subjected at each revolution to the same alternating stresses. The effects of these repeated alternate bending stresses are almost too well known to need comment. A marked characteristic of the fractured surface of a piece of metal which has broken from this cause is that it never presents fibrous appearance in the fracture, but is more or less smooth, possibly due to the fractured parts rubbing against each other, and having the appearance of an old break. It commences where the maximum stress occurs on the surface of the section, and gradually works in from the surface until too small a part of the original area is left unbroken that a sudden shock or stress finishes the rupture. This breaking slowly, a little at a time, is called "detail fracture."

The experience of the Pennsylvania Railroad Company on car axles on this point may be interesting. Steel axles were first used on the railroad in 1875. The maximum

Digitized by Google

calculated fibre stress between the wheels was about 15,000lb. per inch, and the maximum fibre stress in the journal was about 6,700lb. per square inch. The steel of these axles was an acid, open-hearth steel, containing from ·22 to ·28 per cent. carbon and not over ·04 per cent. phosphorus, and with a tensile strength of about 65,000lb. per square inch, and an elongation in 2in. of over 25 per cent. So tough was this steel that one passenger-car axle was tested under the drop test with 67 blows without rupture. (Note.—The drop-testing machine has always been favoured by railway companies for proving rails and car axles. The apparatus is simple, consisting merely of a large anvil on which are supports for the beam to be tested, a pair of upright guides, and a falling weight that can be raised to any height within them. The French railways use a "monkey" (falling weight) of 440lb., with a drop of 11ft. 6in., the supports being 3ft. 7¼in. apart, the anvil weighing 10 tons. Messrs. Cammell use a weight of one ton, a fall of 20ft. or 30ft., and a span of 3ft. Rigidity and inertia of anvil are of considerable importance, but the chief difficulty is to attain constant rigidity. The Pennsylvania Railroad place their anvil, weighing 17,500lb., upon 12 stiff helical springs, each having two coils of 8in. and 5in. diameter respectively; the outer one is $1\frac{3}{16}$in. steel and the inner of $\frac{13}{16}$in. steel, 9½in. long uncompressed and 5½in. compressed. These can support 80,000lb. and exert a constant resistance whatever the condition of the ground. The monkey weighs 1,640lb., its maximum fall being 43ft., and the span 3ft. (for axle testing). It is specified that the axles shall not deflect more than 5½in. with the first blow delivered from a height of 23½ft., and shall stand five blows before fracture.) Some 300 of the above axles were put in service, and in the course of two years the journals began to fail from detail fracture. The matter was serious, and a consultation was held how to meet the difficulty. There seemed two ways of procedure, either to increase the size or to change the nature of the metal. Since an increase in size meant a redesign of all the parts, the latter alternative was chosen, and a metal of 80,000lb. tensile strength was substituted for the softer steel, no other changes being made. This completely cured the difficulty, and no other case of detail fracture in car axles is known to have occurred since that time, unless the metal was of lower tensile strength than the figure given, or the axle was worn to limit, so that the maximum fibre stresses was too high. To obtain the best results, the carbon limits should be increased from ·35 and 50 per cent. to ·40 and ·55 per cent. This would ensure greater wear, permitting a higher polish with a consequent reduction of friction and, if properly treated, greater strength, but would necessitate a modification of the drop test. All axles should be thoroughly annealed, as by this method only the true strength of the steel is represented. The axle should be smooth forged between the wheel fits; rough turning between the wheel fits robs the axle of the tough surface skin, which is a valuable asset —H. E. H.

Answer to No. 714 (*awarded* 5*s.*). — The causes of broken car axles have, I believe, been discussed in these columns on one or two occasions. The probable causes have been said to be caused by electrolytic action due to dampness and the return current, weakness in construction, and crystallisation of the metal. In most cases, the axle appears to break at the keyway or the shoulders, and is undoubtedly caused by resilience due to the enormous strains and shocks which the axle is subjected to in passing over uneven rail joints, curves, and other irregularities in the track. The breakage may, therefore, be put down to weakness in construction. The testing of axles appears to the writer to be useless, as the strains brought upon them under the actual working conditions are practically unlimited, and may be many times in excess of the strain when testing. The question is, "Why should the axles break in the same place every time?" Because they are weak in the place where they are subjected to the greatest strain. The cause of breakage is obvious, therefore apply the remedy and put more material in the weak part. All shoulders and sharp corners should be avoided in axles, and from the above observations it would appear that an axle of even diameter over its full length would be much stronger; collars could be shrunk on to take the place of the shoulders at present turned out of the solid. I saw some experiments on new car axles some time ago, also the fractures that had taken place on some at the shoulders during actual working conditions. The experiments were made on similar new axles, and had fractures very nearly like the old ones. It was found that those axles which had been in stock for two years stood a better test than those a few days old, which seems to prove that crystallisation is not the cause of the fracture, but rather that the effect of age is to increase the strength of the axle. Crystallisation in axles seems to be fallacious. Probably the crystallisation spoken of at the boss of the wheel is actually corrosion caused by the accumulation of mud, which, as a rule, contains a quantity of mineral matter made up of acids, etc. The following has been found to check the trouble: dissolve 1oz. of camphor in 1lb. of melted lard; remove the scum that forms; mix as much blacklead with the lard and camphor as will give it an iron colour; clean the parts well, and smear with the mixture. This should be done frequently, cleaning the parts every time before applying the fresh mixture. Larger quantities can be made up in equal proportions.—J. W. W.

REVIEWS.

Die Prufung von Gleichstrommaschinen (The Testing of Direct-Current Machines). By C. KINZBRUNNER. Julius Springer, Berlin. Price 9 marks. 390 pp., 249 illustrations.

This book, though in German, is based on the author's course of instruction to students of the Manchester School of Technology, and is more especially intended for the use of students of the higher technical colleges, although the treatment has intentionally been made elementary enough to meet the requirements of test-room assistants and others engaged in the practical work of testing. A knowledge of the ordinary theory of direct-current machinery and a general acquaintance with methods of electrical measurement are, however, assumed. Chapter I. gives some useful general hints as to the systematic carrying out of tests, the arrangement of regulating, starting, and loading resistances, and the choice of instruments. Though stating that "the value of a test depends particularly on the right choice and treatment of the instruments," the author gives only a short and somewhat incomplete description of the various necessary instruments, and makes no attempt to explain how to check or calibrate them. Chapters II., III., IV., and V. deal respectively with the measurement of resistance, temperature, insulation, and speed, and in the remaining six chapters the various actual tests are considered in detail. These include the determination of open circuit and load characteristics, magnetic leakage coefficients, the shapes of field and potential curves, and the various losses and efficiencies.

In dealing with the latter, a somewhat undue prominence is given to the various mechanical and eddy-current brake methods, whilst the Hopkinson and allied methods are dismissed with a very cursory treatment. The author considers that the difference in the magnetic conditions of the two machines under test vitiates the assumption of equal efficiencies. Considering that these methods are employed, in England at least, far more often than any other for the determination of the efficiencies of medium sized and large machines, the opinion is hardly justified.

Towards the end of the book a reprint of the standard rating and testing rules of the Verband Deutscher Elektrotechniker is given, and these rules are referred to throughout the book. The index provided is meagre, but this is more or less compensated for by a detailed table of contents.

In spite of slight blemishes of this sort, the book should prove of great use to the test-room assistant (especially if it is followed by a similar book dealing with alternate-current work), as the methods of test and the practical difficulties to be met with are clearly and fully described, and the diagrams are simple and plentiful.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

QUESTIONS.

725. A double-cylinder, double-acting, high-speed steam-engine of 320 i.h.p. is found from consumption test to require 42·5lb. of steam per indicated horse-power hour. It exhausts against a pressure of 12lb. per square inch above atmosphere. Initial pressure of steam in the engine cylinders is 80lb. per square inch. The mechanical equivalent in foot-pounds of the heat liberated by the fall in pressure from 80lb. to 12lb. is not equal to more than half the 33,000 foot-pounds of work actually performed. As the heat units required must be from theoretical considerations more than the equivalent of 1 h.p., explain why the work performed is apparently in excess of the heat utilised.—E. G. B.

726. On Aug. 8 the North-Eastern Railway Company commenced an electric autocar service between Scarborough and Filey, and the other day I had the pleasure of a trip by it. The car generates its own current. A gas or petrol engine drives two dynamos, one for power the other for lighting. I didn't notice any accumulator. Can anyone furnish me with a full description of the above and discuss the advantages of converting the gas-engine power into electrical power.—FILEY.

727. State how to enter the navy as an electrician, the duties of same, and the prospects.—H. W. H.

ANSWERS.

Question No. 715.—Explain the principle underlying and give sketch showing the connections of starters for single and two phase alternate-current motors from 4 h.p. to 30 h.p. I do not refer to liquid starters, but to those made by the E.C.C., which have a two-way marked "start" and "load," and appear to be some sort of transformer device.

Answer to No. 715 (*awarded* 10*s.*).—It is well known that if you start an induction motor with a short-circuited rotor,

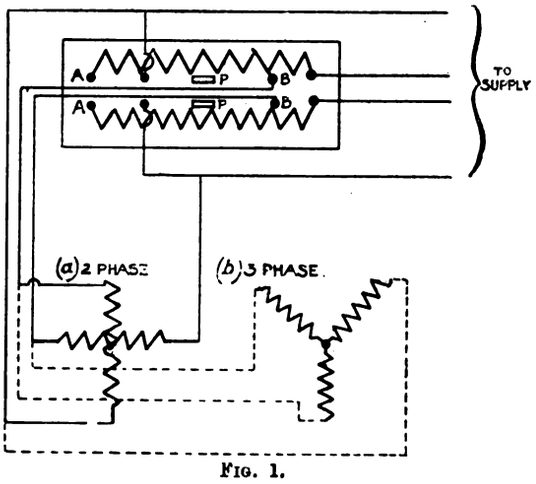

FIG. 1.

by switching it right on to the mains, a very large rush of current will take place in the stator, due to the heavy induced currents in the rotor. In order to check this rush, some sort of starting device is used, and placed between the stator and the mains, and is so arranged that it can be cut out of circuit when the rotor has run up to a good speed. The usual device used is the type of one mentioned by "Direct Current," though 30 h.p. is rather high for this type of starter, 20 h.p. being about the highest as a rule. The starter shown in Fig. 1 is an auto-transformer, which, when switched into circuit at starting up, chokes down the volts of supply, and, therefore, the rush of current through the stator winding. The amount of volts choked down is determined by the position of the tapping from the winding of the auto-transformer. The blades of the switch, which are pivoted at P, are thrown over to the left when starting, so put the coils from A to B in circuit and to the right when the motor has come up to a good speed, which cuts out the coils and connects right on to the mains; (*a*) shows connections for a two-phase stator; (*b*) shows connections for a three-phase star-connected stator.

There is another way, and one which is used for starting up rotors of larger horse-power, say anything from 20 h.p. upwards. This way is connecting resistance in the rotor circuit and connecting the stator right on to the mains. Leads from the rotor windings are brought through the shaft and fixed to slip-rings on the end; these in turn are connected by brushes to the resistances; these resistances are cut out step by step, thereby gradually short-circuiting the rotor. With this type of starter you get a much higher starting torque, on account of the increased slip due to the high resistance of the rotor circuit. Fig. 2 shows connections for such a starter for a three-phase motor with a three-phase wound rotor. The following is a simple way of finding the correct amount for such a starting resistance. Suppose the rotor to have a three-phase star winding, as in Fig. 2. Let r = the resistance per phase of

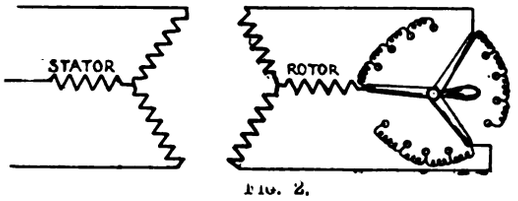

FIG. 2.

rotor winding; x = the resistance per phase of required starting resistance; c = full-load current per phase in rotor, which can be found from a Heyland diagram. Suppose the maximum starting current is not to exceed the full-load value—*i.e.*, stator current at starting = the stator current corresponding to c rotor current.

$\sim_1$ = periodicity of supply in periods per second.

$$\sim_2 = \frac{\text{R.P.M. at full load speed} \times \text{No. of poles}}{120}$$

$\sim_1 - \sim_2$ = slip in periods per second.

Then the volts induced in the rotor windings at starting must = $C(r+x)$ ohmic lost volts + $f \times c \times \sim_1$ inductive back volts (f being some constant). At normal full load speed the periodicity of the rotor currents = $\sim_1 - \sim_2$, and as the rotor is short-circuited, the ohmic loss and the inductive reaction will now be Cr and $f\,c(\sim_1 - \sim_2)$, and since the ratio of the reactive volts to the resistance volts remains practically constant we may say

$$\frac{f\,c \sim_1}{C\,(r+x)} = \frac{f\,c\,(\sim_2)}{Cr}, \text{ or } x = r\left(\frac{\sim_1}{\sim_1 - \sim_2} - 1\right).$$

With about 5 per cent. slip this gives $x = 20\,r$, and in practice $x = 30$ or $40\,r$, so as to reduce the starting current (and torque) below the full-load values. If the value of x given

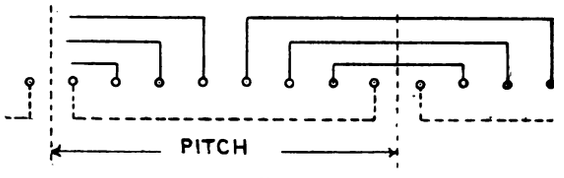

FIG. 3

by the formula is used, the starting torque will be equal to the full-load running, and this is unnecessarily large for most cases. In dealing with polyphase motors, it is only a matter of how best to control the starting of them, but with single-phase motors it resolves itself into how to make them start, for a motor with only a single winding on its stator has no tendency to start from rest, though if you give it a slight rotary motion it will then run up to speed.

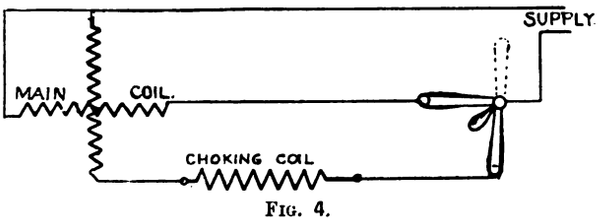

FIG. 4.

The difficulty is got over in practice by putting a special starting winding on the stator, which is cut out after the motor has come up to speed. With such an additional winding the motor can be started up as a two-phase motor, the main winding being connected direct to the supply mains, and the starting winding having a lagging or leading current supplied to it, it is sometimes wound in the same slots as the main winding and sometimes in intermediate ones, as shown in Fig. 3.

Fig. 4 shows the connections for a single-phase motor

Digitized by Google

starter. When the motor has got up a good speed the two-way switch is put into position marked by dotted lines, thereby cutting out the starting winding. The rotor, which would be a short-circuited one, is not shown. Messrs. Brown, Boveri, and Co. use a condenser instead of a choking coil, and so create a leading current in the starting winding.—POWER FACTOR.

Answer to No. 715 (*awarded* 7*s.* 6*d.*).—The Electrical Construction Company make induction motors up to fairly high powers with simple squirrel-cage rotors, and for starting up these machines have adopted the method—much favoured by the Americans—of the "auto-transformer."

FIG. 1.

An auto-transformer is really a choking coil made with a closed iron circuit as with the ordinary transformer, but also with tappings off from various points in the winding, so that a lower voltage is available. The action of the auto-transformer under load is clearly seen by reference to the accompanying Fig. 1. There is a voltage drop all along the windings from A, and the voltage to any point C is proportional to the number of turns between A and C. If now A and C are connected together through a resistance, current will flow through this resistance; and this current will be made up partly of current flowing in from B to C and partly of current flowing from A to C produced by the transformer action of the coils B C on the coils A C.

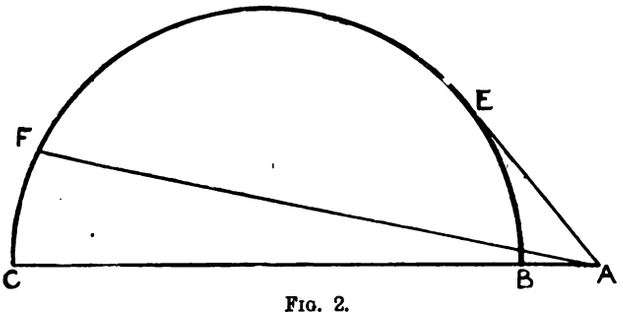

FIG. 2.

The actual values of these currents will be such that their arithmetical sum is the currents which flows through the resistance, and also the ampere-turns between A and C will be equal and opposite to the ampere-turns between C and B As an example, suppose volts across A B be 200, and volts across A C be 72. Then, if the current flowing through the resistance be 79, the currents in the sections A C and C B will be

$$79 \times \frac{72}{200} = 28{\cdot}5, \text{ and } 79 \times \frac{128}{200} = 50{\cdot}5.$$

We have discussed the action of the auto-transformer, and will now consider the behaviour of the motor under a

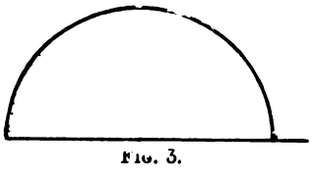

FIG. 3.

lowered voltage. Fig. 2 represents the circle diagram of an induction motor at full voltage. A B is the magnetising current necessary for this voltage, and as the iron parts of the motor are not all saturated, the magnetising current for other voltages will be proportional. For the same reason, the leakage at any lower voltage will be the same, and so the diagram of motor at half the voltage will be as shown in Fig. 3. In this, for similar points on the semi-circle, the currents are decreased by half, but it must be borne in mind that the torque, which is proportional to (load current × magnetising current), is proportional to square of voltage, and in this case is reduced to one quarter. The current which flows when the voltage is first applied to a squirrel-cage motor is known as the short-circuit current (A F), and the problem is to so reduce the voltage applied to motor at start that the line corresponding to A F in new diagram is a given number of times full load normal current (generally between 1·5 to 2 times). (The short-circuit current is best obtained by experiment at a lower voltage than motor is built for, and then increasing in proportion.)

We will take a concrete case of a 20-h p. two-phase motor, working on a 200-volt circuit at 50 ~, and taking 45 amperes per phase at full load. When tested for short-circuit on 55 volts the current was 60·5 amperes. It is stipulated that 1¾ full-load current is allowed at starting.

Short-circuit current at full voltage will be

$$\frac{60{\cdot}5 \times 200}{55} = 220 \text{ amperes.}$$

∴ Reduction of voltage for starting will be

$$\frac{1{\cdot}75 \times 45}{220} = \frac{1}{2{\cdot}8} \text{—}i.e.\text{, to 72 volts.}$$

The currents in the coils have already been worked out for this case, and they are: 50·5 amperes in the coil giving 72 volts, and 28·5 amperes in the coil giving 128 volts.

As the auto-transformer will only be used for starting, the flux and current densities must be made much greater than is usually the case. The accompanying sketch indicates a suitable design for this case, and it will be found that the flux density is somewhere about 60,000 lines per square inch, and the current densities are about 3,200 amperes per square inch. It will be noted that as the ampere-turns between A and C are equal and opposite to the ampere-turns between C and B, the two coils will both occupy about the same space, although, of course, they are wound with different sizes of wire. The arrangement of connections on the starting and running contacts is shown in Fig. 4.

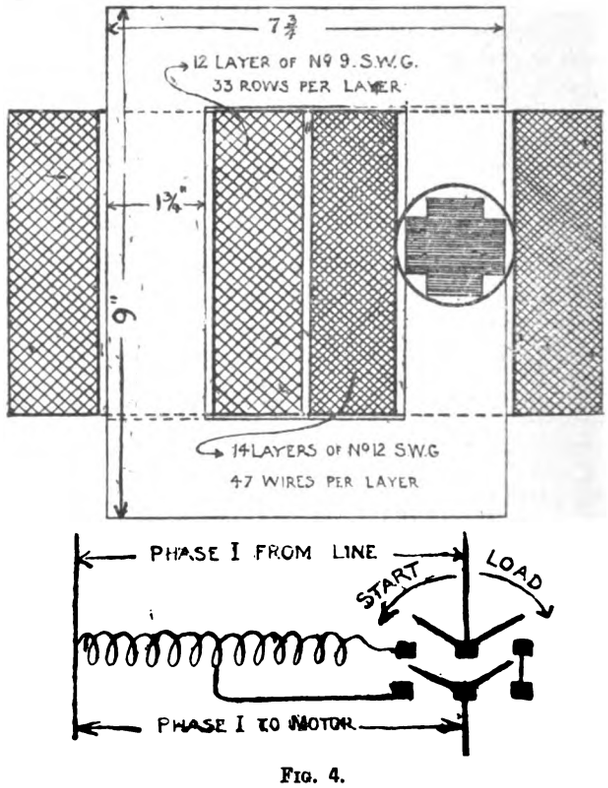

FIG. 4.

With regard to the starting of single-phase motors, other devices than those for cutting down the initial current are required, and, judging from the reference to liquid starters in the question, a description of these other devices is not required.—X. Y. Z.

Answer to No. 715 (*awarded* 7*s.* 6*d.*).—The principles underlying starters for single-phase and for two-phase motors are entirely different, and must be dealt with separately. In the case of a two-phase motor, nothing further in the way of a rotating switch is really required than a simple three-pole main switch (Fig. 1). Switching the motor direct on in this way, however, involves a considerable initial rush of current, owing to the rotor, when at rest, acting as the short-circuited secondary of a transformer, of which the stator winding is the primary. When

Digitized by Google

only a low starting torque is required from the motor, this rush can be reduced by reducing the terminal volts whilst starting. This is usually accomplished by means of an auto-transformer and a special throw-over switch. An auto-transformer is simply an ordinary transformer with a single winding, the primary volts being connected across the whole of this winding, and one secondary connection being at one end of the same winding and the other secondary connection at some intermediate point along the winding, according to the ratio of transformation required. For small ratios of transformation this arrangement considerably reduces the size of the transformer, since a

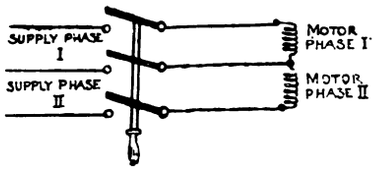

FIG. 1

part of the winding is common to both primary and secondary. When used for starting purposes, the ratio of transformation is usually made about 2 : 1—*i.e.*, the terminal volts at starting are reduced to half the normal supply voltage. The connections of such a two-phase starter are shown in Fig. 2. The switch would usually be of the throw-over chopper type, and is shown diagrammatically only. When the switch is moved upwards to the "starting" side, the arm, *a*, connects the free ends of the two auto-transformers to the middle wire, thus putting the transformers into circuit, and at the same time the three other arms connect half the transformer windings to

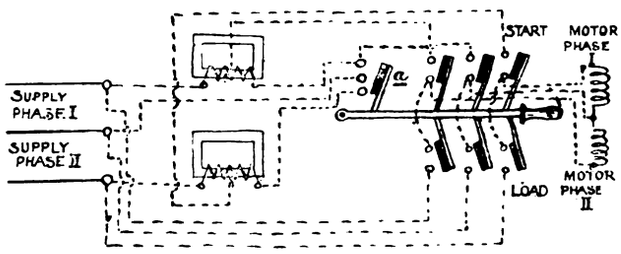

FIG. 2.

the two phases of the motor stator winding, thus starting the motor at half normal volts. As soon as the motor has obtained full speed the switch is moved over on to the "load" side, and this open circuits both the transformers at *a*, and so avoids all core losses, and at the same time the full supply voltage is switched on to the stator windings. The diagram is shown for a three-wire supply, but with very little modification is applicable to a four-wire supply, the switch remaining unaltered. The two separate single-phase transformers shown would usually be combined into a single three-limbed two-phase transformer. The switch given is equally adapted for starting three-phase motors.

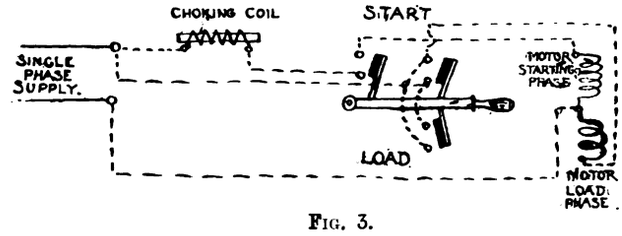

FIG. 3.

Turning next to the case of a single-phase motor, the principal object of the starter in this case is the production of the necessary phase displacement between the currents in the starting and load phases of the motor. Such a phase displacement is necessary in order to make a single-phase induction motor start at all, and it is very usually obtained by inserting a certain amount of inductance in the form of a choking coil into the starting phase winding. The arrangement for this is shown in Fig. 3. When on the "starting" side, the switch puts the load winding of the stator direct on to the supply mains, and the starting phase on to the mains through the choking coil. When the switch is moved over on to the "load" side, the starting phase winding is entirely cut out, but the load winding is still left connected across the mains.

Many other methods of obtaining the phase displacement have been employed, such as the use of a condenser in place of a choking coil, or simply inserting a non-inductive resistance in circuit with the load winding and connecting the starting winding direct across the mains, and so on, but the above arrangement with a choking coil is the one most commonly met with.—Q.

Answer to No. 715 (*awarded* 5*s.*).—"Direct Current" must have evidently made a mistake when he mentioned two-phase motors, as these do not require any special start-

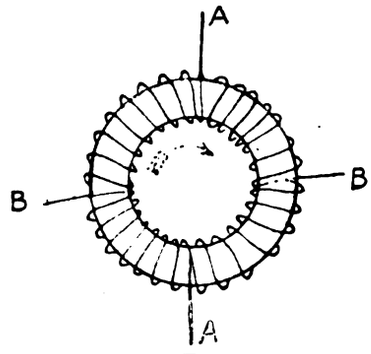

FIG. 1.

ing arrangement such as he mentions, so we will deal with the single-phase motor. If two equal alternating currents, differing in phase by a quarter of a period, are properly combined, they can be made to produce a rotary magnetic field, and in such a rotary field conductors can be set rotating. Consider Fig. 1. If a single alternating current were introduced at the points A A_1 it would set up an oscillatory magnetic field, a N pole growing at A and a S pole at A_1, then dying away and reversing in direction. Similarly, if another alternate current were introduced at B B_1 it would produce another oscillatory field in the B B_1 diameter. If both these currents were set to work, but timed so that the B B_1 current is one quarter period behind the A A_1 current, then they will combine to produce a rotary magnetic field, though the coil itself stands still. This is quite analogous to the well-known way in which a

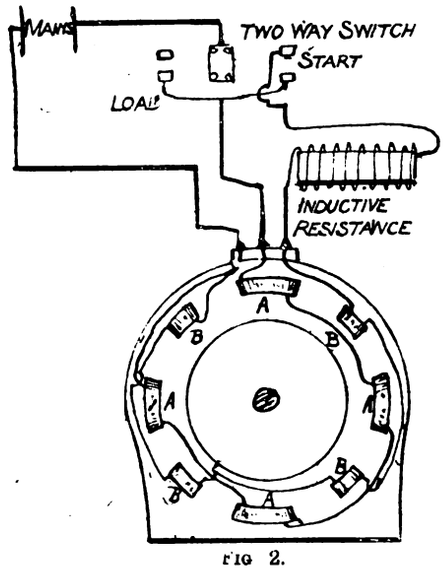

FIG 2.

rotary motion can be produced from two oscillatory motions by using two cranks at right angles to one another, the impulses being given a quarter period one after the other. In such rotating magnetic fields masses of metal at once begin to rotate. Any pivoted mass of good conducting metal, such as copper, will also be set in motion and will be self-starting. In such a centred mass or rotor eddy currents are set up which drag the metal mass and tend to turn it, but if only one phase was in action—say, the A A_1 part—the field would only oscillate and not rotate; and any currents generated in the rotor will be equal and opposite in direction, and, therefore, there will be no tendency to move. We can come back to our old

Digitized by Google

analogy of the single-crank engine, which when on a dead centre will not start, but when set running at a speed high enough to carry it past the dead centre, will continue to run.

From the above it will be seen that it is necessary to get the single-phase motor running before applying load, and also a method is given of getting it running. The method is of splitting or diphasing the current in the stator, and thus getting a rotating field. In any book on alternating current it is shown that if an alternating current is passed through a circuit containing self-induction, the current will lag behind or differ in phase with the E.M.F., or if the circuit possesses capacity, the current will lead or differ in phase with the E.M.F. With the foregoing, Figs. 2 and 3 will now be understood. A is the running winding, B is the auxiliary starting winding, in the circuit of which is a self-induction and capacity respectively. Winding A possesses as little self-induction as is possible, so that the current will be practically in phase with the E.M.F., whereas winding B has either a self-induction or capacity which will cause a phase displacement, and therefore it will start up as a two-phase motor. Of course the phase displacement is not 90deg., but it is sufficient to produce a rotating field. Some makers modify the above by putting a capacity in the running winding circuit, besides a self-induction in the starting winding. All motors of this type

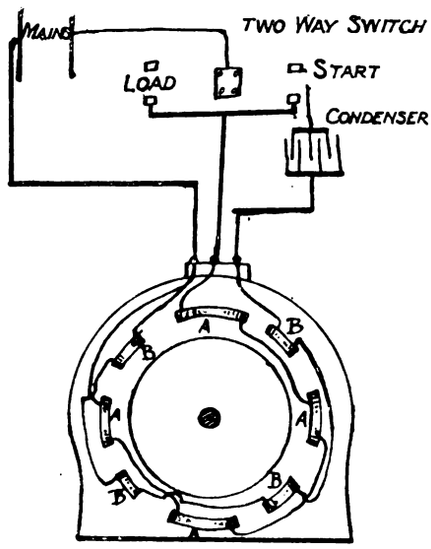

FIG. 3.

above 5 h.p. should have a starting resistance in the rotor circuit, but as this is off the point we will leave it, but if "Direct Current" wishes to go further I would recommend Hay's "Alternate-Current Working," published by Biggs and Co. at 5s.—A. W.

Answer to No. 715 (*awarded* 5*s.*).—In order to start a single-phase induction motor it is necessary to produce a rotary magnetic field, so that while starting the motor has to be fed with two separate currents lagging in phase. If a two-phase motor is running light, and one phase is suddenly switched off, the motor still continues to run at nearly the same speed, but the phase that is still being fed will now draw double the current. The reason of this is that, if a two-phase rotary field has been started, induced currents are set up in the rotor conductors which set up a magnetic flux in the air-gap. When one phase is switched out, the remaining phase still goes on producing a magnetic flux; and since the induced magnetising currents in the rotor are in quadrature with the flux produced by the supply current, and are carried forward nearly 90deg. by the practically synchronous rotation of the rotor before they reach their maximum values, it will be clear that the flux produced by the switched-out phase is now practically replaced, and so the motor continues to run with the single phase only. Single-phase motors that are started in this manner must obviously have two windings, one of which is used for starting only, while the other is permanently connected across the mains while running. Fig. 1 shows these two windings, A A and B B. Suppose A A to be the running coils, and B B the starting; then, to produce a rotary magnetic field, it will be necessary for the current in the B B coils to lag by 90deg. In order to cause this lag, or something as near to it as possible, a phase-splitter is introduced into the circuit, which usually consists of a choking coil or condenser in series with one branch, and a non-inductive resistance in series with the other. It will be seen that when the starting switch is on the contacts marked 1, we have a choking coil in series with the A A windings, and a non-inductive resistance in series with B B. When the motor comes up to speed, the switch is then thrown on to the contact 2, which cuts out both the choking coil and non-inductive resistance, and connects the A A winding straight across the mains, leaving the B B winding idle.

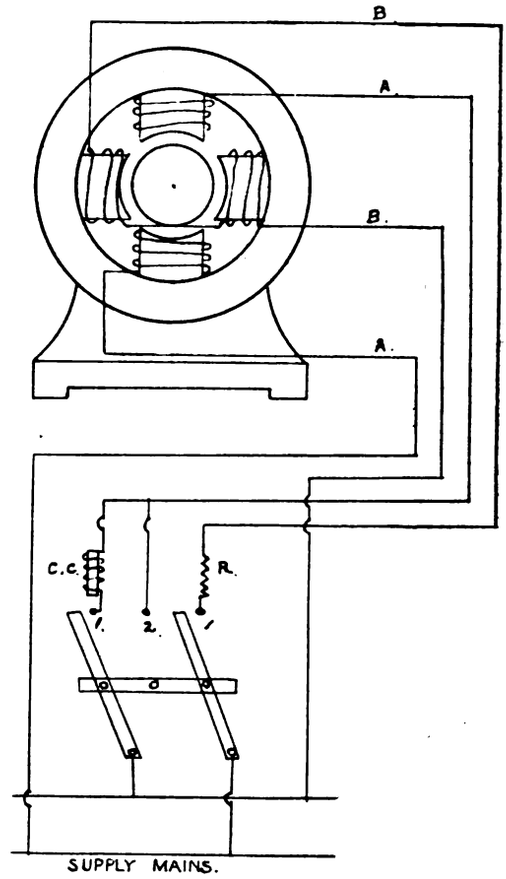

FIG. 1.

In dealing with starters for polyphase motors, matters become far less complicated, for since we already have a rotary field, phase-splitting devices can, of course, be dispensed with. There are two methods of starting these motors, one of which simply consists of reducing the pressure at the terminals, in the same way that a direct-current motor is started, but in this case the reduced pressure is brought about by a small transformer. On starting, the primary of the transformer is switched on to the mains, while the motor is already connected to the secondary. When the motor has gained speed, the switch is then thrown over on to a second set of contacts, which cuts the transformer out of circuit and joins the motor straight across the mains. This method is only used where a large starting torque is not necessary. In cases where a heavy starting torque is required a resistance is placed in series with the rotor windings and gradually cut out on starting. If we consider the induction motor as a transformer, it is a very simple matter to see how this arrangement prevents the motor drawing abnormal currents. Consider the stator windings as the primary, and the rotor the secondary. Now, in the ordinary way, the rotor windings are short-circuited; therefore, if the stator be switched on to the mains, we get the same result as if we switch in a transformer whose secondary is short-circuited—that is, it draws a very heavy current—but if the ends of the stator be first joined with a fairly high resistance and then gradually cut out, this heavy starting current will be obviously avoided. There is one rather bad point about this method which rather spoils the good properties of the induction motor—that is, it necessitates the use of slip-rings.—E. AUSTIN.

Supplement to "The Electrical Engineer,"
SEPTEMBER 23, 1904.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

728. A house wiring specification calls for all casing under floors to be "half mitred and screwed." Give particulars, with sketches, of requirements, mentioning any other method ensuring a firm and workmanlike job.—J. E. H.

729. Much trouble has been experienced with various hand-wound armatures, on which wire of 18 S.W.G. and smaller has been employed, owing to breaking of end connections while running. The breaks always occur within ½in. of the end of the core and in the *straight* wires. Please explain the cause of the trouble and suggest remedies.—A. B. D.

ANSWERS.

Question No. 716.—In inspecting Lancashire boilers, what are the chief places to watch for defects?

Best Answer to No. 716 (*awarded* 10*s.*).—As a preliminary survey, prior to one of a more exacting nature, the boiler might be carefully gone over, while under usual working conditions, with a full head of steam. This survey will betray to the inspector any weeping joints or rivets, cracks in brickwork affecting draught, or crevices between the boiler plates and setting, permitting the collection of water emanating from roof leakage or other sources. The quality of the feed water may then be ascertained, also some knowledge of the usage to which the boiler is subjected, and whether the safety valve operates at the critical pressure may be observed. Frequently cracks in the brickwork setting will be noticed when everything is heated, which would otherwise remain unseen after the boiler has cooled down and all materials contracted to normal dimensions. On shutting down, and due time having been allowed, after running the water off, to permit the plates having cooled sufficiently, an internal inspection should be made before cleaning operations are commenced; this opportunity should be taken to note the quantity and quality of the deposit or incrustation and its position in the boiler. Demand a thorough scraping of all the internal parts, that all scale and sediment be removed, particularly about the rivet-heads and end plates, and all seams below water-level. On the outside, dust and soot should be removed from the flues, and the boiler plates directly in contact with flame or hot gases be carefully cleaned. Have portions of the brickwork pulled down where the boiler plates are in junction with the setting; the feed-water valve and blow-off cock might be dismantled from their positions. The following places may then be systematically gone over.

Internally.—Along the water-line—this line being the position about which the water-level varies under working conditions—the boiler plates should be lightly tapped with a small round-nosed hammer, each series of tappings being followed by the inspector's finger to learn, by the sense of touch, what impression is being made on the plates. If the impression is deep, the plates will be found to have thinned by repeated corrosive scaling or pitting. The sound produced by each hammer-blow will act as an additional guide to the condition of the plates, the average ear very readily detecting a dull from a sharp bell-like ring. The furnace tube crowns may next be gone over in a similar manner with light blows of the hammer. Any thinning of the metal, hogging of the flues, or signs of collapse will be instantly noted. Should there be fusible plugs in the furnace crown, their removal and a renewal of the fusible alloy is recommended before being replaced. Attention may in turn be paid to the thoroughfares of all gauges and cocks, a thick wire being used to clear out passages of the former. This part of the examination must be conscientiously performed, the serious results ensuing from choked gauge apertures being obvious. Probably there will be some internal mechanism known as a high and low water alarm. This, if worked by hand several times, will bring to notice any mechanical defects and remove any stiffness in its operation. The boiler seams below water-level are of vital importance, and time is not lost in examining these. To illustrate the nature of faults to be met with in the vicinity of boiler seams, the accompanying sketches may be useful. In

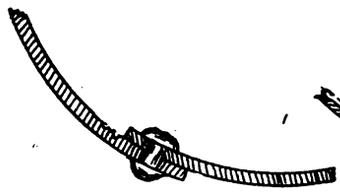

FIG. 1.

FIG. 2.

Fig. 1 the corrosive grooving has been started by the alteration of the boiler's shape during expansion, being localised at this seam. In Fig. 2 excessive scaling, due to corrosion, has caused the plates to thin dangerously and utterly destroyed the rivet head; and in Fig. 3 pitting and grooving in the vicinity of the working water-level. By sharp blows of the hammer on the longitudinal tiebars defects or fractures would instantly be noted, and by tapping the internal nuts their tightness would be assured. On the surface of the bottom plates, where most sediment would collect, the hammer should again be applied throughout the entire length of the boiler to detect any signs of deterioration.

External Examination.—There is little doubt but that many boiler failures can be attributed to exterior corrosive action, hence the need for carefully surveying the following places. Immediately in the vicinity of the manhole or mudhole doors and all flanges fitted to the boiler plates a careful scrutiny is necessary. A tiny leak at a joint, allowing a jet of stream to escape, given sufficient time,

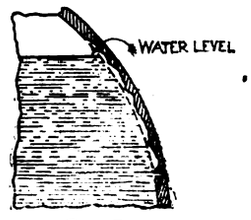

FIG. 3.

will cause serious pitting to result; the escaping steam, having been condensed on coming into contact with the atmosphere, falls as drops of water, which simmer on the heated plates. Particular attention should be paid to the joint between the boiler plate and flange of the feed-water valve, as, due to the expansion and contraction in the vicinity of the metals, leaks are likely to occur. At the commencement of this reply it should have been stated that any non-conducting composition on the boiler crown is presumably so applied as to permit ready accessibility to the plates for inspection. The removal of this covering should be rigidly insisted on, for it serves in many instances to hide a multitude of sins. On the boiler crown leaks from steam-pipe joints should be looked for, also the possibility of influx of rain-water through openings in the roof likely to fall about the boiler or brick setting. It would be well while the inspector is at this position to have the safety valve and stop-valve opened up, and, if necessary, the valves ground on their seats; this is applicable to all cocks

Digitized by Google

or valves about the boiler fittings. The blow-off cock might come in for special notice, as boilers have been known to empty due to defective blow-off cocks. The pipe bend connecting this cock to the boiler bottom ought to be given ample space to expand, and not be built rigid in brickwork, as it often is, or held fast with damp ashes Entering the furnace tubes, the hammer might be brought into requisition and applied as at other parts, a sharp look-out being kept for blistering of the plate surfaces due to overheating. In the neighbourhood of the end plates, where the furnace tubes are attached, special attention may be directed, as it is here the flame and hot gases curve round on their way to the brick flue underneath. Following this latter flue, the same manner of investigation is continued, combined with an observation of the seating blocks, on which the boiler rests, to determine if the weight is evenly distributed thereon. Continuing along, in turn, each of the side flues, the general examination of the exposed boiler plates is made, and where the brickwork has been pulled down a rather more careful inspection is necessary to learn if corrosion of the plates has taken place, caused by their being in contact with damp brickwork or water leakage from other sources. If the flues are discovered to be damp, the inspection should enquire into the reason. The damper door should not be passed over. Its condition will be noted, and whether it is likely to be efficient in regulating draught Signs of the brick arches in the flues giving way are to be carefully looked for, as a complete shut-down of the boiler would result if either of the arches collapsed. With many firemen it is customary to pull out ashes from the furnace and slack them whilst lying against the front end plate; severe corrosion results from such practice; the inspector would do well to examine the lower part of this end plate, and if deterioration of the plate is noticed the cause is that just mentioned, therefore instructions to slack ashes at some distance from the boiler should be given. In the event of any doubt existing regarding the thickness of any plate, showing signs of severe pitting or scaling, a small test hole might be drilled through the plate, and on the dimension being taken a screwed taper plug is introduced to fill the hole. Having completed the survey, if considered advisable, a pressure test can be applied; the boiler being filled with water at a temperature of from 180deg. to 208deg. F., and the pressure raised to 50 per cent. above that of working, after the plates have absorbed sufficient heat from the water to permit of uniform expansion. While the pressure test is being applied, it is expedient that a standard hydraulic pressure gauge be used in conjunction with the gauge belonging to the boiler, thus ensuring a reliable indication of the pressure, and also acting as a test of the latter gauge for its accuracy.

Summarising briefly the places to be examined herein mentioned, they are:

Internal.—(1) All plates along the water-line or working level, including end plates; (2) the furnace tube crowns; (3) fusible plugs on furnace crowns; (4) apertures to all cocks, gauges, and valves to be thoroughly cleared; (5) high and low water alarm (if any); (6) longitudinal tiebars, including fastening nuts at the end plates; (7) all boiler seams below water-level; (8) surface of bottom plates, where sediment is most likely to collect.

External.—(1) The immediate vicinity of all manhole or mudhole doors and flanges fitted to the boiler plates; (2) possible leakage from boiler-house roof or steam-pipe joints; (3) all exposed plate surfaces in flues affected directly by flame or hot gases; (4) the furnace tubes; (5) seating blocks for even distribution of the boiler's weight thereon; (6) where brickwork setting is in contact with the boiler plates, and where such has been removed; (7) dampness in flues; (8) safety valve and stop valve, blow-off cock particularly, and other fittings; (9) damper door and brickwork arches in flues; (10) pressure gauge to be tested under conditions stated.—WALLSEND-ON-TYNE.

Answer to No. 716 (*awarded* 7*s.* 6*d.*).—The inspection of a Lancashire boiler, to be complete, must comprise—as one of the leading boiler insurance companies directs—an external, an internal, and a flue examination. The first deals with the external condition of the shell and furnace crown, and with the fittings, and should be made both when the boiler is under pressure and at rest. The second deals with the surfaces of plates, etc., usually in contact with steam and water, and also with the internal fittings. The last deals with the surfaces of plates, etc., usually exposed to the action of the flames or gases, and also with the brickwork flues.

The preparation of a boiler for inspection is a matter of considerable moment, and the following points should be noted: (1) the flues should be cleaned, and all soot, etc., brushed off the plates and rivets—if the boiler is set on mid-feather and wide seating walls, pockets should be cut so as to expose for inspection the rivets in the ring seams; (2) the inside of the boiler should be cleaned, and all scale, etc., removed; (3) the firebars and bridges should be removed, and all manholes, etc., opened for access to boiler and flues. The above are the general instructions for inspection and the preparation therefor; the inspector, while carefully examining the whole of the boiler, will give most attention to certain portions which are usually found to develop defects.

In an installation of 12 Lancashire boilers working under somewhat trying conditions it has been noticed that defects have developed in similar places in each boiler. The boilers have been working some 10 years, and are worked at a pressure of 130lb. They are fed with condensed water from the engines, and until some two years ago have shown more than traces of oil. They are fitted with mechanical stokers, and have been, at times, forced much beyond their normal capacity. As stated above, defects have been found to develop almost invariably in similar places in each boiler; these places are enumerated below, and may be thus classified as found in the inspections:

External and Flue Examination.—(1) In the shell: (*a*) ring seams, leakage and local wasting round the rivets especially in the flues; (*b*) front shell angle-iron, leakage in the lower part and consequent local wasting round the rivets. (2) In the furnace and flue tubes: (*a*) distortion and bulging of furnaces, especially in the second and third rings; (*b*) flanged seams of the furnaces, leakage especially in the first three seams; (*c*) welds of the water-pipes, leakage. (3) In the flues, seatings, etc.: (*a*) seating blocks and mid-feather wall; (*b*) down-take cover blocks.

Internal Examination.—(1) In the shell pitting through corrosion should be watched for, especially in the lower part of the shells; grease should be also sought for. (2) In the furnace and flue tubes, as in (1), pitting here usually in the crown and grease should be watched for. (3) Stays should be examined.

The above are the chief places to examine for defects; the most important are the furnaces and shell, as set forth in the flue examination (1), (*a*) and (*b*), and (2), (*a*) and (*b*). The bulges or distortion of the furnaces must be most carefully measured, and templates should be kept and tried from time to time to note the progress of such distortions. The boiler mountings call for careful examination. Pressure gauges should be periodically tested, safety valves, alarms, water and blow-off valves and gauges regularly overhauled.—S. E. T.

Answer to No. 716 (*awarded* 7*s.* 6*d*).—From the moment a boiler is finished it gradually becomes weaker, due to the destroying forces that are continually acting upon it. These forces are of both chemical and mechanical nature, and keep up their action with an ever-increasing rapidity. Corrosion, which takes place both internally and externally, is the most serious and subtle cause of weakening to which a boiler is subjected. Internal corrosion is generally in the form of wasting, of pitting, and of grooving. This *wasting away* of the plates is seldom so uniform in its effects as rusting, but it usually covers large patches of surface. It is produced by some chemical action of the water on the plates, and is more or less easy of detection. Sometimes it produces "bleeding"—that is, the scale and plates in the vicinity are streaked with red. When wasting is very extended, it is apt to pass unnoticed in a hasty examination, but it is always revealed by dulling the plate and calipering. This precaution of dulling should always be resorted to with old boilers. There are no rules to guide the inspector in searching for wasting, and it does not

Digitized by Google

appear to take place in two boilers alike. However, the water-line appears to be especially liable to attack in boilers that stand quiet for a long while. For this reason boilers should not be allowed to stand idle when only partly filled with water. Sometimes this corrosion is hidden under a thin shell or crust of metal, when its presence can be detected by means of a testing hammer.

Pitting or honeycombing is in general well defined. It consists of small depressions of various shapes and forms. When the depressions are extended, the effect is more like wasting. It is not limited to any particular part of the boiler, and often appears in the steam space. The depressions are sometimes filled with a fine powder, being a mixture of iron, silica, and other earthy matters, and a small percentage of oil. These depressions are occasionally covered with a hard crust-like blister, but more frequently are open with sharp edges. Pitting is particularly likely to occur if a water very free from lime is used in a very clean boiler. When a boiler is one of a battery and is kept standing for a long interval, the top of the boiler is liable to pitting. Steam finds its way into the boiler, and, condensing upon the top surface, causes bad pitting there. Pure water, containing no air, does not harm, and steam alone will not cause pitting unless it contains a supply of air. Feed-water heaters often suffer badly from pitting, particularly near the cold-water inlet, and in boilers the parts most likely to be attacked are those where the circulation is bad, especially if such portions are also near the feed inlet.

Grooving occurs along the edges of laps, angle bars, stays, and cover plates. It is caused primarily by too great a stiffness, resisting expansion and contraction. This stiffness compels the play or breathing of the boiler to take place locally, similarly to bending backward and forward a thin plate with the hands. It is sometimes initiated through injury to the plates by a careless use of the caulking tool. In a crack once started grooving increases rapidly, due to the corrosive action entering deeply into the plate and exposing fresh surfaces. When cylindrical boiler shells are too firmly seated on their foundations, the expansion may promote grooving by causing the plate to buckle near the lap or butt straps, especially those of the transverse or ring seams. If the shell is not perfectly cylindrical, it tends to become so under pressure, and the longitudinal seams are similarly affected. To prevent grooving of the head or end plates at the flanges or angles where they join the shell, tubes, flues, and stays should not be located too near the shell; the flange should be turned with an easy radius about 2½ thicknesses, and the head should be made as thin as safety will permit.

Internal corrosion appears to be caused by acidity and air in the feed water, and perhaps, in special cases, to some form of galvanic action. Such galvanic action has been counteracted by the use of zinc plates. The electric couple separates the hydrogen, which passes to the steel and then escapes into the steam space, while the oxygen goes to the zinc. The proportions found requisite to ensure protection are about one square foot of zinc to 50 square feet of heating surface in the new boilers, and the same quantity of zinc to 75 or 100 square feet of surface in older boilers. The zinc plates should be about 10in. by 6in. by ½in., and the connection between the zinc and steel must be a good metallic contact to be effective. Usually the zinc is bolted to convenient stays or to studs formed for the purpose on the combustion chamber. The contact surfaces should be bright and clean, and the nuts should be well screwed down to prevent scale forming between them. The zinc slabs will last from two to three months. The zinc is sometimes carried in metal baskets to catch pieces that break off from time to time. The varied appearance and location of corrosion may be caused by the lack of either physical or chemical homogeneity in the metal. In order to prevent internal corrosion, the causes should be studied and neutralised as far as possible. The feed water should be kept slightly alkaline by the use of soda, and be free from air. A thin coating of scale will often act as a protective covering. When corrosion has attacked a surface that is not directly exposed to the fire or hot gases, it will often be found beneficial to clean the spot. Wash it with soda, and paint it with a thin layer of Portland cement. Wherever boilers are liable to excessive corrosion, they should be most carefully examined at regular intervals. This is true for external as well as internal corrosion.

External corrosion is just as active as internal corrosion, and in many ways more dangerous, since it is not so often suspected, and since boilers are frequently so set as to be difficult to inspect properly. The forms are similar to those of internal corrosion. It is generally produced by leaks or dampness and drippings from fittings. Ashes will rapidly corrode any metal against which they lie. In examining the fittings, the height of the bottom of the gauge glass (where the water disappears from view), and also the height of the feed pipe above the furnace crown, should be observed. The former should be about 3in. or 4in., so as to be sure that there is no danger from overheating so long as the fittings are in order and the water in sight. The position of the feed pipe is rather an important point. It should be so arranged that, in the event of a slight solid particle getting under the check feed valve, there is no risk of the water siphoning into another boiler connected to the same feed pipe and leaving the furnace crown bare. To reduce the risk of this occurrence, the opening of the feed pipe should not be more than 3in. or 4in. below the normal working level. If the boiler is fitted with a scum apparatus, the water-level at which the tap is intended to be opened is usually indicated by a pointer alongside the water-gauge. If this (the pointer) is too high, the troughs will not draw off the scum, and if too low, the tap will blow off steam and not water. To secure the best results, the water-level should be about ½in. above the top of the troughs. The level of the pointer, as well as the top of the scum trough, should be carefully measured, as the pointer frequently wants adjustment owing to carelessness in fixing when the boiler was put down. In this connection it should be noted that it is not sufficient to note that the troughs are the same height above the furnace tube throughout its length, as a boiler usually has a fall of about 1in. or 2in. in its length to enable it to drain empty when blown off, and hence, unless this point is watched when the troughs are fixed, they will not be truly water-level. In the case of bolt stays, it should be noted whether they are tightened up like a fiddle string, as they sometimes are, for if they are they are apt to distress the end plate by limiting the movement required by the furnace tubes for expansion, and cause leakage at the gusset and furnace, mouth rivets, and in extreme cases grooving, if the boiler is hard worked and subject to fluctuations of pressure. In old boilers the longitudinal stays are often secured with a pair of angle bars attached to the ends by means of an eye in the stay and a pin passing through the angle bars. In such cases the pin, as well as the angle bar, are liable to get fretted and seriously reduced in strength. Similar remarks apply also to the cotter or pin connections often found at the mid point of such stays.—H. E. H.

Answer to No. 716 (*awarded* 5*s.*).—Of the many defects which steam-boilers are liable to, grooving due to internal corrosion is certainly one of the most important. It usually occurs at the joints of the plates to each other, or to some fittings, or other parts of the boiler. Internally the effect is more generally due to the localisation of corrosion, owing to the fact that the plate at that part is subject to some bending action, tending to disintegrate the surface, and thus helping any corrosive action of the feed water. Externally the grooving is often due to leakage at, or adjacent to, the defective part, and unless there is brickwork or other materials in contact with the plates, the wasting is usually local. When lap seams are under compression, as in the longitudinal seams of furnace tubes of Lancashire boilers, grooving is frequently met with at the seams. This is probably due to the variations of steam pressure from time to time causing an alternate bending to and fro, rendering the plate adjacent to the lap more vulnerable, and with corrosive water frequently resulting in more or less severe grooving.

Cases of very peculiar grooving have been known to occur at the edge of the angle iron connecting the gusset stays to the shell plate. One of these is indicated in Fig. 1, a deep channel, G, being formed, extending the full length of the angle attaching the gusset plate to the shell. This

Digitized by Google

is probably caused by mechanical action, due to the gusset plate drawing the shell a little from the true circular form.

Grooving of the end plates above the furnaces is another very common defect in Lancashire boilers; it is generally more severe at the front than at the back end, and is due to bending of the end plates, owing to the expansion of the flue and furnace tubes. Where the ends are properly stayed such grooving is seldom dangerous, although it may necessitate expensive repairs. Fig. 2 illustrates a case of this grooving, in which the tube was attached to the end plate by an angle ring, and the same movement which caused the grooving, G, of the end also resulted in a groove, A, being formed in the bend of the angle iron.

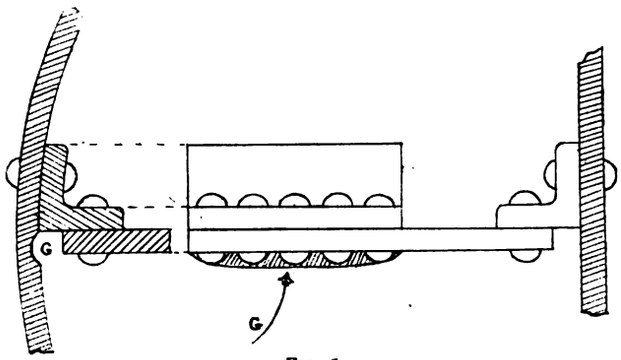

FIG. 1.

Fractures from overheating are also sometimes found in Lancashire boilers which have their boiler flues fitted with strengthening hoops or collapse rings, without water-spaces between the ring and the plate; a water-space of 1in. or more should always be allowed, to permit the water to come in contact with the plate at all parts. The water-spaces should be kept clear of deposit of all kinds, otherwise the benefit of the space would be lost. Side flues are occasionally met with too high at the top They should in no instance extend above the water-level in the boiler, as there is serious danger of overheating the plate. Amongst the defects which show after a boiler has been some time at work may be mentioned blisters or laminations in the plate. Blisters should be pared off down to the solid, and if of large proportions the plate should be patched or renewed.

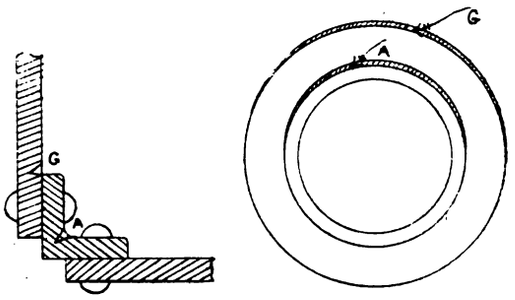

FIG. 2.

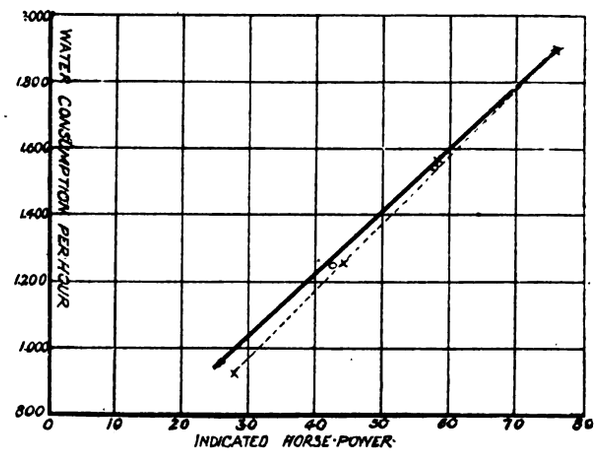
The most dangerous defect of all we meet with is external corrosion, principally at the seating walls, and it is good practice to keep all longitudinal seams entirely clear of the seating. Whenever any rust is seen about the seating, a thorough investigation should be made and the actual condition of the plates discovered. The stay-bolts that run through the boiler should be examined for flaws, and care should be taken that they are not too taut.

There are several smaller points of considerable importance about a boiler, one of which is that the bearers, which carry the firebars, must not be allowed to rest upon the sides of the furnace. They must rest upon supports riveted to the plates. This prevents the bearers cutting into the plates. The spindles of lever and deadweight valves are liable to get stuck fast where they pass through the cover of the valve, and all boiler fittings, such as gauge cocks, blow-off cocks, check valves, etc., should be thoroughly inspected before the boiler is passed ready for steam.—GEORGE EMENS, JUN.

Question No. 717.—A high-speed lighting set of 200 h.p. when working at full load requires 160lb. steam in steam-chest, but at three-quarter load only 120lb. is registered on the pressure gauge connected to it. The engine is controlled by throttle valve, and runs condensing. Which should be the most economical boiler pressure to use (as regards coal consumption) for continuous runs at three-quarter load—165lb. or 130lb., and why? Does superheating by 100deg. affect the case?

Best Answer to No. 717 (*awarded* 10*s.*).—If the engine be run on a steady three-quarter load, working the boiler at the higher or the lower pressure will make very little, if any, difference to the coal consumption. In the first case the steam will have to be raised to a pressure of 165lb. per square inch and be throttled down to 120lb. at the engine, while in the second case the steam is only raised to 130lb. and passed straight to the engine with practically no throttling. Experiments have been made to ascertain if there is any difference in economy between the two methods. The curves are the result of one made by Captain Sankey and published at the end of his paper on "Governing of Steam-Engines," read before the I.M.E., April, 1895. The circles and crosses plotted along the diagonal lines represent the experimental points, the full line represents the consumption when the boiler pressure itself was varied, and the dotted line the consumption when, the boiler pressure remaining constant, the steam was throttled, boiler pressure 120lb. The difference in consumption at the point where they are widest apart is only



about 1½ per cent., showing an economy in favour of the constant boiler pressure and throttling. If these curves are reduced to heat units per hour consumed instead of pounds of steam per hour, they will be found to practically coincide.

At first sight this coincidence appears rather strange, as the throttled steam is drier than the other owing to the heat generated by friction on its passing through the valve, which heat dries and perhaps superheats the steam. This dryness should reduce the cylinder condensation, and, therefore, the relative consumption, but the experiment shows otherwise. This can only be accounted for by the increased range of temperature in the cylinder and the slight loss owing to the transference of heat between the valve and the steam, the steam giving up heat on one side and the valve again giving heat at a lower temperature on the other.

A superheat of 100deg. F. would increase the economy of either method, but not influence their relative economy to any extent; perhaps the lower pressure would be more suitable in that case, owing to the slightly lower temperature (about 20deg. F.) to be dealt with in the steam-pipes. If the plant was run without the superheat, the higher pressure would be more more convenient, owing to the less liability of priming, and if the boiler delivered wet steam from any cause it would have less chance of damaging the engine.—E. J.

[Other replies to Question No. 717 will be given in our next issue.—ED. *E. E.*]

Supplement to "The Electrical Engineer,"
SEPTEMBER 30, 1904.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

730. I have a 5-h.p., 500-volt, shunt-wound motor whose behaviour is somewhat weird, for on starting up in the ordinary way with the usual type of shunt motor starter, the machine on "no load" starts on the second live contact of the starter, runs about 20 or 30 revolutions, and then, apparently remembering it is running the wrong way, stops, and reverses itself. All this happens before the starter is put on the third contact, and except for this curious behaviour at starting, it behaves like any ordinary motor. There is no sparking at the brushes, or abnormal current during this phenomenon. What causes it?—H. G.

ANSWERS.

Question No. 717.—A high-speed lighting set of 200 h.p. when working at full load requires 160lb. steam in steam-chest, but at three-quarter load only 120lb. is registered on the pressure gauge connected to it. The engine is controlled by throttle valve, and runs condensing. Which should be the most economical boiler pressure to use (as regards coal consumption) for continuous runs at three-quarter load—165lb. or 130lb., and why? Does superheating by 100deg. affect the case?

Answer to No. 717 (*awarded 7s. 6d.*).—In replying to this question it would perhaps be well to primarily examine the comparative efficiencies of working at the two pressures without superheating the steam directly. Resolving the investigation of the economy in coal consumption into two factors, we have first to consider the efficiency of steam generation at the boiler, and latterly the conveying and utilisation of the steam in the engine cylinder. From the figures immediately given it will be seen that a saving undoubtedly results from generating steam at the higher pressure—165lb. per square inch—the increment of heat applied being proportionately less than the greater energy derived from the increased pressure. Evaporation at 165lb. pressure requires but six heat units more than are needed to evaporate at 130lb. pressure. The relative value of steam at different pressures, used without expansion, varies as the pressure multiplied by the volume; therefore, the higher the pressure, the greater power is available. Assuming an evaporation of 10lb. of water per pound of coal, then at 165lb. pressure with a volume of 2·75 cubic feet per pound of steam:

$$10 \times 2\,75 \times 165 = 4{,}537.$$

At 130lb. steam pressure and a volume of 3·4 cubic feet per pound of steam

$$10 \times 3{\cdot}4 \times 130 = 4{,}420;$$

$$4{,}537 - 4{,}420 = 117 = 2\,6 \text{ per cent.}$$

Deducting the six heat units originally added to give the higher pressure, which are equivalent by the following figures to 0·5 per cent.: Total heat units at 130lb. pressure = 1,188; ditto at 165lb. pressure = 1,194.

$$1{,}194 - 1{,}188 = 6 = 0{\cdot}5 \text{ per cent.}$$

Subtracting 0 5 per cent. from 2 6 per cent., we are left with 2·1 per cent. more energy for the same expenditure of heat by generating at the higher pressure.

Any additional radiation losses, by reason of the higher temperature of steam at 165lb. pressure over that at 130lb., are negligible if the boiler plates exposed and steam-pipes are lagged with good insulating material. We may reasonably rely upon 2 per cent. more energy available at the boiler, but this energy represents some mechanical gain, and can only be realised as such in the engine.

Considering next the performance of the steam through the throttle valve to the cylinder (the cut-off, and therefore steam expansion, in the latter being constant), the throttle valve, operating as a reducing valve at three-quarter load, brings the boiler pressure (165lb.) down to 120lb. at the steam-chest. This, providing the steam is dry, results in a slight superheat; and if the steam be wet, the heat units liberated evaporate part or all of the moisture Taking the former case and assuming the specific heat of steam as ·48, then the eight heat units liberated, when pressure is reduced to 120lb., will give these results:

$$\frac{8}{\cdot 48} = 12{\cdot}5\text{deg. of superheat.}$$

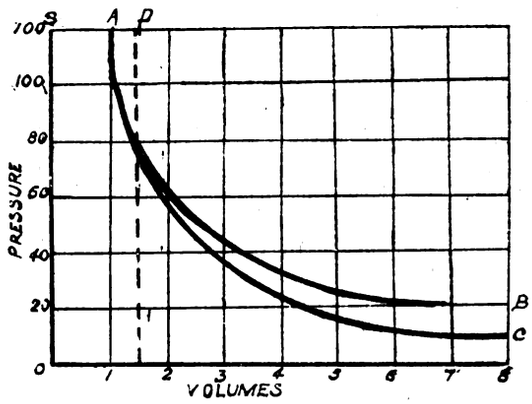
In the event of the steam possessing 2 per cent. moisture the aforementioned eight heat units will evaporate

$$\frac{8}{874} = {\cdot}009\text{lb. of water.}$$

(latent heat of steam at 120lb)

The wetness is, therefore, reduced ·02 − ·009 = ·011, or from 2 per cent. to 1·1 per cent.

There should be no need to herein emphasise the economy ensuing from the use of dry or superheated steam, but the expansion curves shown here may be of assistance to some. The main features of each curve are exaggerated, but they will serve to illustrate the argument. A C is the curve which would be drawn by the expansion of steam superheated or dried sufficiently to prevent initial condensation. The volume is therefore represented by S A. A B



is the expansion curve of saturated steam, its original volume being equal to S D, but due to initial condensation this volume is reduced to S A Some of the steam condensed is re-evaporated during expansion, hence $p \times v$ is greater at the point of exhaust than at the point of cut-off. The heat, however, used to re-evaporate is drawn from the cylinder walls, thus lowering the mean temperature of the cylinder and reducing the general efficiency. If steam had been generated at the lower pressure (130lb), this pressure being just sufficient to balance losses due to friction, etc., in the pipes, and to keep the engine running at its recognised speed, with three-quarter load, the throttle valve being full open, then this steam at the valve chest is considerably wet and will not act so efficiently in the cylinder, hence more steam is necessary. The heat units added at the boiler to increase the steam pressure make for economy, in so far that when either drying or superheating of the steam occurs by reason of throttling, these heat units are less than what would be necessary to generate steam at a lower pressure to compensate for the lower efficiency at the engine.

With the introduction of a superheater to give 100deg. superheat to the steam, the same principles as those already enunciated apply if the superheater and boiler be considered one plant. They should be reckoned as such if the one is built into the flues of the other. Economy will still accrue from generating at the higher pressure, but more because of side efficiencies, common to both conditions—with or without superheater—which will be dealt with later, rather than owing to drying of the steam at the

Digitized by Google

throttle valve. The extra heat units, instead of being used to increase pressure, would be more efficiently employed adding a few degrees more superheat at the superheater. To generate steam at 130lb. pressure would be more economical, provided superheat is added, if the extra heat units are applied directly to the superheater rather than used to raise pressure to 165lb at the boiler, but should those heat units be dissipated, or should the superheater be separately fired, these conditions would be reversed.

However, most engineers will prefer to generate at the higher pressure (163lb.) for the following reasons, other than thermal, all of which make for more efficient running of the entire plant, and therefore indirectly result in economy: (*a*) If steam pressure is arranged at the boiler for different loads, the governors would be less sensitive, having to move the throttle more for regulation; in fact, if governing were performed at the boiler by raising and lowering pressure to suit the load, the governors may be dispensed with, only under such circumstances. heaven help the firemen. (*b*) Auxiliary plant, such as feed pumps, which are steam driven and may work expansively, would be run more economically with the higher pressure. (*c*) A greater margin is available to permit of fluctuations of pressure and still keep a constant pressure at the valve chest to maintain the correct speed. It is for this reason most refuse destructors, when employed for steaming purposes, have a reducing valve introduced between them and the main battery of boilers, as a constant pressure cannot be relied upon, from refuse-fired steamers, due to the varied classes of refuse consumed. (*d*) A greater store of energy is retained in the boilers.—WALLSEND-ON-TYNE.

Answer to No. 717 (*awarded* 5*s.*).—It is only natural that the pressure in the steam-chest should be considerably lower at three-quarter than at full load, for adjustment of initial pressure to suit the load requirement is the principle upon which throttle governing is carried out. The formula for the mean effective pressure—viz.:

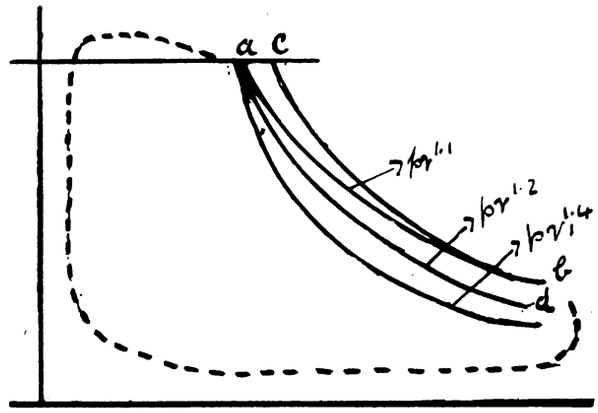
$$\text{M.E.P.} = p_i\left(\frac{1 + \log_e r}{r}\right) - p_b,$$

where p_i is the initial pressure and p_b the back pressure—distinctly shows this, for the other terms—r, the ratio of expanson, and p_b—are constants.

The initial pressure varies proportionately to the load, and at maximum the steam should not be throttled at all. Having the boiler pressure fixed, speaking generally, the weight of steam consumed per horse-power depends upon the number of expansions of steam that take place in the engine; in other words, upon the time of cut-off in the high-pressure cylinder, for the setting of the valves on the intermediate and low-pressure cylinders—the engine being assumed to be of the triple-expansion type—only determine the distribution of power between the three cylinders after the high-pressure valve has decided the power of all three combined. The most economical point of cut-off is by no means sharply defined; several in the same neighbourhood may give practically equally good efficiency. The extreme is reached when the work done by the steam as it expands just equals the loss due to piston friction, etc. In good practice the expansion is carried to within 4lb. or 5lb. per square inch of the condenser back pressure. But, in the engine considered, the valves are already set, so that the number of expansions is fixed also; the most suitable boiler pressure has to be decided upon. Now, the diameters of the cylinders, the cut off, and speed being fixed, a certain mean effective pressure must act on each of the pistons for a definite power to be developed. According to the particulars, 160lb. per square inch in the gauge steam pressure is required under the conditions to run at full load.

Clearly, then, if 200 h.p. is the maximum load, the boiler pressure must be 160lb. per square inch gauge + the drop in the steam mains—165lb. per square inch gauge will only just suffice. There will be no throttling at this load. Note.—This provides no margin for overload; in case of overload the speed will drop. It is evident the steam pressure must not be reduced. The steam, if dry on entering the throstle valve, is throttled when steaming on a load less than full. It is superheated slightly. At three-quarter load, from the pressures given, six British thermal units would be liberated, which would superheat the steam 12·5deg. F. Of course, this superheat would help to keep the steam dry during admission. With a considerable degree of superheat a reduction in steam pressure might be possible, not because of any thermodynamical reason, but on account of its beneficial effects in admitting the steam dry to the high-pressure cylinder, and possibly maintaining the dryness throughout expansion in that cylinder also. Any wetness reduces the heat units in the steam available for doing work, so that more steam has to be supplied. Condensation on the cooled cylinder walls adds to any original wetness, the degree being determined by the difference between temperatures of the steam upon admission and that of the walls. The point of cut-off, therefore, affects the wetness, for the later in the stroke it occurs, the higher will be the average pressure, and consequently the higher the mean temperature.

Since the heat exchange is directly proportional to the period of contact, the loss is smaller in high-speed engines. The steam becomes wetter as expansion proceeds, owing to molecular liquefaction due to the internal energy being expended in doing work. The wetness is a most serious source of loss, and leads to a great lessening of the useful heat extracted from all that taken from the furnace. The accompanying diagram gives an idea of the loss. In it are



shown four different curves, which represent the behaviour of the steam under different conditions; $a\,b$ is the saturated steam curve, assuming adiabatic expansion. It follows approximately the law $p\,v^{1\cdot1} = \text{constant}$; $a\,d$ is the hyperbola $p\,v^{1\cdot2} = \text{constant}$, and illustrates the action generally taking place under favourable circumstances, the steam being initially dry. Sometimes, however, the curve may fall away so far as to lie on the $p\,v^{1\cdot4} = \text{constant}$ curve. The last curve ($c\,b$) is the case in which the steam is originally superheated sufficiently to keep the steam dry up to release. It can be seen joining the saturation curve.

The object of superheating is to make the actual curve hug the saturation curve as nearly as possible. One per cent. of wetness in steam at 188lb. absolute would mean a decrease of 8·5 British thermal units in the total number available. Assume this percentage at cut-off. On the other hand, to have kept this steam dry would have required about 8deg. F. of superheat, or 3·8 British thermal units—that is, an extra expenditure of 3·8 units to avoid a loss of 8·5—obviously a wise course. Still greater gain would accrue from the use of a higher degree of superheat; 100deg. F. of superheat would be enough very probably to keep the steam dry in the high-pressure cylinder up to release. Superheating then would have the effect of improving the thermal efficiency, and therefore a less weight per unit power would be necessary. Even in this case, though, it would be advisable to use an earlier cut-off, and expand more fully if permissible. For three-quarter load, undoubtedly the most economical boiler pressure would be 130lb. per square inch, for, disregarding the question of whether any energy is lost at the throttle at the higher pressure, the increased radiation all over the pipe system at the higher temperature must cause extra loss. If three quarter load is regarded as top load, there would be no sense in using a so much higher boiler pressure than steam-chest pressure; but, as remarked before, if 200 h.p. is the full load, then, of course, one would have to have the reserve of pressure to meet demands.—T. H. H.

Answer to No. 717 (*awarded* 5*s.*).—Taking first the difference in the amount of heat required to generate steam at the two different pressures, we find from steam tables: total heat of 1lb. of steam at 145lb. per square inch absolute—*i.e.*, 130lb. per square inch by gauge—from water at 32deg. F. = 1,190 heat units, and for the same amount of steam at 180lb. per square inch absolute (165lb. per square inch by gauge) = 1,195 heat units, and as the total heat losses would be practically the same in each case, the extra heat required to produce steam at the higher pressure may be put down as ·4 per cent. Now, the benefit derived from the higher pressure of steam at the throttle valve is the improvement in the dryness of the steam, due to the reduction in pressure, being equivalent to supplying the cylinder with a greater quantity of dry steam. Assuming the dryness fraction of the steam on the boiler side of the throttle valve to be ·9, then the dryness fraction after reduction of pressure is obtained from the equation

$$S_1 + x_1 L_1 = S_2 + x_2 L_2,$$

where S is the sensible heat, L the latent heat, and x the dryness fraction of the steam; or, taking the temperature of the feed water as T_1, and the temperature of the steam as T_2, it is expressed more fully as follows:

$$(T_2 - T_1)_1 + x_1 \{966{\cdot}6 - {\cdot}7\,(T_2 - 212)\}_1 = (T_2 - T_1)_2 + x_2 \{966{\cdot}6 - {\cdot}7\,(T_2 - 212)\}_2.$$

Case I.—Steam at 145lb. per square inch absolute reduced to 135lb. per square inch absolute.

$$(355 - 32) + {\cdot}9\ \{966\,6 - {\cdot}7\,(355 - 212)\} = (350 - 32) + x\ \{966{\cdot}6 - {\cdot}7\,(350 - 212)\}$$
$$1{,}103 = 318 + 870\,x. \quad . \quad . \quad . \quad . \quad (1)$$

$\therefore$ x equals ·9203, being an increase in the dryness fraction of ·23 per cent.

Case II.—Steam at 180lb. per square inch absolute reduced to 135lb. per square inch absolute.

$$(370 - 32) + {\cdot}9\ \{966{\cdot}6 - {\cdot}7\,(370 - 212)\} = (350 - 32) + x\ \{966{\cdot}6 - 7\,(350 - 212)\}$$
$$1{,}108 = 318 + 870\,x \quad . \quad . \quad . \quad . \quad (2)$$
$$x = {\cdot}9080,$$

giving the increase in dryness as ·80 per cent., thus showing the increase in dryness from the higher pressure of steam to more than compensate for the extra heat required in raising it, and although the economy is not much, it is better to work with the drier steam, as it lessens the cylinder condensation trouble. This practice of generating steam at a higher pressure than required by the engine, and reducing down, is being largely followed. With reference to the question of superheating by 100deg., the total heat of the superheated steam is obtained by adding to the total heat of the saturated steam the amount of superheat multiplied by the specific heat of superheated steam, which is ·48.

Case III.—Case I. with 100deg. F. superheat. From (1) we have the total heat of saturated steam at 145lb. per square inch absolute = 1,103 heat units; therefore, with the addition of 100deg. superheat, the total heat becomes

$$1{,}103 + (48 \times 100) = 1{,}151 \text{ heat units},$$

this being equal to the total heat after reduction to 135lb. per square inch absolute.

$$1{,}151 = (350 - 32) + x\ \{966\,6 - {\cdot}7\,(350 - 212)\}$$
$$x = {\cdot}957,$$

increasing the dryness by 5·7 per cent.

Case IV.—Case II. with 100deg. F. superheat. From (2) we have the total heat of saturated steam at 180lb. per square inch absolute = 1,108 heat units, which when superheated 100deg. F. becomes

$$1{,}108 + (48 \times 100) = 1{,}156 \text{ heat units},$$

which is equal to the total heat after reduction, as before, to 135lb. per square inch absolute.

$$1{,}156 = (350 - 32) + x\ \{966{\cdot}6 - {\cdot}7\,(350 - 212)\}$$
$$x = {\cdot}963,$$

increasing the dryness by 6·3 per cent. The increase in the dryness of the steam by superheating 100deg. F. is thus shown to be more substantial in both cases, but as to whether the superheating would be more economical depends on the cost of providing the superheat, as in the case of superheaters placed in the flue there is a loss of draught due to reduction of temperature in the gases, and with separately fired ones there is fuel and attendance as well as cost and maintenance in both cases.—E. L.

Question No. 719.—In an alternating-current plant with rotaries a bad phase was made when synchronising another alternator with one previously running, and which caused all the rotaries to lose their fields. The same thing has happened when a bad phase has been made in synchronising a rotary. Could anyone explain in full detail exactly what happens to the rotary as to how it loses its field?

Answer to No. 719 (*awarded* 7*s.* 6*d.*).—The cause of the trouble is the change in 'bus-bar voltage as a result of the bad parallelling. When the fresh alternator is switched on to the 'bus bars with its voltage out of phase with the 'bus-bar voltage, a large idle or synchronising current flows between the 'bus bar and the incoming alternator armature. This current may be either a lagging or a leading one with regard to the 'bus-bar voltage, according to the relative phases at the instant of switching in. Thus, in Fig. 1

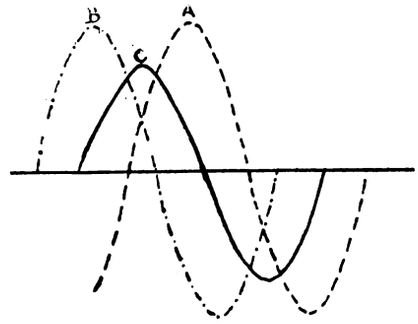

FIG. 1.

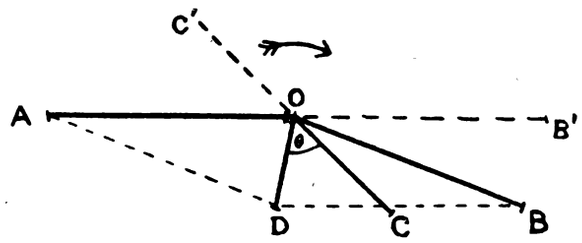
A and B represent the voltage curves of the incoming alternator and the 'bus bars respectively, and they are shown with A lagging considerably less than the correct half-period behind B. Curve C is the algebraical sum of A and B at each instant, and shows the net resultant voltage tending to pass the synchronising current between the 'bus bars and the incoming alternator. This net voltage, and consequently the synchronising current, lags with regard to the 'bus-bar voltage, B, but if B had been the incoming voltage and A the 'bus-bar voltage, the synchronising current would be a leading one relatively to the 'bus-bar voltage. Either case is liable to produce the effects mentioned. If it is a lagging current there will be a sudden fall in 'bus-bar voltage, whilst if a leading current the 'bus-bar voltage will rise, due to the demagnetising armature reaction of a lagging current and the magnetising reaction of a leading current respectively.

Now, when a synchronous alternating machine, such as a synchronous motor or a rotary converter, is subjected to changes of terminal voltage, the necessary balance between terminal voltage and internal back voltage is preserved, not by change of speed, as in a direct-current motor, but by changes in armature reaction. If the terminal volts drop, a leading current (lagging with regard to the internal back voltage) is immediately drawn from the mains and automatically weakens the field magnets of the rotary and reduces the back voltage to the required extent. The reverse occurs if the terminal volts rise. The amount of armature current taken to compensate for a given change in terminal voltage varies considerably with the design of the rotary, but a change of 10 per cent. in the terminal voltage might in some machines increase the input current of the rotary some 30 or 40 per cent. The current would *increase* whether the voltage charge were up or down, only in the former case the current would be a lagging one and in the latter a leading one. Supposing the rotaries to be already working at their full load, such an increase (or the still greater increase which would result from a greater voltage change than 10 per cent) would open the automatic cut-outs on all of them. This is apparently what happened in the cases mentioned both with the badly-paralleled alternator and, which is practically the same thing, with the badly-paralleled rotary converter. It is incorrect to speak of the occurrence as a case of loss of field,

Digitized by Google

as a rotary cannot lose its field so long as it remains connected to the alternating mains, the direct-currrent voltage (which is also the shunt voltage) simply varying up or down in accordance with the alternating voltage.—Q.

Answer to No. 719 (*awarded* 7*s.* 6*d.*).—To answer this question we must find what effect a "bad phase" has on the circuit. Let O A represent the voltage of an alternator, A, already under load and with which another machine, B, is to be synchronised. Now, B's switch should be closed when the phase of B's voltage is at O B'—*i.e.*, opposed to O A—so that little or no synchronising current flows. Instead, however, a bad phase is made and B connected to A when B's phase is at O B. The resultant voltage acting through A and B is equal to O D The resulting current, O C (equal to O D ÷ joint impedance of armatures), lags by a large angle θ behind O D. Now, O C has nearly the same direction as O B, while it is nearly opposed to O A—*i.e.*, machine B is retarded while A is accelerated. Consequently the angle A O B increases to 180deg., when O D and O C become zero. But A is now running above normal speed and B below, so that the machines overshoot the mark, and a current, O C', now flows,



tending to again restore A O B to a straight line. This swinging or "hunting" continues (with a period dependent upon the inertia of moving parts, and impedance of armatures) for some minutes, it may be, but, in the absence of any regular disturbing force, gradually dies down to zero. The effect upon the distant rotaries, however, may be most marked, as may be seen. Every surge of the generators produces a fluctuation in magnitude and phase of the alternating voltage impressed on the line. This disturbs the rotaries, and they endeavour to follow these changes, and set up a see-sawing action amongst themselves, and between themselves and the generators. The effect is aggravated if the natural time of swing of the rotary armatures (determined by their inertia and impedance of the circuit) happens to be near to or a multiple of that of the generators. Under these circumstances, the effect may be so large as to swing a rotary clean out of phase, and cause it (if by that time the alternate-current cut-outs have not acted) to drop into phase again either with the same or a reversed polarity on its direct-current brushes. If the armature falls back a distance corresponding to an even number of poles, the polarity will be the same, and the field which had temporarily disappeared will rebuild in the same direction, but if an odd number of poles, the polarity will be reversed, and will reverse the field current. With several rotaries in parallel, probably all the direct-current breakers will open, and, if the fields are supplied from the 'bus bars cut them off, leaving the machines running with no fields. With the fields excited from the brushes, however, each rotary after such a disturbance will settle down with one or the other polarity, and the field build up again. In any case the field is temporarily or permanently lost. It is, of course, probable that flashing over will also take place at the commutator during the upset, especially with high-frequency machines.

Conditions vary so much with different plants that it is not always possible to say precisely in full detail the order of events, but the above describes what was the probable train of causes leading to what "F. B." observed.—R. C.

Question No. 720.—In a certain type of coking stoker the bars are subjected at the back end to a very intense heat and soon burn away, resulting very often in serious damage to the stoker, due to them falling. The bars supplied by the makers are of a low-grade cast iron. What should be the composition of the iron in order, as far as possible, to resist the intense heat?

Answer to No. 720 (*awarded* 7*s.* 6*d.*).—It is more than probable that the trouble is not due to the bars being made of any particular brand of cast iron, but is caused by other conditions, which we will consider in detail. The coal may be unsuitable; some coals require the furnace to be cleaned out very often, and when the boiler is fully employed the firebars are apt to become caked up with clinker and so get burned. There may also be inattention on the part of the attendant; many boiler troubles, at first unexplainable, are afterwards traced back to the personal equation. Some mechanical stokers have an intermittent instead of a constant supply to the furnace. When the coal is fed at intervals there is a tendency, particularly with certain brands of coal, to accumulate in heaps and prevent the passage of air between the bars. Another reason may be that there is not sufficient space between the bars for the particular coal used; in a somewhat similar case an increase of $\frac{1}{8}$in. effected a considerable improvement. Any increase made in the space between the bars must depend on circumstances, as too great a space may make matters worse. The bars should have end-play in the proportion of about $\frac{1}{2}$in. to the foot. Bars sometimes burn out through the upper surface of the grate being uneven—that is, should one bar be raised much above its fellows, that bar will stand a much greater chance of being fused. As a last resource wrought-iron bars might be tried; these stand a much higher temperature than cast-iron bars before melting, but would be considerably more expensive. Speaking from experience, the writer has never known firebars burn out except from the causes enumerated above. It is very doubtful whether an alteration in the brand of iron would mend matters; the remedy will almost certainly be found in another direction.—M. M.

Answer to No. 720 (*awarded* 7*s.* 6*d.*).—In this question it appears to the writer that the matter is not so much one of the firebars being of poor quality iron as the treatment to which they are subjected. The writer has experienced exactly similar troubles as those mentioned in the question, and found the causes to be as follows: Poor quality coal will require to be forced in order to keep up steam on heavy loads, and in forcing it it will melt and stick to the bars. This keeps the air from getting up between the bars to keep them cool, and the clinker fuses on to the bars and has to be kept free by the frequent use of the slicer. This separates the clinker, which takes the fused part of the bar along with it. The writer has seen new bars put into fireboxes, and the next time they have been examined (in about eight weeks) they have been burnt away so much as to be useless. By using a better quality coal, or by putting another boiler into service during heavy loads, so that the poor quality coal can be burnt without forcing, the trouble of burnt firebars has disappeared.

Another point with regards to the bars dropping down is in the way they are held. The bar ends generally work over a sill-plate, but ought not to rest on it, a bearer bar being fixed about 6in. further under the bars to support them. Sometimes through bad erecting this bearer bar will be too low, and consequently the bars will rest on the sill-plate, and when they get burnt short will drop on to the bearer bar and probably cause trouble. Boilers in which this defect has occurred, and which otherwise might have been kept in service much longer, have had to be shut down until new bars could be put in. If, however, the bearer bar is the right height, the firebars, although burnt short, will not drop and catch against the sill-plate, and the worst thing that will happen will be a small quantity of fire will continually be dropping out.

It is the writer's opinion that it is more economical to burn a better grade coal, with all its attendant advantages of better steam pressure, less forcing of fires, and less work for the stokers, and smaller repairs, than to burn a poor coal and firebars and have a heavy bill for renewals.—H. B.

[Other replies to Question No. 720 will be given in our next issue.—Ed. *E. E.*]

QUESTIONS AND ANSWERS.

thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

QUESTIONS.

731. How would you measure the self-induction of an alternator's armature?—E. V. C.

732. What is the best method of predetermining the voltage drop due to magnetic leakage in a transformer at, say, full load and any given power factor?—R. S. L.

ANSWERS.

Question No. 720.—In a certain type of coking stoker the bars are subjected at the back end to a very intense heat and soon burn away, resulting very often in serious damage to the stoker, due to them falling. The bars supplied by the makers are of a low-grade cast iron. What should be the composition of the iron in order, as far as possible, to resist the intense heat?

Answer to No. 720 (*awarded 7s. 6d.*).—A good cast iron for stoker bars should contain as great a percentage of iron (pure) as is practicable to procure a sound casting. It should contain as little sulphur as possible, not more than 2 5 per cent. of silicon, and not more than 1 per cent. of phosphorus. It is extremely difficult, and to some extent impracticable, to lay down any hard-and-fast chemical specification; the cost, if such a specification were adhered to, would be prohibitive. The old-time "trial by error" system has evolved, for each foundry or engineer, a bar which is suitable, and thus so many mixtures, each of them in the hands of a particular founder, can be cited as successful. A mixture which has been used for some 10 years in making bars for a well-known type of mechanical stoker is made up as follows: one part of hard iron, preferably old firebars; one part of pig iron, Scotch No. 1; three parts selected scrap iron. The above is a typical founder's mixture, and it is a matter of considerable discretion as to the selection of the scrap. No trouble has been, however, experienced, and a good sound uniform casting has almost invariably obtained. The personal element thus must enter into the question, but care and experience lessen the chance of failure.

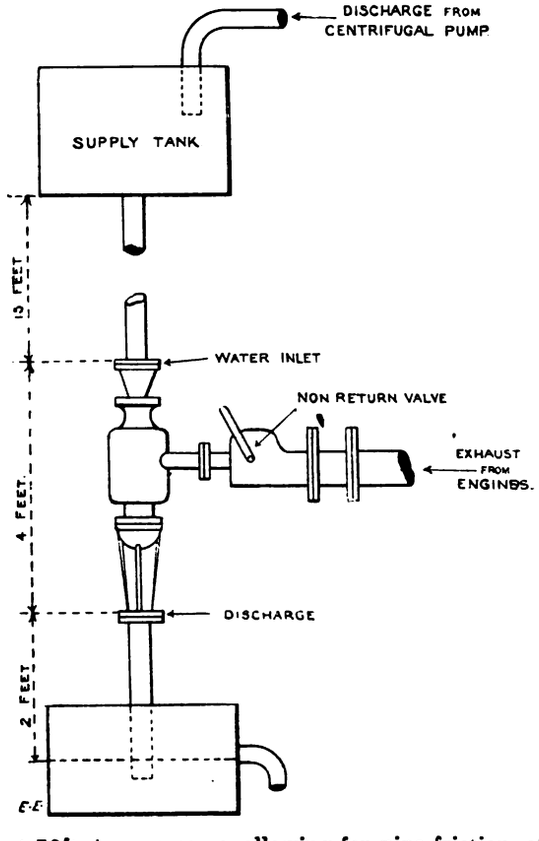
It must be said here that steam jets are used under the ends of the bars to keep them cool, and it may be that the propounder of this question has not availed himself of this method of prolonging the life of his bars. It is contended that jets are wasteful and a source of loss; they may be if not carefully used. All that is needed is a thin film of steam rising up under the ends of the bars, and the consumption need not, and should not, be more than of the order of ·1 per cent. of the steam raised. It is a simple matter to run a couple of ¼in. pipes along the side of the furnace under the bars connected by a cross pipe under the far end of the bars. The cross pipe need be only ¾in. diameter, and should have a number of small holes about $\frac{1}{32}$in. diameter drilled so that the steam may escape in a film and the draught carry it through the ends of the bars. Several firms advertise fireproof bars which they claim have a life many times that of the ordinary bars, but the composition of these is of a necessity a trade secret.—S E. T.

Answer to No. 720 (*awarded* 5*s.*).—The question as to the composition of the iron for the firebars of coking stokers, of the moving grate type, is not of such importance to the engineer as the proper working of the bars. If the writer of the question sees that his bars have a slight fall towards his back, say, of 3in., and a more efficient supply of steam jets to the back end of his firebars, he may get over the difficulty of his ends burning off. This has been the writer's experience for the last five years, having experienced the same difficulty when first starting the plant. He must also see that his bars have their full travel. Overhauling the stoking gear occasionally is conducive to economy.—J. C.

Question No. 721.—An ejector condenser coupled close to the exhaust range and about 2ft. below, supplied with water from a centrifugal pump at a pressure of over 20lb. per square inch, will not, either in a vertical or horizontal position, give more than 20in. of vacuum. Explain the reason for this.

Best Answer to No. 721 (*awarded* 10*s.*).—"E. L." does not give information enough to enable the peculiar defect, if any, in the ejector condenser, or its arrangement, to be determined. It is possible to maintain at least a 24in. vacuum with the type of condenser under consideration, and with enough cold water at the pressure mentioned that vacuum should be easily kept.

In the appended sketch, an arrangement of an ejector condenser plant which has been in daily use for some two years is shown. It deals with the steam from three 70-b.h.p. engines, and maintains a 24in. vacuum when all the engines are running at full load. About 4,000lb. of steam are used per hour by the engines, and the condenser is rated to pass 10,560 gallons of water (condensing) per hour. The centrifugal pump raises the water into a tank, the bottom of which is some 15ft. above the water inlet of the condenser; the condenser is 4ft. long, and the discharge pipe is 2ft. long. The difference of level between the supply and the discharge is thus some 21ft. The pump has a head



of about 30ft. to overcome, allowing for pipe friction, etc., and the power necessary is

$$\frac{105{,}600 \times 30}{33{,}000 \times 60} = 1{\cdot}6.$$

Allowing 40 per cent. pump efficiency, 4 b.h.p. would suffice for driving the centrifugal pump, and in the above case a 5-b.h.p. motor is more than ample for the work. The tank is interposed between the pump and the condenser, so that any air sucked in at the pump glands and pipe joints may be prevented from entering the condenser, as it is found to materially affect the vacuum.

The ejector should be fixed vertically—*i.e.*, the water inlet and discharge should be vertical, and the flow also; a minimum of 15ft. should be allowed as head at the condenser water inlet, and a clear discharge of 2ft. should be allowed below the discharge flange. Where practicable, a tank should be interposed between pump and condenser, and the discharge pipe should be water sealed. If these details be followed, and an allowance of 26lb. of water at 60deg. F. per pound of steam made, a 24in. vacuum should be readily obtainable. Of course, the pipes—*i.e.*,

Digitized by Google

exhaust, water inlet and outlet pipes—must be of ample size.—S. E. T.

Answer to No. 721 (*awarded* 7*s.* 6*d.*).—It certainly seems strange that the condenser will not give more than 20in. of vacuum with an equivalent head of water of 46ft. In order to find what has become of the other 4in. or 5in., the following tests should be carried out. As a preliminary trial, the valve between the condenser and the exhaust range should be closed and the condenser started by opening the air-cock and turning on the water. The air-cock should then be closed and the vacuum in the condenser noted. It will probably rise to 29in. of mercury. If it does not rise above 28in., the fault must be looked for in the condenser itself. First of all, see that all joints are tight, and also that the water inlet is free from obstruction. Also notice whether there are air bubbles in the water, as these would, of course, partially destroy the vacuum. If the fault is not discovered in the condenser, attention should be turned to the pipework. This is the most likely place, and all joints should be carefully examined for leaks. If practicable, the pipes might be tested with steam up to 50lb. per square inch; this will show up any leaks at once. If bubbles are found in the discharge water when the engines are working they indicate a leak somewhere, providing no bubbles came through when testing the condenser by itself. Should these tests not discover the fault, it would seem as though the condenser had too much work to do. It may be taken as a rough approximation that 550 gallons per hour will be required for every 10 h.p., and other sizes proportionately. With the figures given a 25in. vacuum should be maintained, provided that the condensing water is below 60deg. F. Unfortunately, "E. L." does not say what size condenser or what weight of steam he is dealing with, as if he did it would be possible to speak more definitely as to the probable cause of his trouble.—H. C. H.

Answer to No. 721 (*awarded* 7*s.* 6*d.*).—One of the points often overlooked by engineers when installing condensers of the ejector or similar types, is the supply of water to the condenser free from air, and, from the particulars given by "E L.," I should say this is the cause of the trouble in his case. If the water supply comes from a river, or a running stream of any description, or even from the town mains, there will be a certain amount of air in the water before it enters the pump suction pipe; and with a very small leakage in the suction pipe a considerable amount of air will be drawn into the pipe. If "E. L." has not examined the suction-pipe joints already, I should advise him to do so, and he might find an increase in his vacuum right away. However, a perfect suction pipe will not get rid of all the air in the water, but there are several ways by which this air can be got rid of. A tank could be placed just below the pump, as near to it as possible, and the suction for the pump taken from this tank. This would allow the water in the tank to deliver up the air. The suction pipe would have to be as short and have as few joints as possible, or things might soon be as bad as before if one of the joints happened to leak. This method, however, is impracticable in a lot of cases and also expensive, as it involves the cost of a tank, and possibly of another pump to fill it.

Another way would be to place the tank high enough above the condenser to get the requisite pressure, and use the pump for filling the tank. This method also has the same objections as the last method. A way by which I have known the same difficulty to be overcome, and the cost of which is trifling, is as follows: An air-vessel, which should have an opening about equal to the diameter of the pipe to offer a fairly large surface to the water, is placed on the pipe between the pump and the condenser; a small pipe, say about 1in. gas-barrel, is screwed into the top of the air-vessel, and taken up high enough to stop the water running over the top, which is left open; it would have to be about 45ft. in "E. L.'s" case. It will be found that the air will escape by the pipe. An automatic valve could be placed on the air-vessel instead of the air-pipe, so arranged that when the water in the vessel got below a certain level, a cock at the top of the vessel would open to let out the air; only as the cost of this apparatus would be more than an air-pipe, and its action is not as certain, it cannot be considered such a good arrangement.—J. B. R.

Answer to No. 721 (*awarded* 5*s.*).—There are many reasons to account for the vacuum being as low as 20in. in the case mentioned. In the first place, is the condenser big enough for its work? Is the water supply sufficient in quantity and low enough in temperature? Water used over and over again from a cooling pond will be liable to get very warm as the day progresses, and this will easily keep the vacuum low. If this is the cause of the trouble, the vacuum will be higher when starting up for the day, and will gradually drop as the water in the pond becomes heated up. Better cooling facilities are, of course, the remedy for this fault. Are there any leaky glands on the engine, or leaky joints between the engine and exhaust range and condenser, these should be examined, and any leaky glands or joints repacked or remade. A very slight amount of air drawn in this way will make a very great fall in the vacuum. If possible, have the condenser outlet pipe discharging below the level of a small well. Any air brought in through leaky glands or joints, or entrained in the water, can at once be detected, as the air bubbles will, of course, rise to the surface of the well. The centrifugal pump may be drawing air either at the shaft glands or at a joint in the suction pipe. If the pump is not drowned, this will be found out by observing the amount of energy necessary to drive the pump. If this is at all excessive, the pump should be overhauled at once, as air introduced in this way tends to break the column of water supplied to the condenser, and as it is essential for the best working that the water be supplied in a steady, unbroken column, it is obvious that the vacuum will suffer badly. Any of the above defects will keep the vacuum down, and should be sought for and remedied at once, as 20in. is very poor for the type of condenser mentioned, the writer being able to keep 27in. on a constant all-day full load with a head of 12ft. to 15ft. and a constant supply of water from a river. The amount of head in this case is quite ample, and could be reduced with resulting economy, provided that the condenser or its connections are kept in a proper condition.—W. T. W.

Answer to No. 721 (*awarded* 5*s.*).—It is possible, though perhaps hardly probable, that the condenser put in is not of sufficient capacity to deal with the load of the engine. If the condenser *is* large enough, there are several things which would prevent its maintaining a proper vacuum. Unless the joints in the exhaust range and connections to condenser are well fitted, air leaks through and impairs the vacuum. Another reason may be that the piping for the delivery of condensing water is too small or has become partially choked by sediment, or possibly small stones which have been carried over with the water; this also applies to the condenser itself and exhaust piping. If the condensing water is used over and over again, being circulated through some cooling apparatus, it is possible that the water may become fairly hot, necessitating a bigger supply than the condenser can deal with. The question states that water is delivered at 20lb. per square inch. Is this pressure at the pump or at the condenser? If at the former, and the condenser is connected by a long length of piping having several bends in it, the pressure at the condenser is considerably lowered, and the quantity of water diminished, and not a sufficient supply kept up. The steam valves of the engine should also be examined to see if any leakage takes place, as this causes a considerable amount of extra steam to the condenser, which would prevent it maintaining the vacuum. As it is rather unusual for ejector condensers to get out of order when properly erected, on account of their simplicity of working, it would be as well to check the vacuum gauge. No advantage, in the writer's opinion, is gained by running the condensers horizontally.—ERG.

Question No. 722.—Describe the best methods of plating carbon brushes with copper or nickel, having regard to the fact that carbon is porous and absorbs the electrolyte.

Answer to No. 722 (*awarded* 7*s.* 6*d.*).—The only real difficulty attending the electroplating of carbon brushes is that arising from the absorption of the electrolyte by the carbon. During the drying of the brushes, after the plating is completed, the absorbed salts crystallise out,

Digitized by Google

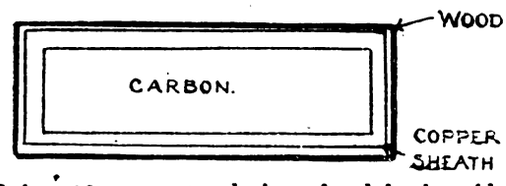
corroding the plating, and fouling the portion of the brush left bare. This will go on for a considerable time, and it is almost impossible to remove the absorbed salts by washing. The problem arises how to prevent the absorption. This might be accomplished by coating the carbon with a thin, acid-proof, non-absorbent material, such as paraffin wax dissolved in benzine; but this means that the metal plating would be more or less insulated from the carbon, and the beneficial object of plating impaired. The best method known to the writer is to soak the brushes in distilled water for a few days until they become saturated, after which they should be instantly placed in the electrolytic bath with the current connected, so that the deposition commences the moment the brushes touch the electrolyte. Even then a little of the electrolyte will be absorbed by diffusion, but not sufficient to cause any trouble. At the commencement, the brushes should be immersed $\frac{1}{8}$in deeper than their normal position, until a thin coating of metal has been deposited. By then raising them to normal position the carbon is brought out of contact with the electrolyte.

The following solutions will be found very suitable: For copper plating—to a quantity of distilled water, representing the bulk of the electrolyte to be used (which bulk will depend on the number of brushes to be coated at one time and the size of the tank), add crystals of cupric sulphate gradually, and with constant stirring until the solution attains a gravity of 10deg. Beaumé, or 1 075 specific gravity. Then add, with constant stirring, pure sulphuric acid until the specific gravity rises to 1 083. Filter the solution. Use clean pure copper anodes suspended on each side of the cathode brushes, the total working surface of anodes to be equal to total brush cathode surface. A current density of 10 amperes per square foot will be found suitable. On removing the brushes wash well in distilled water. Dry in hot sawdust or in water-oven. Polish gently with a steel burnisher.

For nickel plating it is best to first cover the brushes with a film of copper. Prepare the nickel electrolyte as follows: for every 10 litres of electrolyte required, according to the size of tank used, dissolve 135 grm. of pure nickel in weak sulphuric acid (one of acid to two of distilled water by weight), and heat until completely dissolved; add some distilled water and neutralise the liquor with ammonia. Filter the solution. In another vessel dissolve in distilled water 70 grm. of carbonate of ammonia, and add, with care and constant stirring, sulphuric acid until the solution becomes neutral. Filter the solution. Mix the sulphate of ammonia thus obtained in the second vessel with the sulphate of nickel made in the first vessel, and add cold distilled water to make 10 litres. Use pure nickel anodes having a total working surface equal to total brush cathode surface. A current density of 10 amperes per square foot of cathode surface will be right until a film of deposited nickel is obtained, then raise the brushes $\frac{1}{8}$in. (as in the case of coppering brushes) and reduce to five amperes per square foot. On removing wash the carbon brushes in cold water, and dry in hot sawdust. If required to polish the deposited nickel, it must first be cleaned by means of rapidly revolving brushes. An ordinary circular pig-hair brush sprinkled with soft chalk is first used, and a vigorous scrubbing given; then felt discs and finely pulverised chalk or hard red is used, and finally a disc of wool, which gives a shining brightness.—G. W.

Answer to No. 722 (*awarded* 7*s.* 6*d.*).—The first thing to do is to make the carbon brush waterproof. This is done by dipping the part intended to receive the coating of metal in hot paraffin wax. It is now necessary to remove the excess of wax, and to improve the conducting property of this part of the carbon. This is done by brushing it with a very stiff brush made of fine wire, and rubbing in the finest plumbago. Another method is to dip the carbon, after removing the excess of wax, in a solution of phosphorus dissolved in bisulphide of carbon; while still moist dip the carbon into a bath of sulphate of copper or nickel. It now becomes coated with an almost invisible film of metal, owing to the phosphorus acting upon the metal in the bath, and depositing it in a metallic form. The coating can now be deposited upon the carbon by either of the two following solutions: the two mentioned are the easiest and simplest, though there are many others as good. Get a sheet of copper and press it into the shape of the brush, making it so that the carbon can be easily suspended by means of a clip inside, leaving, say, $\frac{1}{2}$in. space all round; make the copper the anode by attaching the positive lead thereto, and the carbon the cathode. The carbon should be as central as possible, so that an equal deposit all round can be obtained. The carbon is suspended by a clip; one bought at a stationer's answers the purpose excellently. The electrolyte is dilute sulphuric acid, and the current quarter of an ampere per square inch.

The above remarks apply to nickel plating, though greater care is required. The anode (nickel) should be shaped as in the diagram. Some nickel should first be



dissolved in a 10 per cent. solution of sulphuric acid, and then neutralised with ammonia until there is no action either on red or blue litmus paper; the bath should frequently be tested so as to keep it right. As the nickel is deposited the bath becomes acid; then, if ammonia be added to make it neutral again, you may find a few minutes later the bath is decidedly alkaline. The current strength should be somewhat stronger at first than subsequently, but it must not be so intense that the metal becomes burnt (when too high a current density is used the deposit becomes grey in colour and pulverulent, and is said to be burnt).—C. A. B.

Answer to No. 722 (*awarded* 5*s.*).—The following method is one which I devised some time ago for plating carbon, and the results which I have obtained are entirely satisfactory. The objection caused by the soaking up of the electrolyte has been avoided to a great extent by securing a rapid deposit, and this has also its industrial advantage of lowering the time requisite to produce an adherent

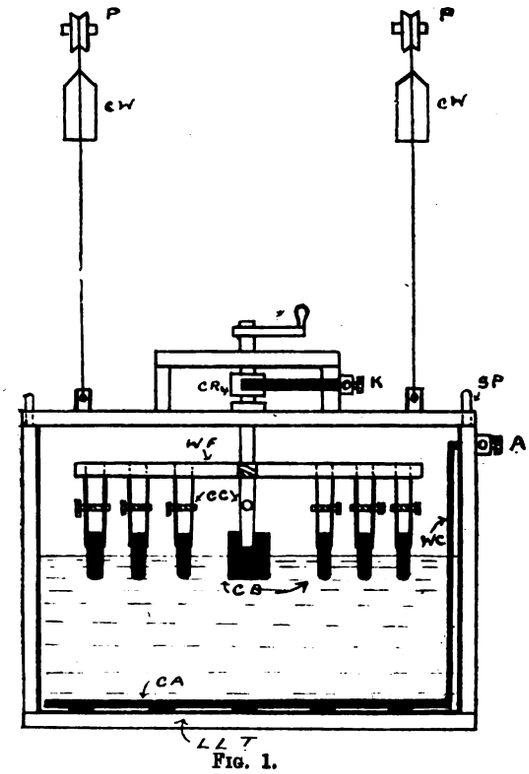


FIG. 1.

deposit. The effective operation in connection with this process is the rotation of the cathode (in this case the carbon brushes) which admits of a high current density being used, at the same time producing an adherent and uniform deposit of the metal. This rotation of the cathode causes the liberated gas to be thrown off from the surface, and, owing to the "skin" friction of the electrolyte, a very uniform deposit of copper is obtained.

Digitized by Google

Fig. 1 illustrates an apparatus suitable for plating carbon brushes. L L.T. is a lead-lined wooden tank; C.A., copper anode, insulated from lead lining by means of glass strips, shown black; W.C, wire connection from copper anode to terminal A, insulated from electrolyte by enclosing in a glass tube; C.B., carbon brushes; C.C., clamps for carbon brushes; W.F., wooden frame, consisting of four radial arms, to which clamps are fixed; C.R., contact ring, which revolves in contact with a metal brush and forms a metallic connection between the cathode and the terminal K; P P., pulleys over which wire ropes pass and enable the frame to be raised in order to insert and remove carbon brushes; C.W., counterweight; S.P., steady pin for securing frame during rotation of cathode. Having placed the carbon brushes in position in the clamps, the frame is lowered, so that the area to be deposited upon is below the surface of the electrolyte; the frame is then rotated at a speed just insufficient to cause splashing, and the current switched on.

The following points should be noted: (*a*) the operation of lowering and rotating the frame and switching on the current should be performed as quickly as possible; (*b*) the cathode must be rotated continuously whilst the current is flowing, and only allowed to remain stationary after the current has been switched off. The actual time required to obtain the deposit is about two minutes at a current density of about 400 amperes per square foot of cathode surface. After removal from the plating frame, the plated portions of the brushes should be well rinsed in hot and cold water, and then the whole allowed to dry in a hot sawdust bath. When the drying is completed, the plated portions should be polished up by means of a calico mop treated with rouge; the metallic surface then presented should be brilliant and adherent. If the carbon brushes have been handled much before plating, they should be brushed over with an ordinary "blacklead" brush. Either of the following electrolytes will be found satisfactory:

(*a*) Copper sulphate, 20 parts; water, 100.

(*b*) Copper sulphate, 12 parts; sulphuric acid, 23; water, 64.

This method is equally well adapted to nickel-plating, the only difference being the substitution of a nickeling solution and nickel anode in place of the copper. A little practice enables this whole operation to be performed very rapidly, as no appreciable time is lost in waiting for the deposition to take place, as is occasioned when the cathode is stationary.—S.

Question No. 723.—The poles of a shunt-wound direct-current machine (bipolar) are found to be reversed after dealing with a heavy short, the current probably amounting to 350 amperes, the normal full load of the machine being 180 amperes. Can any reason be given for this?

Answer to No. 723 (*awarded* 7*s.* 6*d.*).—The polarity of the field magnets of any shunt-wound self-exciting dynamo is not a fixed property of the machine, as it is easily reversed under certain conditions. By referring to Figs. 1A and 1B it will be seen that the connections are

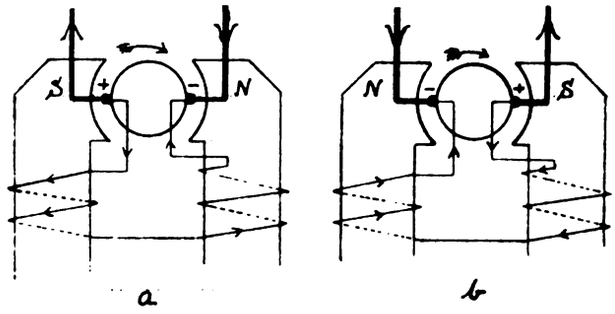

FIG. 1

unaltered by a change in the polarity of magnets, as a corresponding change takes place in the sign of the brushes. It is sometimes found necessary to separately excite from an external source the field magnets of a dynamo on test for the first time before it will excite itself; this is due to no residual magnetism existing in one of the magnets towards north polarity in excess of that in the other.

The output characteristic curve of a shunt-wound dynamo takes the form of that shown in Fig. 2. This curve shows that the voltage drops very gradually until a certain point is reached (usually about double or treble load), when it suddenly falls away to zero. This is due to the external resistance of the circuit becoming so small as to allow only a very low current to pass through the shunt coils, since the two circuits (external and shunt) are in parallel and the resistance of the latter remains constant while the former decreases. Consequently, at the point on the curve where the voltage drops away the field magnetism is very unstable, and it is under these conditions that the demagnetising field of the armature is at its maximum, as shown later.

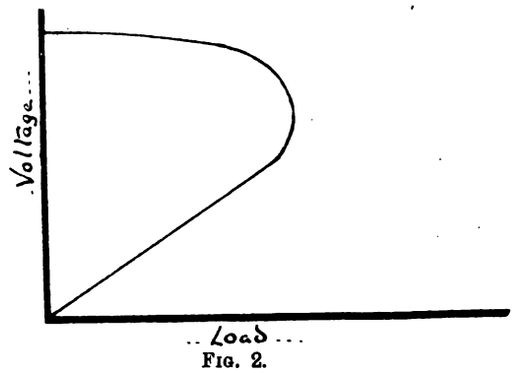

FIG. 2.

Fig. 3 diagrammatically shows a cross-section of a bipolar armature and field coils, the direction of the flow of the current in each case being by the symbols O and (×). The former indicates that the current is flowing towards the reader and in the opposite direction for the latter. The brushes are shown in the normal position with an angle of lead equal to ϕ, this lead being required to allow for the distorting effect of the armature demagnetising field. By careful study of the direction of the currents in the armature conductors, lying between the lines A and B, and also in the shunt coils, it will be seen that the field produced by these armature coils is in direct opposition to that of the shunt coils. As this demagnetising field (usually termed "armature reaction") increases with the load, it will be very strong when a dynamo becomes short-circuited, especially as the field produced by the shunt coils is in a very unstable condition under these circumstances, as stated previously when considering the curve in Fig. 2.

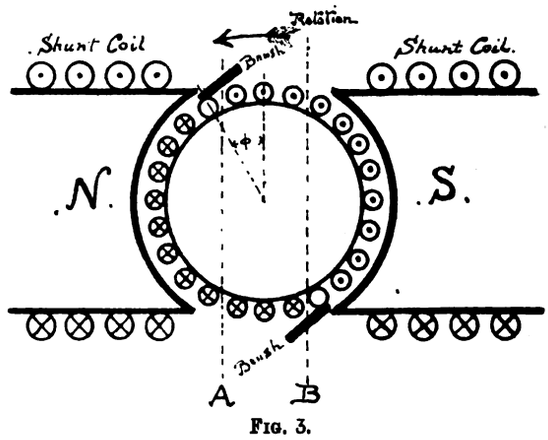

FIG. 3.

On a bad short-circuit and with inferior iron in the field magnets, the polarity of the machine is quite likely to be reversed by the field of the armature overpowering that of the shunt coils. Consequently, on removing the short-circuit and starting the machine up again, it will be found that the latter will re-excite itself in the reverse polarity due to the original residual magnetism being wiped out and replaced by residual magnetism of the opposite polarity.—P.

[Other replies to Question No. 723 will be given in our next issue.—ED. *E. E.*]

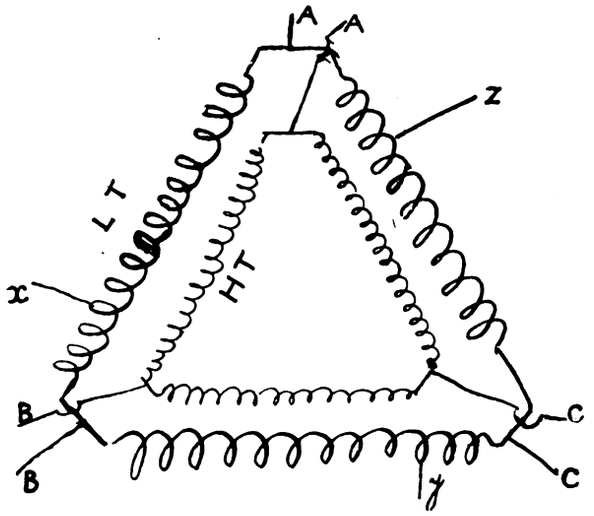
QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

QUESTIONS.

733. In a three-phase sub-station for rotary converters, the three single-phase transformers are connected in mesh. From each of these transformers an extra lead is taken on the low-tension side



to provide a lower voltage for starting the starting motors of the rotaries. In what phase are these extra leads—x, y, and z?—POLYPHASE.

34. Describe the Harrison system of electric signalling for single-line working on tramways.—R. G. R.

ANSWERS.

Question No. 723.—The poles of a shunt-wound direct-current machine (bipolar) are found to be reversed after dealing with a heavy short, the current probably amounting to 350 amperes, the normal full load of the machine being 180 amperes. Can any reason be given for this?

Answer to No. 723 (*awarded 7s. 6d.*).—The explanation of the reversal of poles is a very simple one. It is easily understood that the greater the current delivered by a shunt machine, the smaller will be the voltage—magnetisation assumed constant. For by Ohm's law the loss of pressure in the armature is equal to the current flowing through it × the resistance of the armature. Now the resistance being constant (of course, it increases slightly on larger loads due to heating of the coils), and the magnetisation assumed so, it becomes clear that greater current means greater loss in armature, and therefore less external volts. In Fig. 1 is given the characteristic—the relation between voltage and current—of a shunt machine. The full line indicates the working part of the curve. Of course, there are other things which tend to reduce the pressure also. The existence of the armature cross magnetising turns necessitates the rocking of the brushes in order to obtain sparkless collection of current. This rocking of the brushes produces back magnetising turns, which, reacting on the field magnets, lower the value of the induction, and therefore lower the voltage.

Now, it is the combination of the demagnetising turns on the armature, combined with the lowering of terminal pressure, that produced the effects quoted by "C. W. S." Firstly, on the short happening a tremendous current poured out of the machine. The immediate effect was to lower the terminal voltage of the dynamo. This lowering of the voltage immediately reduced the current in the field magnets, which in turn reduced the excitation of the fields. The existence of the demagnetising turns now made its effect very sharply felt owing to the terrific current passing at the time. Again, down went the excitation and likewise the pressure, until, completely demagnetised by the armature turns, the magnetisation of the fields simply dropped out. By this time no doubt the machine was cut out. When run up again it is extremely probable that there was a small amount of residual magnetism in an opposite direction to the usual "flux," it being left by the *wiping out* action of the back magnetising armature turns. Consequently the machine generates inversely, and likewise the poles are found to be reversed.

The whole action is really due to the effect of the armature in the matter. The dotted line in Fig. 1 is the characteristic of the shunt machine beyond working loads. The machine is designed so that from A to B, the working limits, the pressure drop shall be a certain amount, but beyond this voltage falls off much quicker than formerly, until finally a point, C, is reached where the *magnetisation falls off at a greater rate than the pressure.* The result is that the

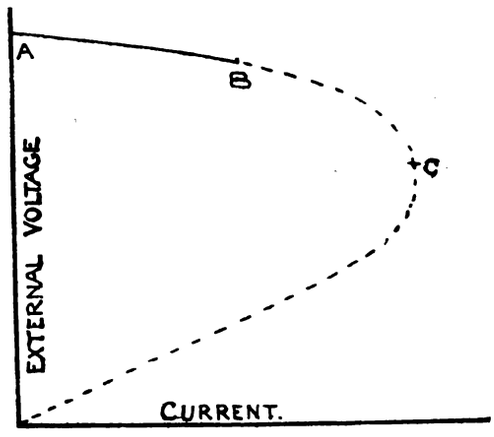


FIG. 1.

magnetisation drops out, and an explanation may be found in the fact that the back magnetising turns are much stronger in effect, the current being greater, and also in the fact that the actual magnetisation (direct) falls off much quicker at small currents (as would flow with decreased terminal pressure) than for normal currents. An examination of Fig. 2, which is an induction curve—that is, practically the relation between lines through armature and current in field coils—will make this clear. X is about the working part of the curve—that is, the position of X indicates the induction and current to be those at normal

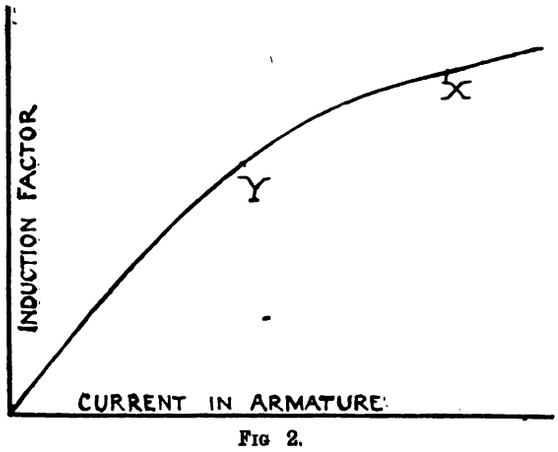

FIG 2.

load. Now, any decrease of current at X would not produce nearly as much effect as a corresponding decrease at Y. Now, any decreases that took place due to fall in terminal voltage, as indicated by the fall in A B (Fig. 1), would only act in the neighbourhood of X: whilst any fall in terminal voltage under short-circuit (the voltage, therefore, as explained before, being small) would be in the region of Y. Therefore, the whole tendency under short-circuit is to demagnetise the fields and remagnetise them in the opposite direction by the back ampere-turns on the armature. This explains the phenomena of reversal.—T. T.

Digitized by Google

Answer to No. 723 (*awarded* 5*s.*).—It is not difficult to give a reason for this reversal of the magnetism when we consider the "characteristic curve" of the ordinary shunt-wound dynamo. In Fig. 1 two characteristic curves are shown for such a dynamo, the one marked A being the internal characteristic, and showing the relation between the total generated E.M.F. and the current in the armature; the other, B, showing the relation between the E.M.F. at the terminals of the machine and the current in the external circuit.

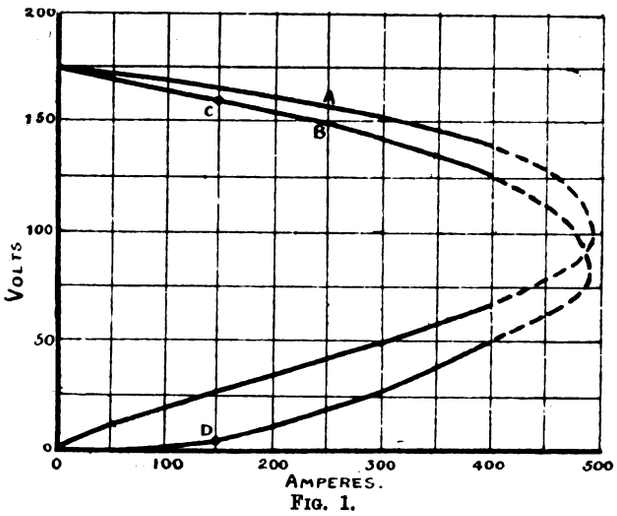

FIG. 1.

Now, suppose the machine is being worked at the point C on the Curve B—that is, it is giving 160 volts at its terminals, and a current of 150 amperes, and the short develops. The current rises and the volts fall along the Curve B, until the bend in the curve is rounded and the unstable portion is reached. The current then falls rapidly, and the voltage also falls, and we again pass through a condition at the point D where the current is 150 amperes. Now, the current in the armature of a dynamo tends to demagnetise the field magnets, because of the forward lead that must be given to the brushes, and this demagnetising action depends only on the current and the angle of lead, and therefore it will have the same value at D as it had at C; but now the volts at the terminals are only about five instead of 160 as before, and therefore the field magnets will be very weakly excited, and it is possible, as seems to have been the case in this example, that the demagnetising action becomes greater towards the end of the curve than the forward magnetising force, and hence the magnetism is reversed in direction in the field magnets.—W. S. P.

Answer to No. 723 (*awarded* 7*s.* 6*d.*).—There are two or three causes which will account for the reversal of shunt-wound dynamos, as described by "C. W. S." To understand the better what actually takes place, it will be necessary to go into a little detail concerning some of the characteristic features pertaining to them. Every such machine has what is termed its "limiting resistance" and its "critical speed." "Limiting resistance" means the lowest amount to which the external resistance can be reduced without causing the external current to fall. If this is exceeded, both volts and current fall back to zero. "Critical speed" refers to the lowest speed at which the voltage generated by a given flux through the armature is sufficient to send a current through the shunt coils large enough to produce that flux. Fig. 1 is an ordinary external characteristic curve of a shunt-wound dynamo, the ordinates representing volts, and the abscissæ current.

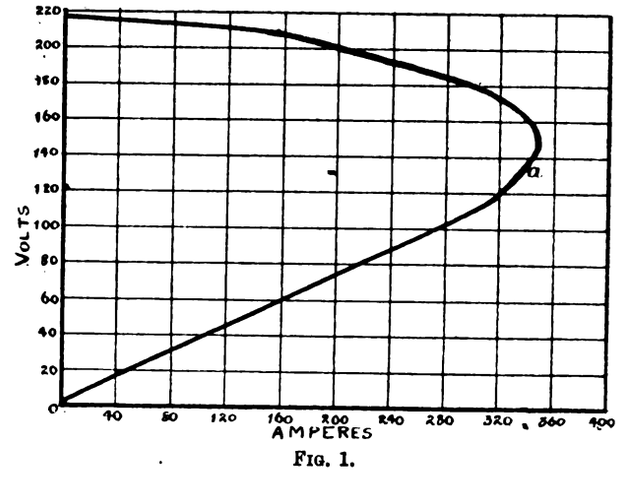

FIG. 1.

First, dealing with the "limiting resistance." When the external circuit is open its resistance is greatest, and the shunt field coils are at their maximum strength. As soon as parts of the external circuit are switched in, the external resistance becomes reduced, and the shunt field coils are proportionally weakened, because both are simply circuits in parallel, and the current flowing through them varies inversely as their resistance. The more the resistance of the outer circuit is reduced, either by the switching in of lamps, etc., or of "short-circuit," the weaker become the shunt coils, and the field-magnet flux is reduced, which results in a drop of voltage. The "limiting resistance" is reached when at a point *a* shown on the curve (Fig. 1) the resistance of the external circuit becomes so low that the voltage across the field coils is not sufficient to maintain the flux which is required to produce the voltage equal to the armature current × its resistance, and the volts and amperes fall back to zero. Secondly, a similar curve might be plotted in the same way, representing amperes and speed. If the speed for any given external resistance be reduced beyond a certain limit, then a point on the curve will be reached when the voltage will drop, and again the dynamo fall back to zero.

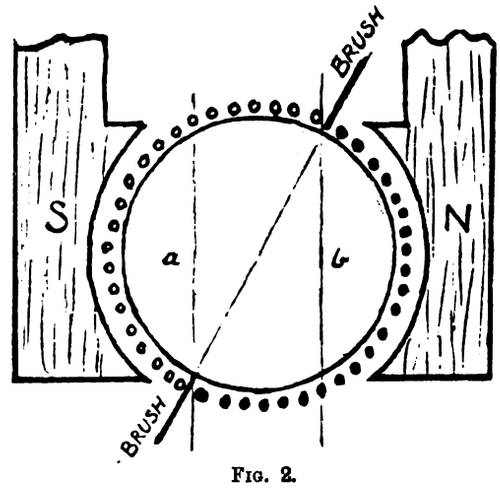

FIG. 2.

Now, let us see what happens when the "short-circuit" takes place. First, the external resistance is so much reduced that an abnormal current of 350 amperes is momentarily produced, which means that the point of "limiting resistance" has been over-reached, also the "critical speed" due to the extra load, and the machine falls back to zero. But not only is this feature (shown

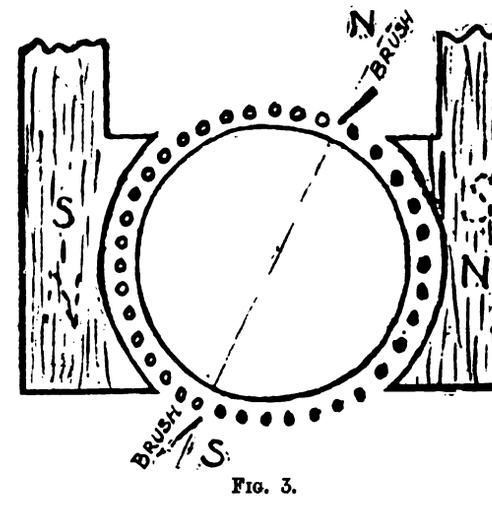

FIG. 3.

Digitized by Google

by the characteristic curve) answerable for demagnetisation, but also for the reversal of polarity which sometimes takes place. Fig. 2 is an ordinary method of illustrating how the "back ampere-turns" of the armature react on the field. The neutral axis, or line of commutation, is advanced from the normal to make up for cross magnetisation and distortion of the field due to heavy load. This in a bipolar machine, unless the field-magnet strength is considerable in proportion to the armature, is appreciable. The result is that between the brushes there are a number of ampere-turns (shown between the two vertical and parallel lines, *a* and *b*) which are setting up a magnetic field in direct opposition to the flux of the field magnets. When the "short-circuit" takes place, an excessive current raises the value of these ampere-turns much above the weakened ampere-turns of the field, not only aiding the curve to drop as shown in Fig. 1, but completely overpowering them, and magnetising the fields in an opposite direction. This may also be further accentuated by "cross magnetisation." The current flowing through the armature, being produced by the shunt field, might lag somewhat when the shunt fails, owing to self-induction, not only producing final results similar to the foregoing, but also because of its magnetic axis being as shown in Fig. 3, different polarities are set up, as shown by the dotted letters. When the "short-circuit" has been removed, and the machine again started, it builds up with opposite polarities owing to this opposing magnetism being left as residual. These few suggestions will probably help "C. W. S." to form some idea as to what took place.—WILLIAM BEARD.

Question No. 724.—A three-phase high-pressure alternator has too large a pressure-drop from no load to full load. What means are there of remedy ing this?

Answer to No. 724 (*awarded* 7*s.* 6*d.*).—The regulation of the supply voltage of any alternating-current generator is dependent upon two things: (1) the mechanical governing of the prime mover; (2) the electrical design and nature of load.

1. Should it be found that there is a considerable drop in speed between no load and full load the fault is mainly due to the engine, and attention should be paid to the working of the governor and maintenance of full steam pressure at engine steam valve. Also the exciter, if separately driven, should not run slower due to decrease in steam pressure or any other cause. If the exciter is driven from the same engine by belt or direct coupled to the alternator, the governing of the engine is of the utmost importance, as when the load goes up, the speed decreases, causing a decrease in exciter voltage, so that we have a double reduction in our supply voltage. In any case some hand regulation is necessary to compensate for decrease in engine speed, and the drop in volts due to the increase of current in generator armature.

2. If the speed regulation is good, then we must look to the generator for the reason of the excessive pressure drop. Here, again, we have two things to consider: (*a*) the design of the machine, (*b*) the nature of the load.

(*a*) If the machine is over-rated or run at a higher speed than normal, we are bound to get a poor regulation. The pressure drop from no load to full load of an alternating-current generator is due to a combination of two things—viz., the armature resistance and its reactance. The resistance is a perfectly definite quantity, and cannot be altered without rewinding the machine, whilst the reactance is given by $(6{\cdot}28\ n\,L)$, where n is the frequency in cycles per second, and L is the inductance of the armature. The impedance, or term which governs our regulation, is equal to $\sqrt{(6{\cdot}28\ n\,L)^2 + R_a^2}$, and to improve our regulation it is necessary to reduce this quantity. There are, however, only two terms which permit of reduction—viz., the frequency or the inductance. The frequency varies directly with the speed, and to keep the volts constant the normal field current will have to be increased, and at the same time we stiffen the field by working the whole magnetic circuit at a higher flux density. The permissible reduction in speed will depend on several factors; the engine will have a smaller capacity for overloads if it is direct-coupled; any motors on the circuit will run at a correspondingly reduced speed, and the no-load currents will be higher. Also the no-load losses of any transformers will be increased, and if this generator is running in parallel with any others their speed will have to be reduced for synchronous running. The self-induction, L, of the armature may be reduced by increasing the reluctance of the magnetic circuit. This is done to a small extent by decreasing the speed and keeping the voltage constant, but we may make a further and material difference without interfering in any way with any apparatus on the circuit. This further reduction may be made by increasing the air-gap, and the extent to which this can be carried out depends on mechanical difficulties and the extent to which the field current may be increased without dangerous heating in the field coils themselves. The field may either be turned (if revolving field) or slots may be cut across the face of the pole, care being taken in either case to chamfer off all corners to prevent fringing and noise. The slots need not be cut deep, and should be not more than 2in. apart, the size and number of slots depending on the type and size of pole. At the same time it may be possible to reduce leakage and also variation in flux distribution by means of "damping coils" or wedges of copper. These may be placed in the slots already mentioned and an efficient electrical circuit completed outside, round the pole. The limits to which this increase of air-gap may be carried will depend upon the mechanical method by which the field coils are secured (if the machine is of the revolving-field type, otherwise this is not so important), the safe increase of field current and corresponding increase of field voltage, and also we must bear in mind the fact that we may be increasing the leakage flux by a considerable amount; some increase cannot be avoided, and it will vary the shape and size of poles and pole-tips.

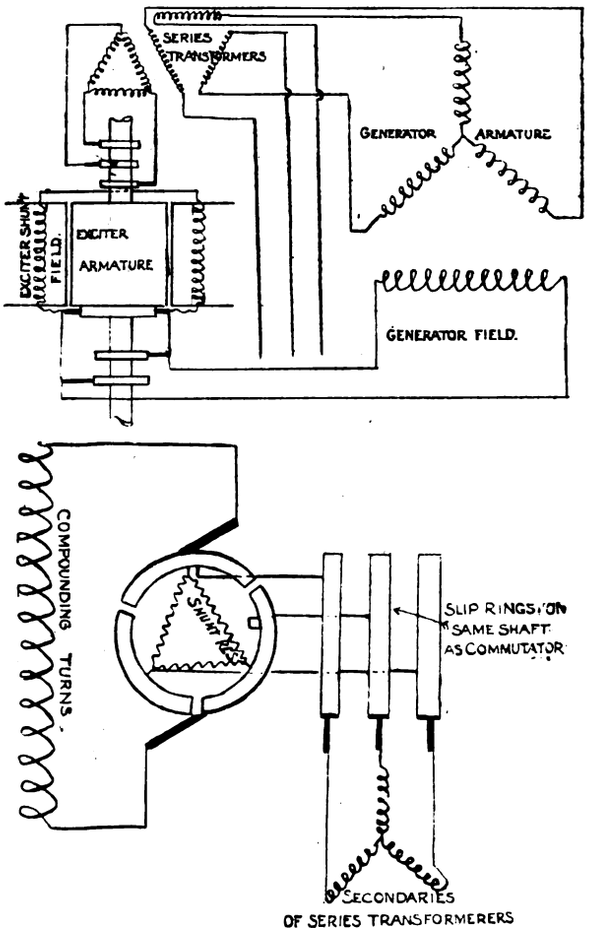
(*b*) The second factor, which has a most important bearing on the regulation of an alternating-current generator, is the power factor. A good alternating-current machine may have a 4 to 6 per cent. drop from no load to full load with constant excitation and a power factor unity, but when this power factor falls to ·8 or ·7, as is the case in many power supply schemes, we may only have a 20 per cent. regulation. From this it will be seen that it is desirable to keep our power factor as high as possible. A low power factor may be due to a considerable portion of the load being due to small induction or synchronous motors or a large number of small transformers. In the case of synchronous motors, a considerable improvement may be effected by adjusting the field current to bring the current supply as low as possible, or if power factor indicators are installed, the field current may easily be so regulated as to give a slightly leading current. The same remark, of course, will refer to rotary converters. Small or partially loaded induction motors always decrease the power factor, especially if they are often started and stopped. Slip-ring induction motors are better than the squirrel-cage type in this latter respect, and large motors have a good power factor if they are loaded up to at least 75 per cent. of their normal capacity. A poor power factor may be due to there being a large number of small transformers on the circuit; if a number of these can be replaced by one larger one, not only will the power factor be improved, but the efficiency also will materially benefit by the change.

Should neither of these two methods be practicable or the improvements possible only small, then the only way out of the difficulty will be to add some compounding device. Two types which might possibly be tried with advantage work as follows: The Rice-Reist compensated exciter depends for its action on the fact that a lagging current tends to increase the field of a synchronous motor or rotary converter. The exciter has three slip-rings arranged on its shaft and suitably connected up to its armature winding as a rotary converter; current is led in through these three rings from series transformers, the primaries of which are in the main generator armature circuit. Even if the power factor be unity, we get a certain amount of boosting up of the exciter voltage, by reason of the series transformers supplying current, when the current through the primaries is sufficiently large, and the exciter acts as a rotary converter, whilst if the power factor is less than unity and lagging, the effect will be to still further increase the exciter voltage by increasing its field strength. The condition for this arrangement is that the product of

Digitized by Google

the poles and speed in revolutions per minute should be the same for both alternator and exciter, so that if the exciter is on the same shaft as the alternator, then the number of poles must be the same on both. Should the exciter be separately driven, then some positive method such as chain or gear must be employed, and the positive drive so arranged that the E M.F.'s on the exciter and alternator are in phase.

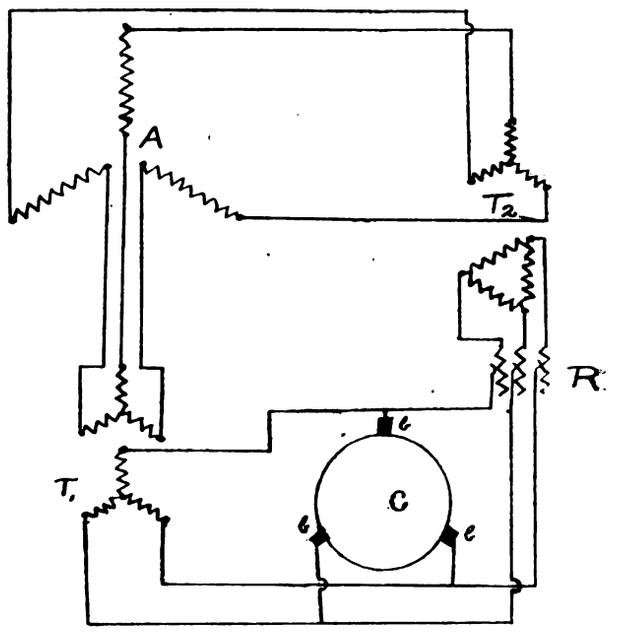
In the Rice-Reist machine the exciter field is so arranged that it can be rocked concentrically with its armature, and so regulate the amount of compounding. The diagram of connections will show the general arrangement. Another but not so satisfactory method is to fix a rectifying commutator on the alternator shaft and to rectify the secondary current from the series transformers, and pass the rectified current through additional coils placed on either the exciter field or the alternator field itself. With three-phase current it is possible to get practically direct current, not



merely unidirectional current, and sparking on the commutator can be avoided by inserting a resistance between each commutator segment. The arrangement is shown diagrammatically herewith, and the number of commutator segments required will be 1½ the number of poles on the alternator.—R. H.

Answer to No. 724 (*awarded* 5*s.*).—The excessive drop in pressure in the alternator in question between no load and full load may be due to faulty design, and therefore, in order to remedy the fault, would necessitate some constructional alteration. The principal causes of pressure-drop in alternators are armature reaction, increase of field-magnet and armature leakages between no-load and full load. Moreover, eddy-current losses and ohmic loss in armature winding affect it more or less. The armature flux due to the armature ampere-turns may be considered as having two components, one having the same path as the field flux and generally opposing it, owing to armature current lagging behind the pressure. The other component—the armature leakage flux—traverses a path not common to the field flux, and gives rise to the self-induced E.M.F. of the armature which is in quadrature with the armature current. The armature leakage flux, being confined to the neighbourhood of the armature winding, depends upon length of air-gap, form and dimensions of armature teeth, and the degree of saturation of teeth, air-gap, and pole-shoes. This flux, therefore, depends largely upon the construction of the machine. The armature reaction depends upon the relation, as regards phase, between the current and pressure in the armature. If the current lags behind the pressure, the effect of the armature reaction will be to oppose the field flux, and, if it be leading, to strengthen it. The armature reaction, therefore, can be increased or diminished by varying the power factor of the load. Its effect in causing pressure drop is less the higher the saturation of the field magnets. A well-saturated magnetic circuit conduces to good pressure regulation, as armature reaction will have less effect on the field. On the other hand, if the magnetic circuit be too highly saturated, the field leakage between no load and full load may be very great.

Synchronous alternators of the revolving field type excited and compounded on the Heyland principle have no pressure drop, and hand regulation of the field circuit in order to keep the pressure constant is not required. In the figure, C is a cross-connected commutator, with brushes, *b*, *b*, *b*, for the commutation of the alternating currents supplied to it from the transformers, T_1 T_2. The resulting unidirectional current is led around the field magnets by means of a number of inter-connected parallel circuits, which are connected to C instead of to the usual slip-rings.



T_1 is a current transformer in series with the armature windings, and supplies the "compounding" current. T_2 is a pressure transformer for supplying the exciting current. R is an adjustable resistance in the exciting current circuit.

A modification of the above method consists in compounding, where it exists, the direct-coupled exciter. The brushes in this case are connected to an auxiliary winding on the field magnets of the exciter, the original shunt winding of the exciter being retained. The compounding current, which may be obtained from a current transformer in series with armature winding (such as T_1 in the figure), is delivered to slip-rings, each of which are connected at suitable points to the commutator. The ordinary shunt winding of the exciter furnishes the exciting current necessary for the alternator at no load, and the current in the auxiliary winding furnishes the extra excitation necessary to keep the pressure constant (or, if necessary, to increase the pressure) at the terminals of the generator as the load increases.—H. J. W.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

QUESTIONS.

735. What is the most practical (not text-book) method of quickly locating faults in underground three-core lead-covered distributors (laid solid) or concentric feeders (in conduits) on a three-wire continuous-current system? Consider the following faults: (1) two cores short-circuited; (2) two cores short-circuited with "earth"; (3) earth on one core (unusual). It is required—first to quickly locate between disconnecting boxes, and then locate closely. The writer (for the latter) favours a simple system with comparatively large testing currents, such as taking drop of potential from each end of faulty main to earth, with heavy constant current passing along whole main, but fails to see how this method can be applied in the cases of (1) and (2). Accurate bridge tests, in the writer's opinion, are almost impossible for street work. Give particulars of most suitable instruments and apparatus that can be quickly arranged for tests.—R. V. M.

ANSWERS.

Question No. 724.—A three-phase high-pressure alternator has too large a pressure-drop from no load to full load. What means are there of remedy ing this?

Answer to No. 724 (*awarded 7s. 6d.*).—The fall of voltage in an alternate-current generator is due to two primary causes—viz., the self-induction of the armature and the demagnetising action of the current it carries. To reduce the former in the case of the armature with well open slots, the width of the air-gap should be increased (see Fig. 4), and in the case with closed slots the bridge at the top of the slots should be cut away. With regard to the first case, it is shown below that any advantage that is gained by increasing the gap is counterbalanced by other effects; and with regard to case 2, the remedy is, of course, impracticable if the machine is already built, and can only be adopted in constructing new machines of the same type.

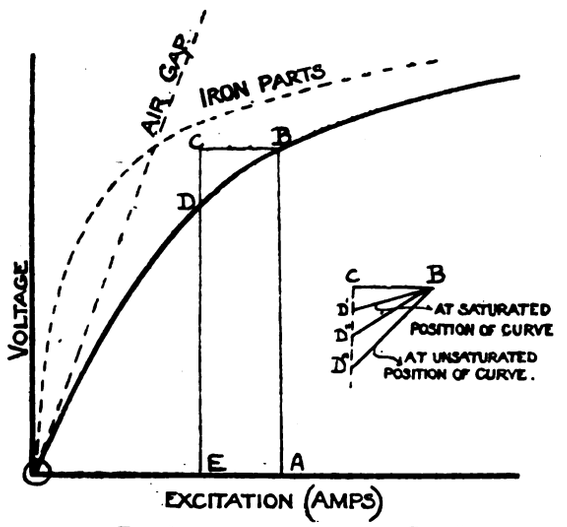

FIG. 1. FIG. 2.

It therefore remains to examine the demagnetising action of the armature currents, which will be done by reference to the no-load saturation curve shown in Fig. 2. Suppose that A B is the no-load voltage produced by the amount of excitation, O A. Then if B C is the equivalent value of the armature demagnetising effect on the magnet's current, only flux corresponding to the excitation, O E, flows through the magnet system, and the voltage, E D, only is generated. C D is, therefore, the voltage drop due to this cause. Now, if the points B and D are not too far apart, that portion of the curve between them may be taken as straight, and we can then consider B C D as a triangle in which the side C B is of a fixed length, the angle B C D is a right angle, and the angle C B D is a varying one depending upon the position of B on the saturation curve. In Fig. 2 a number of triangles have been drawn on top of one another fulfilling these conditions for different positions of B on the curve, and it is noticed that for the same amount of demagnetisation more or less voltage loss results, according to whether B is on the steep or the flat part of the curve. We therefore want to reduce the steepness of the curve at the point of no-load volts. Now, the saturation curve is made up of two curves—namely, the excitation for the air-gap and the excitation for the iron parts (see Fig. 1). We may, of course, make the slope of the curve less by increasing the excitation necessary for both parts, by making the gap longer and the iron parts more saturated, but if the magnets cannot be given more exciting current, either

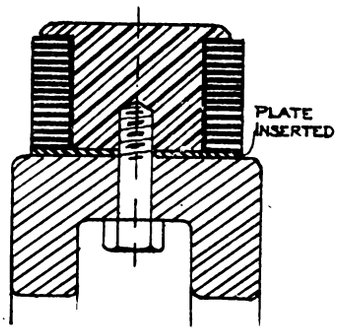

FIG. 3.

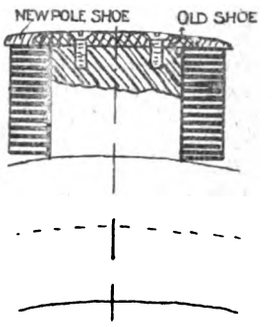

FIG. 5.

owing to the necessary higher voltage not being available, or the increased current heating the coils too much, this is not a possible solution. Therefore, to give the same excitation to attain the same voltage, but also to have the curve at this point less steep, the excitation for the gap must be diminished, and that for the iron increased by the same amount, because the slope of the air curve is constant, while that of the iron curve is continually diminishing. There are two methods of diminishing the excitation for the gap, and these are to make the width of the gap less by packing the pole-piece up with a plate of suitable thickness, as indicated in Fig. 3, or by fitting on a wider pole-shoe than the machine already has and leaving the width of gap the same (Fig. 5). There is an objection to the former procedure and an advantage in the latter. If open slots are used on the armature, most of the armature leakage goes

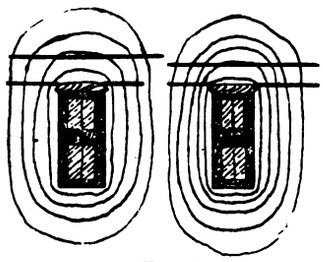

FIG. 4.

into the pole (Fig. 4), and the chief reluctance offered to these lines is therefore the gap, and if the gap is diminished the self-induction of the armature will therefore be increased. With regard to the second procedure, the self-induction is not appreciably increased, but as there will be more armature conductors under the pole at one time, the armature magnetomotive forces will set up more cross-magnetisation and less *de*-magnetisation. The iron parts may be made more saturated by turning some metal off the pole-cores. It will be noticed that if the iron parts are already saturated, and the curve has therefore already become flat, the remedy is not so effective as when they are only partially saturated. C. T. R.

Answer to No. 724 (*awarded* 5*s.*).—If there is any margin in the excitation—*i.e.*, if when giving its full-load output there is some resistance in series with the field winding and the winding does not overheat—the drop can be improved in various ways; but if the machine can only just do its full load at present, the reduction of the drop would be a

Digitized by Google

difficult matter, necessitating partial or complete rewinding of the machine and involving its return to the makers. Assuming that there is a margin, the object to be aimed at in order to reduce the drop is the increase of the ratio of field ampere-turns to armature ampere-turns, for the drop varies almost in inverse proportion to this ratio. For a given increase in this ratio, a minimum increase in excitation would be required if the change is produced by reducing the turns in the armature coils, for this not only reduces the armature ampere-turns, but increases the field ampere-turns required to produce a given terminal voltage by about the same percentage, thus increasing the ratio and reducing the drop approximately as the square of the change in excitation. This method is, however, a troublesome one, as it involves the partial rewinding of the armature coils, and could only be satisfactorily carried out by the makers. A simpler method, though one involving about twice as great an increase in excitation as in the last method for a given improvement in drop, consists in increasing the air-gap resistance of the machine either by turning down the armature or the magnets or by reducing the pole-face area. Instead of increasing the air-gap resistance, the same increase in excitation can be obtained by increasing the iron saturation either through cutting down the cross-section of a part of each magnetic circuit or through artificially increasing the magnetic leakage—*e.g.*, by putting iron plates between neighbouring pole-pieces, as in Fig. 1. This last method is, however, less satisfactory than the others, as the iron plates not only increase the field leakage but tend to increase the armature leakage as well, and the latter, of course, adds to the drop instead of reducing it.

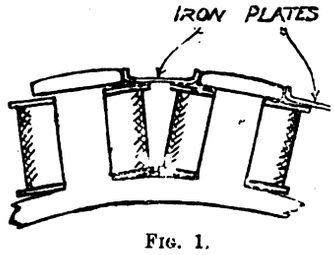

FIG. 1.

A quite different method of reducing the drop of an alternator consists in compounding it by one of the numerous processes which have been devised for the purpose. Thus, a part of the output current of the machine can be rectified (by fixing a small rectifying commutator on the alternator spindle) into a pulsating direct current, and this can be passed round an additional compounding winding on the field poles—the total excitation increasing with the load much as in a direct-current compound dynamo. As an alternative the existing exciter can be replaced by one of the patented compounding exciters—such as Hutin and Le Blanc's or the one made by the General Electric Company of America. Such an exciter could be arranged to keep the terminal voltage constant at all loads or even to increase the voltage as the load increases, irrespectively of whether it is an inductive or a non-inductive load. Any of these compounding arrangements, however, involve expensive alterations when applied to an existing alternator.—Q.

Question No. 725.—A double-cylinder, double-acting, high-speed steam-engine of 320 i.h.p. is found from consumption test to require 42·5lb. of steam per indicated horse-power hour. It exhausts against a pressure of 12lb. per square inch above atmosphere. Initial pressure of steam in the engine cylinders is 80lb. per square inch. The mechanical equivalent in foot-pounds of the heat liberated by the fall in pressure from 80lb. to 12lb. is not equal to more than half the 33,000 foot-pounds of work actually performed. As the heat units required must be from theoretical considerations more than the equivalent of 1 h.p., explain why the work performed is apparently in excess of the heat utilised.

Answer to No. 725 (*awarded* 7*s.* 6*d.*).—It appears to me that the reason for "E. G. B.'s" query is that he has not used the correct method in calculating the work done by the steam during expansion. I have worked out two cases of the problem, the first in which the steam is assumed initially dry and to expand down to exhaust pressure, and the second in which the steam contains initially 10 per cent. of moisture (dryness fraction = ·9) and only expands to 7lb. per square inch above the exhaust pressure (both these conditions entail a loss of heat), and found in both cases that the work equivalent to the expansion considerably in excess of the 30,000 foot-pounds made use of. Adiabatic expansion is assumed in both cases.

Case 1.—The temperatures corresponding to pressures of 95lb. per square inch absolute and 27lb. per square inch absolute are 323·94deg. F. and 244·33deg. F. respectively (Pullen). Now on a temperature entropy chart draw horizontal lines, A B at 95lb. per square inch absolute and C E at 27lb. per square inch absolute (or at corresponding temperatures). Then at B we have the steam as initially in the cylinder, the line B B represents adiabatic expansion, and the work done during expansion is given (in heat units) by the area C A B D. As the portion A C of the curve is practically a straight line, this area equals $B D \times \frac{A B + C D}{2}$.

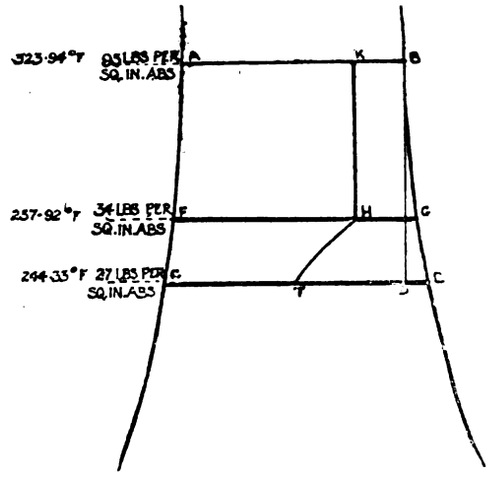
But B D equals the drop of temperature = 323·94 − 244·33 = 79·61deg. F.

A B equals the entropy of 1lb. of steam at 95lb. per square inch absolute = 1·15 ranks.

C D equals the entropy of 1lb. of steam at 27lb. per square inch absolute = 1·25 ranks.

Hence work done = 79·61 × 1·2 Fahr. heat units.

To convert this to foot-pounds we must make use of Joule's equivalent, which is one Fahr. heat unit equals 778 foot-pounds (Rowland). Hence foot-pounds of work



liberated by 1lb. of steam during expansion equals 79·61 × 1·2 × 778 = 74,322 foot-pounds.

But we are told that the engine uses 42·5 per indicated horse-power hour, and, therefore, $\frac{42·5}{60}$ = ·708lb. per indicated horse-power minute. Therefore the foot-pounds of work liberated per minute = ·708 × 74,322 = 52,620 foot-pounds, while the actuated work used is 33,000 foot-pounds.

Case 2.—In this case draw another line, F G, at 34lb. per square inch absolute (or corresponding temperature 257·92deg. F.), and divide A B at K so that A K ÷ A B = 9. Then, as before, the line K H represents adiabatic expansion to H. After the point H we have the steam at constant volume, but lowering in temperature; we must therefore proceed along a constant volume line till we cut C D in T. Then the work done during the fall of temperature is given by the area C A K H T, and this is most easily found by finding separately the two areas, F A K H and C F H T, and adding them together (H T is practically a straight line). This should be converted to foot-pounds and multiplied by ·708 as before. In this case I find the work liberated equals 46,160 foot-pounds. How "E. G. B." manages to get 16,000ft. I cannot imagine—H. E. H.

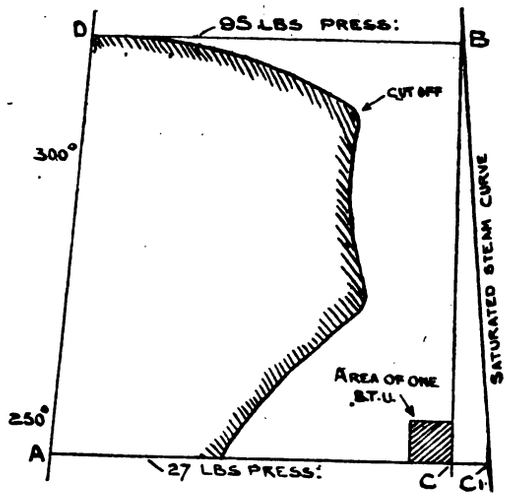
Answer to No. 725 (*awarded* 7*s.* 6*d*).—It would appear from the statement of this question that an attempt has been made to compare the test performance of a steam-engine with that which under the thermal limits imposed it might be expected to give from theoretical considerations alone. Further, it seems that the by no means uncommen error has been made of concluding that the heat available for the performance of work in a steam-engine cylinder is solely that represented by the difference in the total heat of the steam at the upper and lower limits of pressure given.

Digitized by Google

That this must have been so is evident from the following figures.

Total heat of steam at 95lb. pressure absolute = 1,180·3; at 27lb. = 1,155·8. Heat liberated by fall in pressure = 24·5; and $\frac{24·5 \times 778 \times 42·5}{60}$ = 13,500 foot-pounds, or about $\frac{13,500}{33,000}$ = 0·41, or less than the ½ h.p. mentioned.

When steam in expanding does work, it is done by virtue of its intrinsic energy, or largely at the expense of its latent heat and partly by loss of sensible heat or fall in temperature accompanying fall in pressure during expansion. It follows, therefore, that the condition of the steam or the quantity present in the engine cylinder as steam after the performance of useful or external work must be less than that admitted up to the point of cut-off, due to this heat conversion to mechanical work, and that as expansion proceeds, and the further it is continued, so the steam becomes wetter. This is true theoretically, but practically so many causes (among them the influence of initial condensation and subsequent re-evaporation due to abstraction of heat by cooler and restoration of heat from hotter surfaces) contribute to modify this conception, that usually the steam is actually drier after expansion than at the point of cut-off in the cylinder. This brief statement of facts is essential in order that it may be realised that the heat units required as the equivalent of the work done, or horse-power, are obtained from the internal or latent heat of the steam.



Returning to the case under consideration, the effect of expanding steam from 80lb. pressure to 12lb. may be graphically shown by merely drawing the adiabatic expansion line upon the temperature entropy diagram, and so ascertaining the condition as to dryness of the steam upon the assumption that it was dry or saturated steam at cut-off. The accompanying figure gives that part of the temperature entropy diagram which includes the required pressure range. Expansion commences at B, and follows the adiabatic line to C, at which point the steam occupies 14·2 cubic feet per pound. If the steam was all steam at this stage, or dry, it would occupy a volume of 15·2 cubic feet per pound, and the point C would be at C_1, or on the saturated steam curve. The proportion of steam present may be found from the ratio $\frac{A\ C}{A\ C_1}$, which in this case is $\frac{1}{1·08}$, or 92·5 per cent. The heat available per pound of steam expanding under these conditions, and represented by the area D B C A, is, by approximately correct direct measurement, 91 thermal units. (The equivalent value in thermal units of 1 h.p. is $\frac{33,000}{778}$ = 42·5.) By the test result figures, $\frac{42·5 \times 91}{60}$ = 64·5 thermal units were required per horse-power. The standard thermal efficiency of the engine is therefore

$$\frac{42·5 \times 100}{64·5} = 65·8 \text{ per cent.}$$

The point of cut-off in the engine cylinders is not stated in the question, and if an indicator diagram had been produced, more complete information might have been given. An engine of this type would, however, cut off at about half stroke, and if the admission and expansion lines from the indicator diagram were plotted on the temperature entropy diagram, an area of form indicated would be obtained. A comparison between D B C A and this area then enables the thermal efficiency to be graphically represented and an examination of the sources of heat loss to be made if desired.—Q. E. D.

Answer to No. 725 (*awarded* 7*s.* 6*d.*)—"E. G. B.," in calculating that the work performed by the steam, has apparently *neglected* the work done by the steam before the cut-off occurs, and so obtains the startling result that the engine indicates nearly twice the power supplied by the steam. The following shows that in reality the indicated power of the engine in question is only a little over half the mechanical equivalent of the heat liberated by the steam had it expanded completely and under ideal conditions. At 80lb. per square inch—*i.e.*, 95lb. per square inch absolute—the volume of 1lb. of saturated steam is 4·56 cubic feet, while at 12lb. per square inch—*i.e.*, 27lb. per square inch absolute—the volume is 14·9 cubic feet. Assuming ideal conditions, the work done between admission and cut-off is equal to the product of the effective steam pressure and the distance through which it acts

$$(95 - 27)\ 144 \times 4·56 = 44,700 \text{ foot-pounds}$$

done by 1lb. of steam before expansion commences. For these ideal conditions the law of expansion may be taken as

$$P\ V\ n = \text{constant},$$

where $n = 1·13$, the work done being the area of this curve, and is given by

$$\frac{P_1\ V_1 - P_2\ V_2}{n - 1}.$$

Substituting the actual values of pressure and the volume occupied by 1lb. of steam,

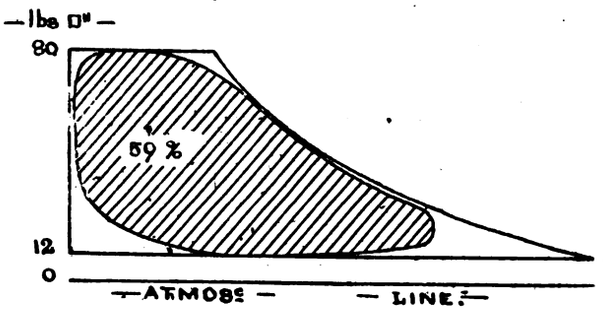
$$\frac{(95 \times 144 \times 4·56) - (27 \times 144 \times 14\ 9}{1\ 13 - 1\ 0}$$

= 34,600 foot-pounds of work done during complete expansion. The total work is, therefore, 44,700 + 34,600, or 79,300 foot-pounds per pound of steam. The actual engine uses 42·5lb. per hour, or 0 708lb. per minute, to indicate 33,000 foot-pounds, this weight of steam theoretically giving

$$0·708 \times 79,300 = 56,100 \text{ foot-pounds},$$

the efficiency of the cycle performed by the engine in question being equal to

$$\frac{33,000}{56,100} = 58·8 \text{ per cent.}$$



The accompanying diagram shows the ideal diagram, inside which the shaded area represents the probable actual indicator diagram obtained, this being 59 per cent. of the larger, and also shows the losses due to clearance, incomplete expansion, compression, etc.—J. K. C——S.

Answer to No. 725 (*awarded* 5*s.*).—The number of units of heat in 1lb. of steam at 95lb. absolute pressure above that in water at 32deg. F. is equal to 1,180 B.Th.U.; the number in 1lb. of steam at 27lb. absolute pressure above that in water at 32deg. F. is equal to 1,156 5 B.Th.U. The heat units liberated by the 42 5lb. of steam—the weight used per horse-power hour—in expanding from 95lb. to 27lb. pressure absolute are, apparently, 42·5 (1,180·7 − 1,156·5) = 1,028·5 B.Th.U. Taking Joule's equivalent at 772, these heat units converted into units of work are

Digitized by Google

equal to $1,028{\cdot}5 \times 772 = 794,002$ foot-pounds. Now, the work actually performed by the steam in expanding between the above pressures is equal to one hour horse-power, or 1,980,000 foot-pounds—over twice the amount calculated above. It is a fundamental principle of all heat engines that the quantity of work done depends on the amount of heat which is converted into work; steam, or gas of any kind, is merely the agent by which the conversion takes place, and can do no work without yielding up heat. Now, it is a well-known fact that if saturated steam be expanded in a cylinder, and does work, that in addition to the fall in temperature of the steam due to the reduction of pressure, a certain quantity is condensed, giving up its latent heat. The quantity of steam condensed is such that the latent heat liberated is sufficient to meet the increase in the latent heat at the reduced pressure plus those units which with the units of heat liberated by the fall in temperature of the steam are, when converted into work, equal to the work actually performed by the steam upon the piston (I have neglected those units required to meet the losses due to radiation, etc.). If the cylinder be steam jacketed and the rates of expansion are high, the heat units liberated by the steam condensed in the jacket are, practically, a measure of the work done in the cylinder. In this particular case the work actually performed in one hour by the 42·5lb of steam in expanding from a pressure of 95lb. absolute to 27lb absolute is equal to 1,980,000 foot-pounds, which converted into heat units equal, say, 2,565 B.Th.U. The temperature corresponding to 95lb. absolute is 323·9deg. F., and that corresponding to 27lb. absolute is 244·3deg. F., therefore the sensible heat units liberated by the 42·5lb. of steam in expanding between these pressures are equal to $42{\cdot}5\ (323{\cdot}9 - 244{\cdot}3) = 3,383$ B.Th.U. If no condensation took place during expansion, the increase in the latent heat (assuming the specific heat to remain constant) would account for $42{\cdot}5\ (943{\cdot}1 - 886{\cdot}3) = 2,414$ B.Th.U., leaving 969 B.Th.U. to be converted into work This quantity is 1,596 B.Th.U. short of that required to produce the actual work done in the cylinder. This deficiency would be met by a certain portion of the steam being condensed, and thus parting with its latent heat. The latent heat of steam at 27lb. absolute pressure is equal to 943·1 B.Th.U., therefore the weight of steam condensed is equal to $\frac{1,596}{943{\cdot}1}$, nearly 1·7lb., or, 4 per cent. of the steam used per horse-power hour. As already stated, this quantity does not provide for the losses due to initial condensation, radiation, etc —E. G. S.

Answer to No. 725 (*awarded* 5*s*).—The direct answer to this question is that condensation takes place during the expansion of the steam, and thus the steam gives up some of its latent heat, which is converted into mechanical work. The weight of exhaust steam discharged in the form of vapour is less than the corresponding weight introduced into the cylinder, even when not taking into consideration the further condensation caused by the alternate heating and cooling of the cylinder walls. In what follows a knowledge of the elementary principles of thermodynamics and of Carnot's cycle for steam is assumed. A perfect heat engine, working on Carnot's cycle, receiving a quantity of heat Q at an absolute temperature T_1, and rejecting heat at an absolute temperature T_2, will convert the quantity of heat

$$Q\,\frac{T_1 - T_2}{T_1}$$

into mechanical work. Now imagine an engine which takes in different quantities of heat, Q_1, Q_2, etc, at absolute temperatures T_1, T_2, etc., and rejects heat at an absolute temperature T_0. As the engine is a perfect one, all the heat taken in will be used as efficiently as possible, so that the total work done will be

$$Q_1\,\frac{T_1 - T_0}{T_1} + Q_2\,\frac{T_2 - T_0}{T_2} + \text{etc.}$$

Now consider a perfect steam-engine, working on the following cycle: (1) gradual heating of the feed water from the condenser temperature, T_2 (absolute), to the boiler temperature, T_1; (2) evaporation of the quantity of steam, say 1lb., used per stroke at temperature T_1; (3) adiabatic expansion down to T_2 and condenser pressure; (4) condensation at T_2. No actual steam-engine working between the same limits of temperature can convert a larger portion of the heat received into work, hence this engine may be used as a standard of comparison for actual steam-engines. For purposes of calculation we may consider the feed water to take up its heat in a series of infinitesimal instalments at a series of temperatures from T_2 to T_1, from a series of imaginary sources, each of which has the same as the water when it is brought into contact with it. Let $d\,Q$ be any small quantity of heat taken up by the feed water at a temperature T lying between T_2 and T_1. This heat will produce the amount of work

$$\frac{d\,Q\,(T - T_2)}{T}$$

expressed in British thermal units. If h_2 is the total heat of the feed water leaving the condenser and h_2 its total heat at boiler temperature, the total work due to the heat taken in by the feed water before it is converted into steam will be

$$\int_{h_1}^{h_1} \frac{dh\,(T - T_2)}{T} \quad \ldots\ldots \quad (1)$$

The remainder of the heat taken in is the latent heat of the steam, or a fraction, q_1, of it, if q_1 is the dryness fraction of the steam as it leaves the boiler. This heat is all taken in at temperature T_1, and the work due to it is

$$\frac{q_1\,L_1\,(T_1 - T_2)}{T_1} \quad \ldots\ldots \quad (2)$$

L_1 being the latent heat of 1lb. of steam at T_1. Hence the total work done by the engine is

$$W = \int_{h_2}^{h_1} \frac{dh\,(T - T_2)}{T} + \frac{q_1\,L_1\,(T_1 - T_2)}{T_1}$$

$$= \int_{h_2}^{h_1} dh + T_2 \int_{h_2}^{h_1} \frac{dh}{T} + \frac{q_1\,L_1}{T_1}\,(T_1 - T_2)$$

$$= h_1 - h_2 + T_2 \log_e \frac{T_1}{T_2} + \frac{q_1\,L_1}{T_1}\,(T_1 - T_2)$$

since the specific heat of water may be taken as unity.

$$\therefore W = (T_1 - T_2)\left(1 + \frac{q_1\,L_1}{T_1}\right) - T_2 \log_e \frac{T_1}{T_2}. \quad (3)$$

The whole heat taken in is

$$T_1 - T_2 + q_1\,L_1,$$

and the heat rejected is $q_2\,L_2$, since the only rejection of heat is during the condensation at T_2, q_2 and L_2 being the dryness and latent heat respectively at temperature T_2. Hence, since heat taken in = work done + heat rejected,

$$T_1 - T_2 + q_1\,L_1 = (T_1 - T_2)\left(1 + \frac{q_1\,L_1}{T_1}\right) - T_2 \log_e \frac{T_1}{T_2} + q_2\,L_2$$

$$\therefore \frac{q_2\,L_2}{T_2} - \frac{q_1\,L_1}{T_1} = \log_e \frac{T_1}{T_2}. \quad \ldots \quad (4)$$

This equation gives us the dryness, q_2, at the end of expansion. In the actual case under consideration, $T_1 = 785$, $T_2 = 705{\cdot}5$, $L_1 = 885{\cdot}3$, and $L_2 = 942$. Assuming steam to be initially dry, $q_1 = 1$. Hence

$$q_2 = \frac{705{\cdot}5}{942}\left(\frac{885{\cdot}3}{785} + 2{\cdot}3 \log_{10} \frac{785}{705{\cdot}5}\right) = 92{\cdot}3 \text{ per cent.}$$

As the engine is non-condensing, the heat taken in is really

$$q_1\,L_1 + T_1 = 1,670 \text{ B.Th.U.},$$

and the heat rejected is

$$q_2\,L_2 + T_2 = 1,573.$$

Hence the greatest amount of heat that can be converted into work is $1,670 - 1,573 = 97$ B.Th.U. per pound of steam. As 42·5lb. are actually used per indicated horse-power hour, the actual work obtained from 1lb. is

$$\frac{33,000 \times 60}{42{\cdot}5 \times 778} = 60 \text{ B.Th.U.}$$

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

QUESTIONS.

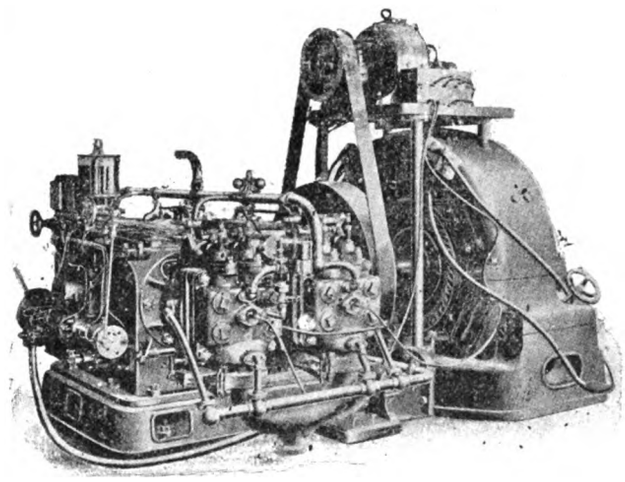
736. A shunt-wound generator is running at 440-500 volts. It is found, upon the shunt field circuit, which is separately excited, being made to the 'bus bars, a series of flashes occur midway between the commutator bars, where the conductors are joined, and the bearing surface of commutator—in other words, between the insulating varnish and air-space of the bars. This takes place immediately the shunt field or magnet coils are excited, and periodically while running on load; also, again, on breaking the shunt circuit. The armature in question was thoroughly cleaned and repainted, so it is no question of carbon or copper dust, neither is it due to oil, etc. Note that the sparking takes place between adjacent coils. Yet the generator is able to run without any undue heating, and a good insulation resistance to earth is obtained. Give what you consider the probable cause of this.—J. AINSCOUGH.

ANSWERS.

Question No. 726.—On Aug. 8 the North-Eastern Railway Company commenced an electric autocar service between Scarborough and Filey, and the other day I had the pleasure of a trip by it. The car generates its own current. A gas or petrol engine drives two dynamos, one for power the other for lighting. I didn't notice any accumulator. Can anyone furnish me with a full description of the above and discuss the advantages of converting the gas-engine power into electrical power.

Answer to No. 726 (*awarded 7s. 6d.*).—One railway after another is recognising the advantages attached to the employment of motor coaches actuated by light engines of moderate power for coping with the light traffic on their less important lines. The self-propelled petrol electric coach recently built by the North-Eastern Railway Company forms the subject of a very successful and interesting experiment. These coaches have gone successfully through an extensive series of trials, and are now running in regular service between Scarborough and Filey. The car is of the ordinary saloon type, it runs on two four-wheel bogie trucks, and measures 52ft. over the headstocks with an inside width of 7ft. 11in. It is divided into three compartments—the forward one being the engine-room, the centre part is devoted to the passengers, and the rear compartment contains the necessary controlling apparatus for driving the car backwards. Between the engine and the passenger compartments there is a gangway to permit of entrance to either compartments. Seating accommodation is provided for 52 passengers, and consists of two rows of reversible seats upholstered in the companies' usual style, situated on either side of a central gangway. The windows are provided with curtains, and the floor is laid with linoleum. The lighting arrangements consist of 24 16-c.p. incandescent lamps supplied with current from a battery of accumulators slung under the centre of the car and a small dynamo machine, which will be referred to later. The head and tail lights are also electrically fitted. The car is fitted with the usual buffers, coupling arrangements, chains, etc., and can therefore be easily used as ordinary rolling-stock.

The propelling mechanism consists of a four-cylinder petrol engine direct coupled to an electric generator, which supplies the current to two tramway motors which actually propel the coach. The engine, which was made by the Wolseley Tool and Motorcar Company, consists of four horizontal cylinders overhung on a stoutly built cast-iron crank chamber, with inspection covers above and an oil-trough beneath it. The valves of the engine are operated from two cam shafts, one on each side of the engine, driven by spiral gear and lay shafts from the crankshaft; the inlet valves are also mechanically operated. Forced lubrication is used throughout, and the engine is provided with a very efficient silencer slung under the coach, and a pipe is carried up through the roof, but as the exhaust is invisible, the coach appears to the casual observer just like an ordinary one. The crankshaft, which is "two-throw," and made of Vickers-Maxim cast steel, carries a truly balanced 3ft. flywheel. The engine cylinders and valve boxes are water-cooled—a Clarkson radiator and a Blackman fan are employed for the cooling water. The engine is governed on the throttle, but auxiliary hand throttling gear is provided, which enables the driver of the coach to accelerate the engine from either end. The ignition is on the high-tension system, with accumulators and a specially designed commutator. The fuel used is petrol of density about 0·725, and as the engine only uses one-tenth of a gallon per brake horse-power hour, and water is only used for cooling the cylinders, sufficient fuel and water can be carried for a full day's run. The total weight of the engine is 35cwt., and develops, at its normal speed of 400 revolutions per minute, 92 h.p., but when accelerated to 480 revolutions per minute (for starting quickly) it gives over 100 h.p. The dimensions of the cylinders are 8½in. diameter and 10in stroke. The engine, having four cylinders, is very well balanced, and runs extremely quietly, so that travelling in the coach is as pleasant as in an ordinary train.



This Illustration shows the Engine and Dynamo after being tested in the Wolseley Company's Works, which accounts for the irregularity of the piping and the cables.

The engine is direct-coupled to a six-pole Westinghouse generator, which is of the compound-wound direct-current type, and is of 55 kw. capacity. It is separately excited, and has been specially designed for working over a range of voltage from 300 to 550. The machine is supported on an extended bedplate, the armature being pressed on to the extended engine shaft, which is furnished with a flanged coupling between the engine and the generator. The field of the generator is split horizontally so that the upper part can be removed through an opening in the roof, provided with a movable cover so that the armature and field coils can be readily inspected. The exciter is a 3·75-kw. standard 72-volt, shunt-wound, belt-driven, multipolar generator. It is mounted on top of the main generator, and is driven by a belt from the flywheel of the latter. The function of this machine is to supply the exciting current to the main dynamo, and also the current to 30 72-volt 16-c.p. incandescent lamps. Arrangements are made whereby the voltage of this machine can be raised to 95 volts for charging the accumulators when not required for lighting.

Two Westinghouse No. 56 55-h.p. standard railway motors with single-reduction gear, ratio 13 to 64, are mounted on the front bogie by means of a nose suspension bar, with spring attached to the bogie frame. These motors are series wound, and are of the standard type usually employed for operating heavy high-speed tramcars. The controllers are the standard series-parallel tramway type arranged for electric breaking. Resistances are provided in connection with the controllers for gradually increasing the voltage of the motors at starting and for graduating the electric brake in stopping. These resistances are carried underneath the car. The engine compartment contains, besides the motor and generator, the petrol tank,

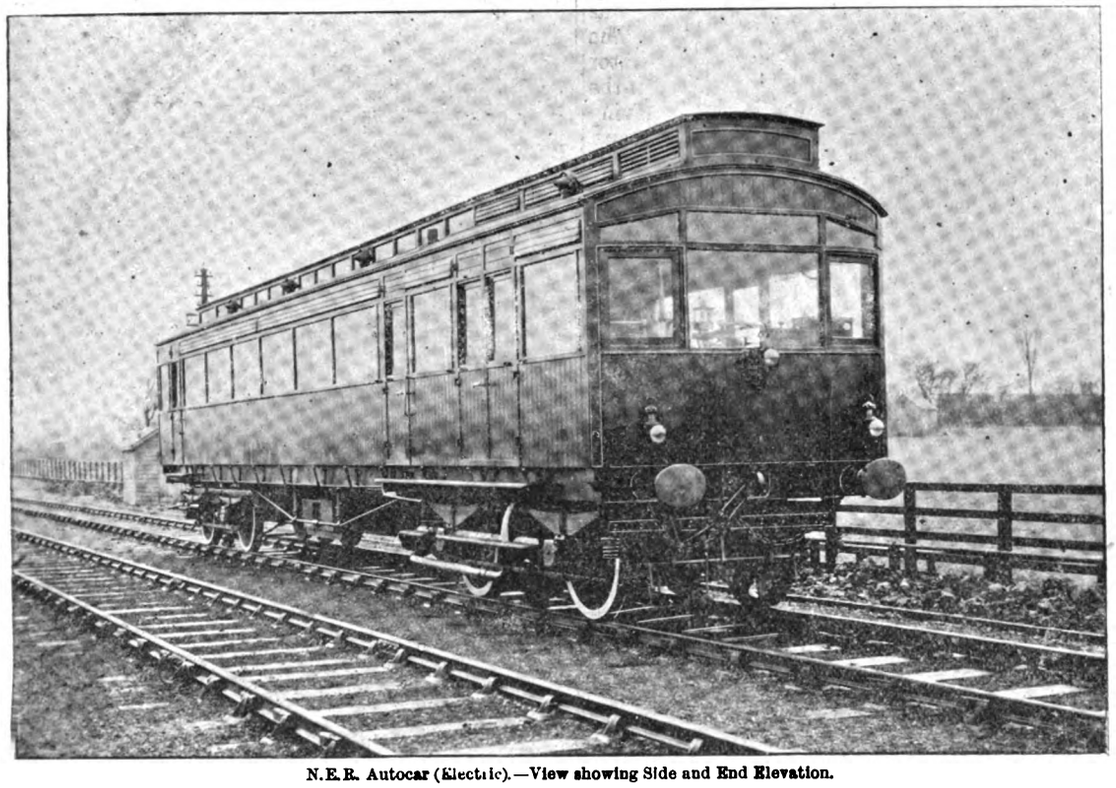
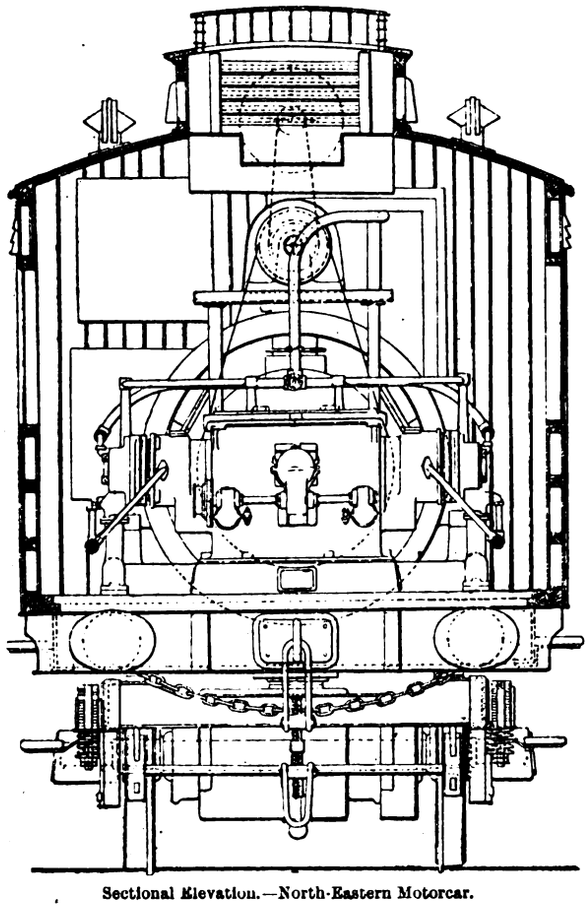
water-tank, radiator fixed in the roof, fan to induce a draught through the radiator driven by a belt from a pulley on the armature shaft of the exciter, the main switchboard, and one of the controllers already adverted to. The storage battery consists of 38 cells in ebonite jars assembled in a wooden box suspended beneath the car. Each battery has a capacity of 120 ampere-hours.

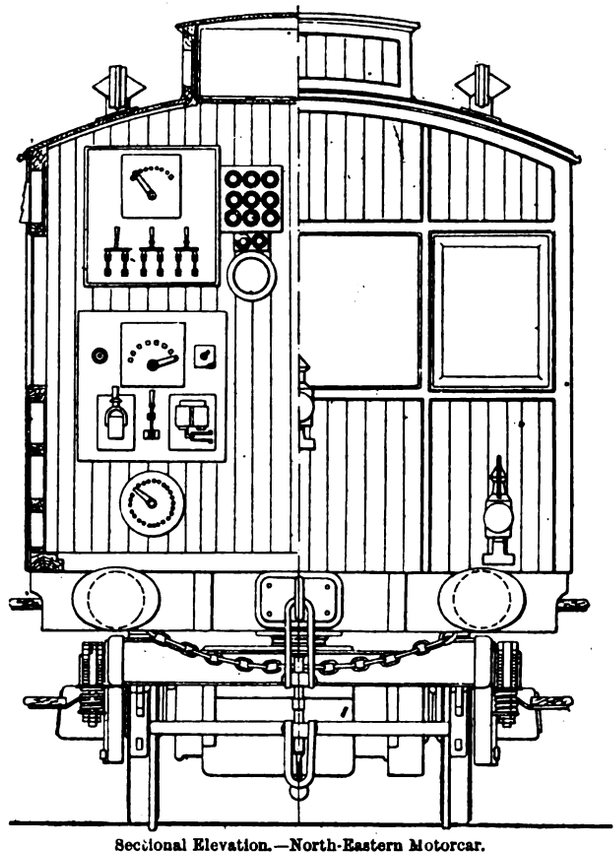


N.E.R. Autocar (Electric).—View showing Side and End Elevation.



Sectional Elevation.—North-Eastern Motorcar.

An air compressor is located on the rear bogie, and supplies air for the Westinghouse air brakes, and also for blowing an alarm whistle. It is driven by a 1-h.p. electric motor, which is automatically switched on and off by switches controlled by the pressure in the air reservoir, thus maintaining a constant pressure in the latter. Besides the air brakes, the coach is fitted with special electric brakes. These brakes consist of two electromagnets suspended beneath the wheels of each truck and immediately above the track rail. These magnets are so arranged that the magnetic circuit is completed through the rail, so that when the coils are energised the magnet is attracted to the rail, thus causing friction between the



Sectional Elevation.—North-Eastern Motorcar.

magnet and the rail, so retarding the car. The downward motion of the magnet also causes brake blocks to press on each of the wheels, thus further retarding the motion, and the two together can bring the car to rest in a very short

Digitized by Google

distance. The brake coils are energised by the motors acting as generators, thus further increasing the braking power, and also making the brake perfectly reliable, as it does not depend upon the generator plant for the supply of power. The whole of the electrical equipment was furnished by the British Westinghouse Company. The method of working is somewhat as follows: The generator is used as a motor at a reduced speed supplied from the accumulators for starting the petrol engine. After having brought the engine up to speed, the pressure of the generator is adjusted to 400 volts by means of a rheostat in the field circuit, and the car started in the usual way by manipulating the handle of the series-parallel controller to series point for slow speed and to the multiple point for high speed. Afterwards the voltage of the generator is gradually raised to 550 volts by means of the field rheostat, and at this pressure the car will attain a constant speed of 36 to 40 miles per hour. To stop the car, the controller is turned to the "off" position and then over the braking points, thus applying the magnetic track brake. As soon as the car is stopped the generator voltage is again adjusted to 400 volts, when it is ready for starting. It will be seen that the speed is varied by varying the voltage of the generator at two points—namely, approximately half speed and full speed.

As regards the second part of the query, many people at first glance are not able to see why petrol motors should not drive the railway coaches in much the same way as they are employed to drive a motorcar, and why there has been any need to introduce the apparent complication of electrical transmission. The reason is this, that the effort required to propel a vehicle along rails is so very much less than that required to attain the same speed on the road (the average resistances as given by various authorities are: railway track, 8lb. to 10lb. per ton; turnpike road, 50lb. to 500lb. per ton). Hence railway coaches can be used which are proportionally heavier compared with the power of the engine than are motorcars. But while the power required to maintain the speed is less, the effort required to start the railway coach is proportionally greater with its increased weight, and consequently some form of variable transmission which is capable of producing extreme torque as well as extreme speed is essential. And this is provided in a highly practicable form by electric transmission using the series-parallel control system. This system gives very rapid acceleration at starting, and constitutes one of the chief advantages of the petrol-electric system over the self-propelled steam coaches.

The motor coaches when first equipped with the Wolseley motor were provided with a battery of accumulators to help the dynamo when starting the motors; but these were found too heavy, and the dynamo has now been rewound so as to be capable of giving the increased amount of current required for starting by itself, so that the main battery is no longer required and has been entirely discarded, and now only the small battery already averted to remains. These cars can be put in service in 10 minutes, can be driven from either end with equal facility, and can successfully negotiate any gradients on the company's system. The weight of the coach in full running trim is 35 tons.—H. E. H.

Answer to No. 726 (*awarded* 7*s.* 6*d.*).—This system of car propulsion, although new in its application to railway work, has been for some years in use on heavy road vehicles, such as omnibuses, and is known as the Fischer system. It consists essentially of a petrol engine driving an electric generator at constant speed, the car itself being propelled by electric motors deriving their current from the aforesaid generator. In the North-Eastern Railway equipment the petrol engine, which is supplied by the Wolseley Tool and Motorcar Company, of Birmingham, is of the four-cylinder horizontal type with two cylinders placed on each side of the crank chamber, a vertical engine having been found unsatisfactory for this purpose. The cylinders are 8½in. in diameter, with stroke 10in., and at normal working at a speed of 420 revolutions per minute the engine develops 80 b.h.p. The speed can, however, be increased to 480 revolutions per minute by hand regulation when it is required to get under way quickly. The flywheel used is 3ft. in diameter, and the rim is about 6in. wide and 4in. thick. The engine is coupled to 55-kw. six-pole direct-current generator design to work sparklessly between voltages of 300 and 550, and is separately excited by a small 3¾-kw. shunt-wound, four-pole machine, belt-driven from the flywheel at about 1,000 revolutions per minute. This exciter is wound for 72 volts, but this may be increased to 95 for the purpose of charging a battery of 38 secondary cells situated under the car body, and which do the lighting of the car when it is running. After what has already been described, the usual equipment of parallel-series controller and standard motors have been installed so that an ultimate speed of 36 miles per hour is attained on the level track. Advantage has, however, been taken of the fact that the generator is on the car, and a separate regulating rheostat has been inserted in the field circuit, so that its voltage is reduced to the lower limit when starting, thus wasting less energy in cutting down the current.

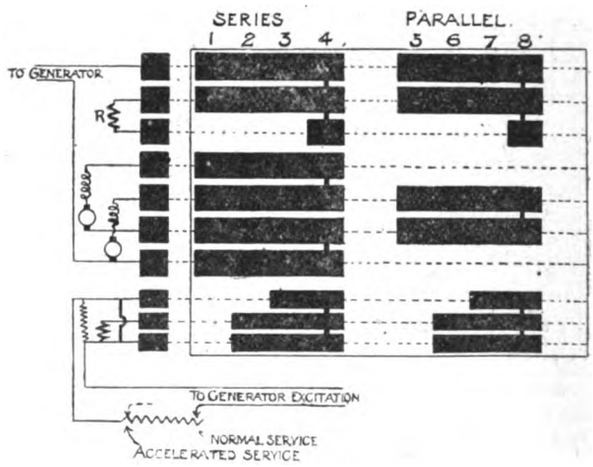


FIG. 1

The claims which may be put forward for this system are all the *advantages* of the oil-engine over the steam-engine and the elimination of the *disadvantages* of the direct-driving oil-engine by the use of the intermediate electric generator and motors. These are in the first case (1) the absence of a boiler and the attention it would require, the feeding of fuel into the oil-engine being automatic, and (2) the better thermal efficiency of the small gas-engine compared with the small steam equipment; and in the second case: (1) the oil-engine running always at a constant speed, thus giving out its power most economically at that time, at which otherwise it would be most inefficient—that is, at the time of starting; (2) the elimination of difficulties in the matter of clutches for connecting the motor to the axles at starting—the clutch being represented in this system by the electric controller; and (3) further economy at starting, as already pointed out, by reducing the voltage. An arrangement of a controller for dispensing with the use of the auxiliary rheostat at starting is shown in the figure. It will be noticed that the excitation is always on the generator, but when the car is not running the lowest voltage is being generated. On the second and third positions resistance is cut out of the generator field circuit, and on the fourth, the full series running position, the car is running at full voltage and with all resistance cut out of the main circuit between generator and motors. As already mentioned, accumulators are provided, but are used for lighting only. On omnibuses and other heavy vehicles on which the system has been used, and on which the voltage used is much lower (of the order of 80), sets of secondary cells are provided to run in parallel with the generator, and thus take the peak of the load at starting and allow a smaller equipment to be installed than would otherwise be necessary.—Z. Y. X.

[Other replies to Question No. 726 will be given in our next issue.—ED. *E. E.*]

ANSWERS.

Question No. 726.—On Aug. 8 the North-Eastern Railway Company commenced an electric autocar service between Scarborough and Filey, and the other day I had the pleasure of a trip by it. The car generates its own current. A gas or petrol engine drives two dynamos, one for power the other for lighting. I didn't notice any accumulator. Can anyone furnish me with a full description of the above and discuss the advantages of converting the gas-engine power into electrical power.

Answer to No. 726 (*awarded* 7*s.* 6*d.*).—The petrol engine made by the Wolseley Tool and Motorcar Company, of Birmingham, which drives the North-Eastern Railway coach, is of 80 h.p., having four cylinders, 8½in. bore, 10in. stroke. The dynamo driven by this engine generates the current for the motors, the petrol engine being controlled by a governor working on the admission.

Now, as to the discussion regarding converting the gas-engine power into electrical power, I will presume the writer means the advantages there are in driving by the above method over other methods. I will take three ways of transmitting the power to the wheels: (1) by gearing, two or three speeds being required, and the engine thrown in at starting by either a magnetic or other friction clutch; (2) by the method used on the North-Eastern Railway coach; (3) by a direct drive from the engine to wheels of the coach (this is the Denn speed gear, illustrated in the *Autocar* of Sept. 17). The change of gear is brought about by the connecting rods having a variable throw. To weigh the advantages of these methods is not an easy matter.

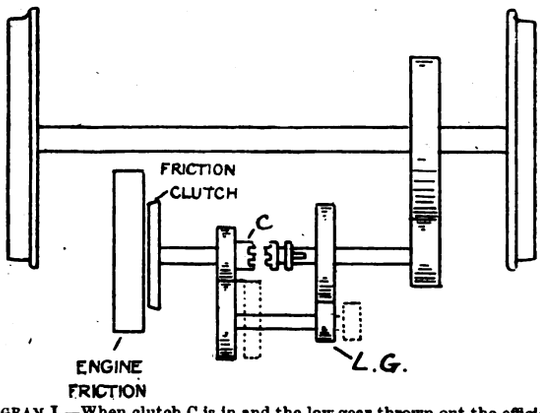

DIAGRAM I.—When clutch C is in and the low gear thrown out the efficiency is 85 per cent. With low gear in it is from 50 to 60 per cent.

Diagram 1 is a rough sketch of the most economical form of gear drive, and (2) gives an approximate idea of the Denn gear. Some details of it may not be quite correct, but the working of it is the same.

The following table gives the efficiencies.

	Efficiencies, per cent.		
	During acceleration and full load.		Normal load, say, 20 per cent. of full load.
No. 1. By gearing	50 to 60 (low gear)	...	85 (high gear)
No. 2. N.E.R. method..	75	...	85
No. 3. Denn gear.....	75	...	80

From this we see that the gearing is, taking all round, the least efficient (50 to 60 per cent. is from tests), and there is little difference between the others. The electrical method may be higher than I have put it in both columns, but the resistance when starting would bring the figure down; also the 85 per cent. in normal load column is also I think high, especially when running light, and the load on the level would be less than 20 per cent.

Now, as regards the Denn gear, if the connecting rod or coupling rod was like the locomotive, nearly all the power would reach the wheels, and on the high gear it is almost the same when C approaches D (see diagram 2). In this case the efficiency entirely depends on the clutch—a roller clutch is used in this gear—and not more than 20 per cent. ought to be lost in this. On the low gear there would be little difference. I have mentioned this gear because it must be better than the train of gearing now generally applied to traction work, and probably will be used for certain work in the future.

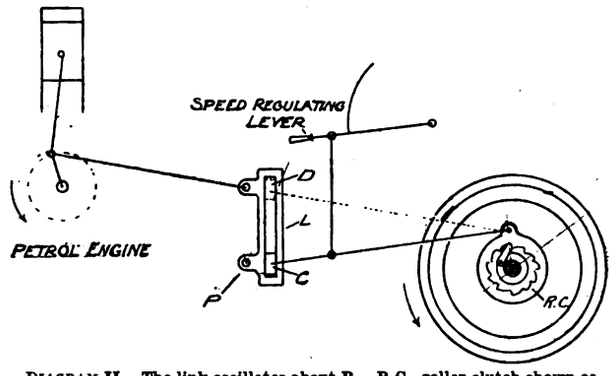

DIAGRAM II.—The link oscillates about P. R.C., roller clutch shown as paul and ratchet.

In further favour of the petrol engine for use on railways, the Wolseley Company have just secured an order for a six-cylinder engine of 140 h.p. from the General Electric Company, of Schenectady, N.Y., for the first of their petrol engine coaches. It is not impossible that the locomotive may be gradually superseded by the more economical gas-engine when a suitable gear or combination of cylinders is used. This same company are building a small shunting locomotive of 24 h.p., the engine being covered by a bonnet of the outline of a tank engine, and the vent of the silencer takes the form of the locomotive funnel (*Autocar*, Sept. 17). I have not touched on the possibilities of the pneumatic system (compressed air transmission), the efficiences of this system being uncertain.—J. ARNOLD.

Answer to No. 726 (*awarded* 5*s.*).—The self-contained autocars used on the North-Eastern Railway are 52ft. long over all, and are divided into three compartments. The front one contains the petrol motor-driven generator, switch, and other controlling and braking gear for driving the car from this end. The centre portion of the car is for passengers only, and the third (or end) portion contains the necessary controlling and braking gear for operating the car from that end. The generating plant consists of a 80-h.p. four-cylinder horizontal Wolseley petrol motor, running at 420-480 revolutions per minute. All the valves are mechanically operated by cams from a worm-driven cam shaft. The cylinders and valve boxes are water-cooled, and forced lubrication is employed where possible. This petrol motor is direct-coupled to a 55-kw. separately-excited compound-wound generator, designed to work over a wide range of voltage—*i.e.*, from 300 to 550 volts—with the normal speed of the engine 420 revolutions per minute. A small shunt-wound exciter is fixed above the main generator, and is driven by belt from the engine flywheel; its capacity is about 4 kw. at 72 volts, and is used, in addition to exciting the main generator, for car lighting, and by increasing its voltage for charging a battery of 38 cells suspended under the car. The storage battery supplies current for running the generator as a motor for starting up the petrol engine, also for car lighting when required.

We now come to the driving gear proper. This consists of two 55-h.p. Westinghouse series-wound traction motors, suspended in the usual way on the forward bogie, geared to the running wheels by single-reduction gearing. The controllers are of the ordinary series-parallel control type, with rheostatic braking notches. In working the generator (which is kept running when once started for the day), voltage is adjusted by a rheostat in the field circuit to 400 volts; the car motors are then started up in the usual way. The generator voltage is then gradually increased to 550 volts, at which pressure the car will rapidly speed up to 36 miles per hour. A small motor-driven air com-

Digitized by Google

pressor supplies air for blowing a hooter or alarm whistle. Although this method of working seems a very inefficient and a roundabout way of obtaining power, the advantages gained more than compensate for the loss in efficiency that could be obtained by more direct means. As this double conversion of power is the only way of obtaining electric motive power, with the exception of external sources or a heavy and troublesome storage battery, it must be used.

The advantages are as follows: (1) the operation and control of the car is more convenient and effective by using electrical power; (2) more rapid and smooth acceleration is possible than with either steam or petrol motors direct, and for runs with many short-distance stops this is a most important point; (3) various economical rates of speed can be easily and quickly arranged; (4) the car can be driven from either end and in either direction. It will be seen from the above that the method of driving described has many advantages that would be almost impossible by using either steam or oil engines direct. For further particulars the reader is referred to the *Electrical Engineer* for April 17, 1903.—MAGNUS H. VOLK.

Question No. 727.—State how to enter the navy as an electrician, the duties of same, and the prospects.

Best Answer to No. 727 (*awarded* 10*s.*).—The post of electrician in the Royal Navy is open to all able-bodied young men, of good character, who have had experience as fitters in electrical shops. Candidates must be between the ages of 21 and 28, have a chest measurement of 32in., and stand 5ft. 3in. in height, although *specially* desirable candidates *may* be received under that standard. The height measurement is taken without shoes, and the chest measurement without clothes. Candidates should ascertain whether they come up to these requirements, and should, as a rule, apply by letter, before incurring travelling or other expenses in proceeding to a recruiting office.

Conditions of Entry.—The "King's Regulations and Admiralty Instructions" contain the terms and conditions under which men accept service in the Royal Navy. Candidates are entered as acting electricians, and are required to sign an engagement on entry to serve for 12 years' continuous service. After a course of training in a torpedo school, they are, if found duly qualified by conduct and abilities, confirmed in the rating of electrician, fourth class.

Medical Examination.—All candidates before being accepted are subjected to a strict medical examination by naval medical officers, and are required to be free from any physical defect or disability. The recruiting officer arranges for a provisional examination, when necessary, by a local medical officer at Government expense. Candidates who are accepted by the recruiting officer are sent free of cost to a naval depôt or training ship for an educational examination. Candidates are examined for entry on board the H.M.S. "Vernon" at Portsmouth and H M.S. "Defiance" at Devonport. Those for the Chatham Port Division are at present examined and trained on board the "Vernon."

Nature of the Educational Examination —The examination consists of three sections—viz., general education, theoretical technical, and practical technical. The first comprises a general education equivalent to the sixth standard in a Board school—that is, vulgar and decimal fractions, simple interest, dictation, and reading. The theoretical part of the technical examination consists of questions on the general construction of electrical apparatus, instruments, motors, etc., simple testing, etc. The practical part requires ability to perform the following jobs, etc.: relining and adjusting bearings; using a lathe, screw-cutting test for bolt and nut; repairs to any part of electrical apparatus, instruments, motors, etc. Candidates provisionally entered but rejected at the final examination are granted free passes to their homes.

Rates of Pay.—The rates of pay (besides provisions) are given below. Men are paid weekly at home and monthly abroad. Men re-engaging after completing the time for a pension receive 3s. 6d. a week extra: Electrician—On entry as fourth-class electrician, 38s. 6d. a week; advancing to third-class electrician, 40s. 3d. a week after three years' service; advancing to second-class electrician, 42s. a week after seven years' service; advancing to first-class electrician, 45s. 6d. a week after 12 years' service. Chief electrician—Second-class chief electrician, 49s. a week, advancing to chief electrician, first-class, after six years' service in the preceding rating, 52s. 6d. a week.

Messing.—A free ration is given, including 1lb. of meat, etc. For any portion not taken up "savings" are paid, with which relishes can be bought at the canteen. If not provisioned, men are given allowances of 1s. 1d. to 1s. 6d. a day in lieu. Chief electricians and electricians mess with the chief petty officers.

Allotments.—Great facilities are given for allotting or remitting money to families and friends free of expense; besides this, savings banks are established on board his Majesty's ships, and at the principal home dockyards, in which interest on deposits (3¾ per cent.) is paid by the Government.

Allowances towards Outfit —On entry and again on engaging to complete the time for pension (22 years), electricians receive £3. 10s. towards the cost of the outfit which they have to obtain, and £1 for bedding, subject to certain conditions specified in the "King's Regulations."

Medical Attendance.—Medicines and hospital treatment, both at home and abroad, are provided at the Government expense. In cases requiring it, treatment in a naval hospital is allowed, full pay being continued for three months, with a slight deduction after the first 30 days.

Leave.—Leave on full pay is allowed both while serving at home and on return from foreign service. This leave, after a full term of foreign service, amounts to six to eight weeks.

Gratuities.—Gratuities for good conduct, ranging from £5 to £15, are given to continuous-service men on being pensioned.

Pensions.—Life pensions of over £1. 1s. a week will be granted after 22 years' service with very good character; for each additional year of such service £2. 5s. 7d. a year extra pension will be given. Electricians are, if physically fit, allowed to remain in the service till they reach the age of 50 years. Men invalided for disability contracted in the service receive gratuities or pensions proportional to the length of service and conduct. Men incapacitated for duty by injuries or disabilities attributable to the service receive special consideration. If men are killed on duty, pensions will be given to their widows and allowances to their young children, who may also receive educational advantages.

Good Conduct Badges.—These badges, of which three may be obtained, are, in the case of electricians, as far as weekly pay is concerned, honorary, but reckon for an increase of pension.

Position.—Electricians are classed as chief petty officers, a position which carries with it many privileges.

Duties —These consist chiefly in the care and maintenance of the electrical apparatus on board, which differs little from an ordinary land installation.

Promotion.—Electricians on the completion of eight years' service, of which five must be at sea, are eligible for examination for advancement as vacancies occur in the rating of chief electrician.

Uniform.—The uniform worn by this rating is detailed below. Chief electricians wear three buttons on each sleeve of long jacket; all others wear an opening at the cuff with two small gilt buttons. In undress, the long jacket is made of blue serge or duck, single breasted; trousers of blue serge or duck. Long jacket—blue cloth, double breasted; monkey jacket—thick cloth, similar to above as an overcoat; white drill tunic, for hot climates; trousers—blue cloth or white duck; waistcoat—blue cloth, single breasted; cap—blue cloth with peak and device of crown and anchor in gold on purple ground; buttons—gilt, uniform.

For further information apply to the Royal Marine Recruiting Staff Officer, at 7, Whitehall-place, London, S.W., or to the Captain, Royal Naval Torpedo School, Portsmouth or Devonport.—H. E. H.

Answer to No. 727 (*awarded* 7*s.* 6*d.*).—The conditions laid down by the Admiralty for the entry of electricians into H.M. Navy are as follows. The candidates shall be able-bodied young men of good character. They must have had experience as fitters in electrical shops. The age limit of entering is from 21 to 28, and the candidates' stature should be 5ft. 3in. in height with 32in. girth of chest, but if the

Digitized by Google

candidate is such as is specially desirable for the service, this standard may be lowered. Before he can be entered the candidate must pass a twofold examination—viz., education and practical work. The education comprises arithmetic, dictation, and reading; the arithmetic including vulgar and decimal fractions and simple interest. The practical consists of such work as relining and adjusting bearings, repairs to electrical apparatus and instruments, metal-turning and screw-cutting on a lathe.

The successful candidate enters the service as a chief petty officer, and the scale of pay is as under: on entry, 38s. 6d. per week; after three years, 40s. 3d. per week; after seven years, 42s. per week; after 12 years, 45s. 6d. per week, also free navy rations. After eight years' service he becomes eligible by examination for advancement to chief electrician, and is rated as vacancies occur. This scale of pay is: under six years as chief electrician, 49s. per week; after six years as chief electrician, 52s. 6d. per week, with free navy rations. As electricians are chief petty officers from date of entry, their service counts for increase to pension, and they can get as much as £1. 1s. per week after 22 years' service, and may increase such pension by £1. 10s. 5d. a year for each subsequent year served with good conduct up to the age of 50. The foregoing I have copied from a book which can be had at any of the naval recruiting stations.

Now, regarding their duties. To be brief, the electrician has to keep in working order and to do the ordinary repairs (the big items being relegated to the dockyards) to lighting circuits and fittings, motors and circuits, bells, telephones, etc., and holds himself directly responsible to the naval lieutenant told off for torpedo and electrical duties. The dynamos on a modern British battleship comprise four, each of about 50 kw. (the total output not being so great as in some of the foreign navies or the ocean liners). All the circuits, fittings, etc., are on the watertight two-wire principle; further detail does not come into the question. Applications from a distance can be directed to "The Captain, the Royal Naval Torpedo School," or to "The Commander, the Naval Recruiting Office," either at Portsmouth or Devonport. There is a notice in the recruiting office to the effect that there are no vacancies at present.—WILLIAM BEARD.

Answer to No. 727 (*awarded* 7*s.* 6*d.*).—The following particulars, which may prove useful to "H. W. H.," are extracted from the pamphlets which are issued by the Admiralty as a guide to prospective candidates on how to join for service in the Royal Navy.

Electricians.—Able-bodied young men of good character, with experience as fitters in electrical shops. Age, 21 to 28 years; girth of chest, 32in.; height, 5ft. 3in., but specially desirable candidates under that standard may be received.

Nature of Examination.—Educational: sixth standard—vulgar and decimal fractions, simple interest, dictation, and reading. Practical: relining and adjusting bearings; repairs to electrical apparatus and instruments; metal-turning and screw-cutting on a lathe.

Candidate's Entry Form.

.....
.....} Full address.

.....(Date).

I am desirous of being considered as a candidate for entry in the Royal Navy.

I wish to enter as .....(state rating).

My age is.....years.....months, and my height is.....ft.....in., and chest measurement.....in.

I can satisfy the educational and medical requirements, and give satisfactory references as to my character.

Please send me directions how to proceed.

.....(Signature.)

To the Admiralty Recruiting Officer,

.....

[Address of officer for electrician rating:
Captain, Royal Naval Torpedo School,
Portsmouth or Devonport.]

Pay and Position.—Electricians are entered as chief petty officers, a position which carries with it many privileges. The pay is as follows: As electrician—pay on entry, 38s. 6d. per week; after three years, 40s. 3d. per week; after seven years, 42s. per week; after 12 years, 45s. 6d., and free rations. As chief electrician—under six years as chief electrician, 49s. per week; after six years as chief electrician, 52s. 6d. per week, and free rations. After eight years' service they become eligible by examination for advancement to chief electrician, and are rated as vacancies occur. £4. 10s. is allowed on entry towards cost of outfit. Pensions to chief electricians and electricians: as electricians are chief petty officers from date of entry, they can get as much as £1. 1s. a week after 22 years' service, and may increase such pension by £2. 5s. 7d. a year for each subsequent year served with very good conduct up to the age of 50.

A short time ago an Admiralty recruiting officer stated to the writer that a candidate for the rating of electrician must be a fitter and turner, and possess a thorough working knowledge of the art of screw-cutting. If necessary, the candidate would be given an electrical training after joining the service.—S. L.

Question No. 728.—A house wiring specification calls for all casing under floors to be "half mitred and screwed." Give particulars, with sketches, of requirements, mentioning any other method ensuring a firm and workmanlike job.

Answer to No. 728 (*awarded* 7*s.* 6*d.*).—The specification in question calls for casing to be half mitred, which I take to mean a half-lap mitred joint. Fig. 1 shows two

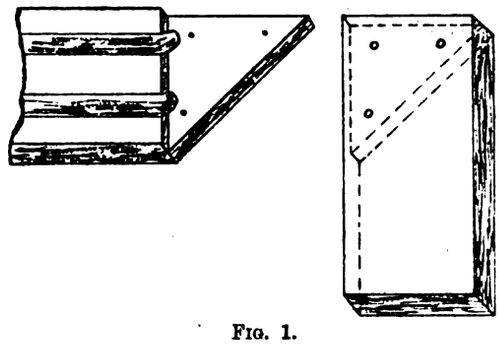

FIG. 1.

pieces of casing at right angles to each other, ready for jointing. By the above method you can make a strong job, because you can screw the half-lapped parts together. When two pieces of casing meet as shown in Fig. 1, one piece will be laid across the joists, and the other between two joists. The length between the joists will have no support, only at the ends that are screwed,

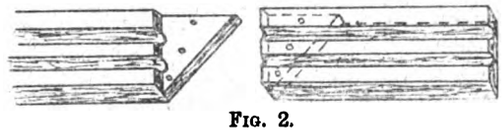

FIG. 2.

therefore a stemming piece should be fitted between the joists at intervals of about 6ft. or 8ft., to support the casing and keep the strain off the joints, which are half-lap mitred. Fig. 2 shows two pieces of casing ready for jointing, to form one length; you can also screw these half laps together. By this method you can save a lot of short pieces of casing, because if this method is not adopted you have to joint your casing in the middle of a joist, allowing

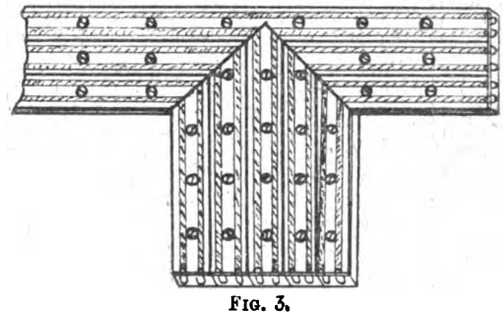

FIG. 3.

each length to come half-way on to the joist. This method no doubt takes up a lot of time. The capping in this method should be mitred in the ordinary way and screwed down. Where casings are run on the surface they can be made to look neat if they are half-lap mitred or mitred, and the capping mitred as shown in Fig. 3. Where casings have to cross each other on the surface, a bridge piece should be cut and

Digitized by Google

screwed on, as shown in Fig. 4. This prevents the wires crossing each other. A very good way of jointing casing under floors is to mitre each length and joint them on a joist so as to get a screw or nail in each end, and the lengths which go between the joists should be left long enough to get a screw through the two casings, and so keep the strain off the wires In places where the wires go through fireproof walls or floors, or where they might be subjected to water, iron pipe should be passed through to carry the wires, and after the wires are drawn in and the casing fit close to the end of the pipe, the ends should be sealed up with magnesia cement. Some architects won't allow the joists to be cut up for casing, and in some cases holes are bored through each joist to allow the wires to pass through, then casing is fixed on the wires between each joist and allowed to hang on the wires. This is not a satisfactory job at all. In cases

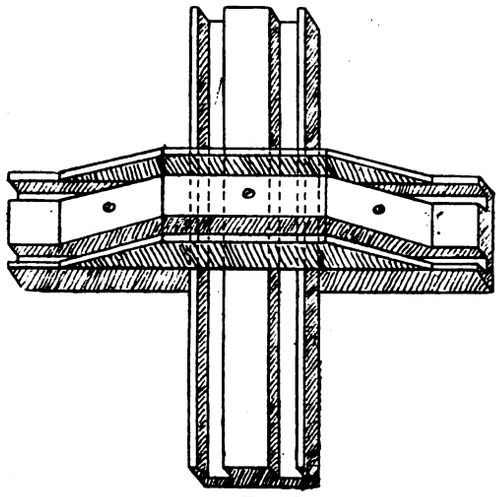

FIG. 4.

where the joists are not allowed to be cut for casing, tubing or conduits should be installed with plenty of inspection pieces, which makes a very strong and reliable installation, and does not require so much cutting of the joists. In an installation of this description, loop wiring, and split up into circuits, is the best method; thus you will have no joints whatever.—J. P. S.

Answer to No. 728 (*awarded* 7*s.* 6*d.*).—To half mitre casing is very unusual, the idea is to more completely "break" the joint. Half-mitred joints, though seldom employed by the wiremen, are well known to the carpenter, and require some little care in fitting to ensure a good job. A half-mitred right-angled joint in casing is

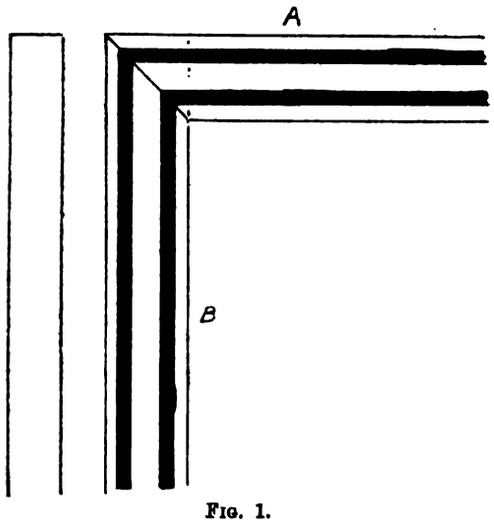

FIG. 1.

shown in Fig. 1. In order that the joint may be the more easily understood, Fig. 2 shows two views of *a*, and Fig. 3 two views of *b*. Fig. 4 is a half-mitred straight joint, *b* is cut the same as *b* in the right-angled joint, but *c* is cut rather differently, as shown in Fig. 5. It will be seen that although the joint is better covered, parts of the casing are so cut that they are very weak. Most engineers are satisfied with an ordinary mitred joint.

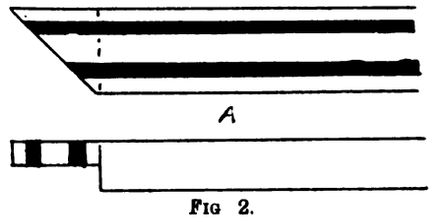

FIG 2.

It is good practice in any case never to make the joint in the capping over that in the casing. Casing should always be screwed in preference to being nailed. Where nails are

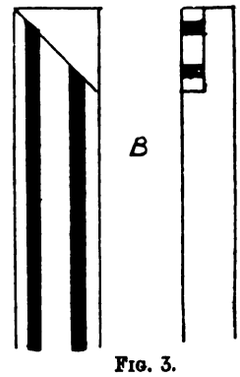

FIG. 3.

used the main consideration is cheapness. When casing is run under floors, it should be so let into the joists that it comes under the middle of a board. If casing is run under

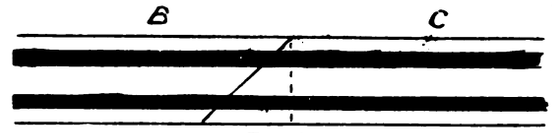

FIG. 4.

the joist between floorboards, there is great danger of water, etc., finding a road to the casing. In good work all boards over casing are screwed down. They may then easily be

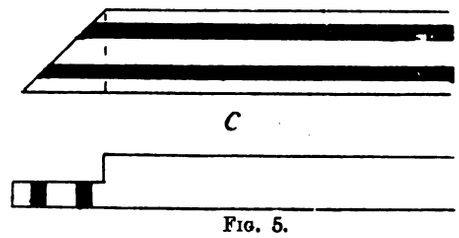

FIG. 5.

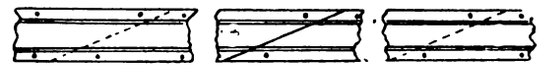
removed, if necessary, to inspect the wiring. All casing should be well painted or varnished. A thick layer of fireproof paint is also very desirable.—M. M.

Answer to No. 728 (*awarded* 5*s*).—A mitre is usually cut at an angle of 45deg. and a half mitre at an angle of 22½deg., although the latter term is seldom met with.



Presumably the idea is to use the half mitre at joints in the straight runs, so as to avoid plain butt joints. If the joints in the capping are kept well away from those in the casing, and are cut at the same angle, the capping will, if well screwed, keep the several lengths of casing well in line, and a good stiff job will be made. When the casing runs parallel with the joists, and is supported by means of strips placed from joist to joist, these strips should not be more than 5ft. apart. In the sketch three joints are shown—two in the casing (dotted lines) and one in the capping (continuous line).—A.

Supplement to "The Electrical Engineer,"
NOVEMBER 11, 1904.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

737. Describe what you consider the best method of locating a middle-wire earth in any section of a network, giving sketches of same.—READER.

738. Describe a practical way (other than by indicator card) of taking valve settings of Willans three-crank compound engine fitted with automatic expansion.—VALVES.

ANSWERS.

Question No. 729.—Much trouble has been experienced with various hand-wound armatures, on which wire of 18 S.W.G. and smaller has been employed, owing to breaking of end connections while running. The breaks always occur within ½in. of the end of the core and in the *straight* wires. Please explain the cause of the trouble and suggest remedies.

Answer to No. 729 (*awarded 7s. 6d.*).—If by "end connections" the connections to the commutator are meant, the trouble is one from which most makes of small armatures have suffered. The cause is the perpetual vibration to which the short stretches of unsupported wire forming the connections to the commutator are subjected. This vibration may be due to (1) vibration of the whole armature, due to inaccurate balancing; (2) relative motion between the armature winding and the commutator, owing to the latter being insecurely attached to the spindle—*e.g.*, by means of a single small grub screw in place of a proper key; (3) electromagnetic interaction between the current in the connecting wires and the leakage magnetic field in which they are rotating. This last cause is, however, unlikely to be present to any great extent in a small armature.

The remedy usually resorted to, generally with complete success, is the employment of thicker wires to form the commutator connections. Thus, on all armatures wound with a wire smaller than about No. 16 S.W.G., half a turn of winding at the start and at the finish of each section is cut off and replaced by a piece of larger wire (about No. 16 S.W.G.) sweated on. These thicker wires are held firmly on the core amongst the other wires by means of the usual binding bands, and their increased cross-section enables them to withstand the unavoidable vibrations much better than the smaller wires which they replace. Sometimes each end of each section, to a distance about equal to half a turn, is doubled back and twisted on itself, thus practically doubling the cross-section of the connections. Part of the double wire thus made is clamped under the binding bands, and the remainder forms the connection to the commutator.—Q.

Answer to No. 729 (*awarded 7s. 6d.*).—The wires break at a spot between the core and the commutator because they are weakest just there. The vibration which is set up when the armature is running tends to crystallise the wires at the point where they eventually break. If the commutator does not fit tight on its pin or key on the spindle there will always be a very slight relative movement between the commutator and the core, which will be communicated to the wires behind the commutator. The straight wires, being less flexible than the curved ones, naturally tend to break first. Again, the heat imparted to the wires during the operation of sweating them to the commutator segments makes the wires brittle at a point where they enter the commutator. This can be obviated by dispensing with solder and using instead small steel grub screws for attaching the wires to the segments, a practice which has become quite common on the Continent.

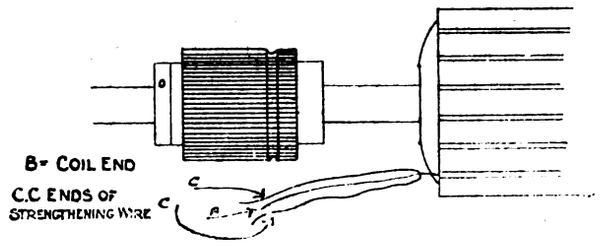

FIG. A.

The most effective remedy against these breakages is to strengthen the wires themselves. This may be effected in several ways: (1) by twisting together that pair of wires which is to be coupled to the same segment; (2) by doubling back the finishing end of each coil and twisting together the two wires of the loop thus formed; (3) by attaching "strengthening wires" to the coil ends (see Fig. A) as close as possible to the core, and twisting the three ends together and inserting them into the same segment (see Fig. B). Additional strength may be given to these twisted

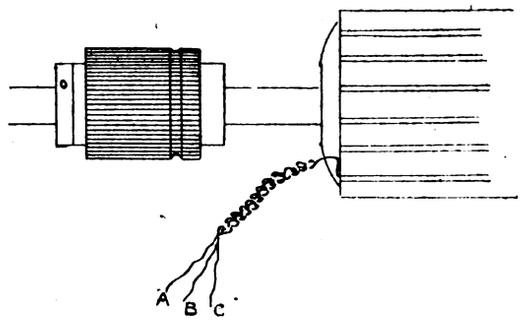

FIG. B.

wires by taping them before attaching to commutator. As the twisting by hand is a slow process, a wire twister (see Fig. C) should be used. This consists of a brass tube about 8in. long, fitted with a fibre plug of the same length driven tight inside it. Three holes about ⅛in. diameter are drilled through the fibre parallel with its axis. The armature winder inserts the three wires in these holes, and by turning the tube round, and at the same time drawing it towards himself, forms the three wires into a single twist.

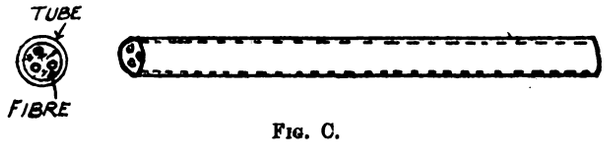

FIG. C.

If the design of the armature allows of it, a string band should be wound on over the wires between the core and the commutator. This should be done after the coil ends have been sweated to the segments, and the first turn of the string band which is nearest to the commutator should be laced over and under each successive wire. This lacing not only gives extra support to the wires, but also prevents the band from working down on to the commutator.—W. B.

Answer to No. 729 (*awarded 7s. 6d.*).—The cause of the breaking of end connections of small armatures is largely due to mechanical defects. A considerable amount of trouble was caused by the breaking of the wires of the armature of a 3-h.p. two-pole motor running at 1,300 revolutions per minute driving a scissors-grinding shop.

Digitized by Google

The general arrangement of the armature was as shown in Fig. 1. It consisted of a smooth-core ring armature. The stampings were mounted on a brass hub having an end plate fixed by means of three $\frac{5}{16}$ Whitworth screws, marked A, the hub being fixed on the shaft by a feather key. The commutator was driven by the steel pin, B, let into the brass hub and into the cast-iron bush. After the machine had been running a few weeks the armature wires began to break off. On examining the armature, it was found that (1) the screws, A, had worked loose; (2) the pin B was also loose. The above had worked loose due largely

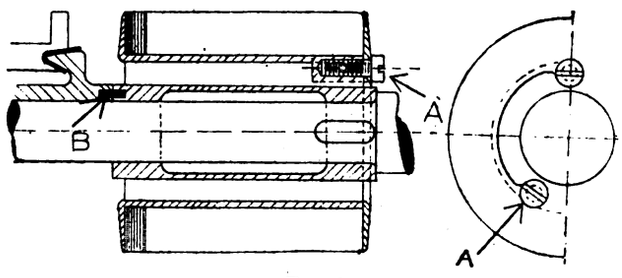

FIG 1.

to a bad joint in the belt and the grinding stones being out of balance. After the screws, A, had been replaced by steel studs screwed well home, also the commutator hub had a keyway cut in it, and a jib-headed key fitted, and also a good joint was made in the belt, the troubles entirely ceased, and the machine has now been running $3\frac{1}{2}$ years without having any further breaking of end wires, showing that it is due to mechanical and not electrical faults.—C. G.

Answer to No. 729 (*awarded* 5*s.*).—The cause of the trouble which "A. B. D." is experiencing is probably due to vibration in the connections between the armature and the commutator, owing to the conductors not being held

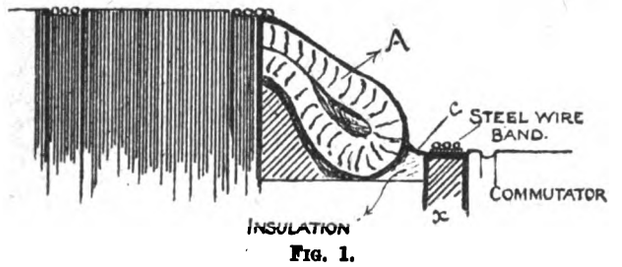

FIG. 1.

down securely by steel-wire bands. On small armatures it is important to have the commutator connections as short as possible, and also to have a firm support for them to rest on. In Fig. 1 the armature winding and commutator

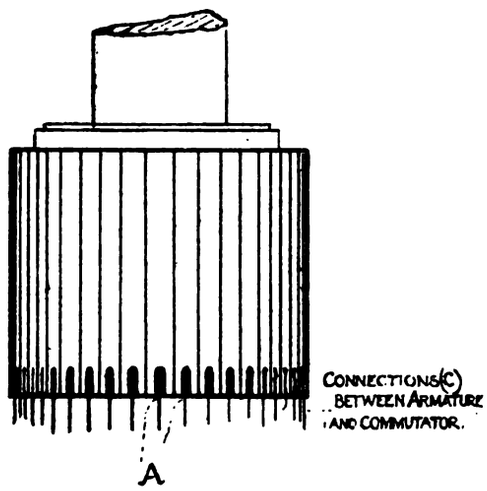

FIG. 2.

connections are shown of a small bipolar slot-wound armature, A being the armature coils and C the connections between the armature and the commutator. Several turns of steel binding wire are placed over the connections, C, thereby holding them firmly down on the insulated support, *x*. This arrangement is being used on armatures up to about 10 h.p. capacity; in many cases, where high voltages are used, the size of the wire in the connections, C, is less than No. 18 S.W.G., but no trouble is found with the wires breaking off. It may be mentioned that the wire used in the coils, A, is also used for the connections, C, in order to avoid any soldered joints, except, of course, where the connections are soldered to the commutator plates.

The standard practice on small commutators is to saw-cut small slots in the plates, as shown in Fig. 2. The connecting wires, C, are then placed in these slots and soldered up. In most cases these wires are tapped into the slots by means of a small hammer, and special care should be taken to prevent the wires being cracked at the point A (see Fig. 2). If accidentally a partial break does occur at this point, it is quite possible that the armature would work satisfactorily for a short time, but sooner or later it would break down due to excessive heating and natural weakness.

Without complete particulars of the design of the armatures to which "A. B. D." refers it is impossible to state definitely the alterations required to overcome the present difficulty, but the writer considers that by careful attention to the above-mentioned points satisfactory results will be obtained.—P.

Answer to No. 729 (*awarded* 5*s.*).—The breakage of end connections on an armature wound with a small size of wire is generally due to one or more of the following causes:

1. Neglect to firmly secure the top layer of the winding in place in the core slots. The slots should be closed by a hardwood strip, slightly larger than the actual slot, wedged firmly down to prevent outward movement of the wires due to centrifugal force as the armature rotates. These wedges will, of course, be surrounded with either presspahn or some other insulating lining. Two or more bands of binding wire should be tightly wound on mica strip over the wedges, and the ends properly soldered. A layer of strong twine should be placed over the *end connections* extending in width from the commutator lug inwards, at least a third of the distance from lug to core plates. Another similar binding should secure the straight wires where they leave the ends of the wedges. Space for ventilation is thus allowed between the two bindings and the connections prevented from bulging and breaking.

2. The soldering of such small wires is often done with too much heat. The copper becomes brittle, and will break very readily.

3. Any looseness of the commutator sleeve on the shaft, or movement endways, will, of course, strain the connections. The copper segments, if not properly tightened up, will move outwards, carrying the lugs with them and subjecting the connections to movement and possible breakage, for if badly put together, the copper segments will vary their position as soon as the machine gets warm, so straining the connections every time the load is put on. Some makers fit "expansion lugs" in the form of a semicircular bend in the commutator lug to permit a certain amount of expansion or vibration, but their use has been wholly abandoned in one shop well known to me without any apparent detriment to the machines.

4. An armature core is sometimes fixed to the shaft with too narrow a key. The result is that the plates cut themselves loose on the two outer edges, so allowing the whole core to work loose, and again break the end connections. A loose clamping nut may also be responsible for movement of the core.

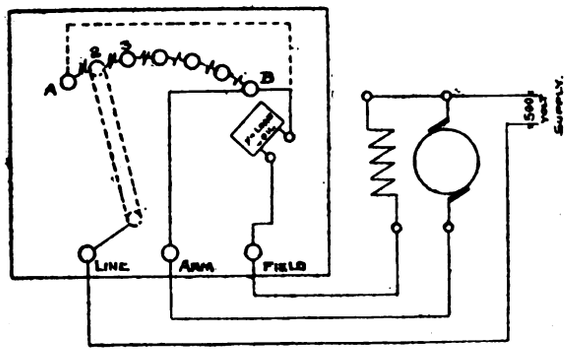
5. If the machine be well finished, but fixed on a bad foundation, the connections will soon suffer. I remember a case where several direct-geared motors were bolted down to some flags on an earth floor, the proprietors refusing to supply other foundations. The result was a constant succession of breakages of the end connections, which ceased entirely when the flags were replaced by proper foundations.—A. M. L.

Question No. 730.—I have a 5-h.p., 500-volt, shunt-wound motor whose behaviour is somewhat weird, for on starting up in the ordinary way with the usual type of shunt motor starter, the machine on "no load" starts on the second live contact of the starter, runs about 20 or 30 revolutions, and then, apparently remembering it is running the wrong way, stops, and reverses itself. All this happens before

Digitized by Google

the starter is put on the third contact, and except for this curious behaviour at starting, it behaves like any ordinary motor. There is no sparking at the brushes or abnormal current during this phenomenon. What causes it?

Answer to No. 730 (*awarded* 7*s.* 6*d.*).—Since the reversal of a shunt motor depends on the independent reversal of either the shunt or armature current, and as the armature current cannot be reversed in the case under consideration, it is clear that the curious behaviour of the motor at starting is due to a temporary reversal of the field current. This is very probably due to heavy armature reaction, which takes place before the field coils are properly energised. The actual value of the shunt current in the coils of the motor when the switch arm is moved on to contact A (in diagram) will depend on (1) the value of the



resistance interposed between the main or line terminal, L, and the no-load coil, which will be connected to the field coils as shown. If the no-load coil be connected to the end of the starter resistance marked B, it is clear that this resistance is inserted between the supply and the shunt coils at starting. Hence the exciting current will be reduced and the field intensity proportionately. (2) The shunt coils of a 500-volt motor possess considerable self-induction, which prevents the field current immediately reaching its full value when the circuit is closed.

Both these conditions are very probably fulfilled in the present case, resulting in a weak field excitation with the first movement of the switch arm. At the same moment current flows through the armature, the value depending on the resistance of the armature and the starting resistance. The latter will be calculated to *prevent* the passage of a dangerously heavy current on the first two or three contact positions of the switch arm, so that no sudden rush takes place during the starting period. The passage of this current causes a drop in volts across the field coils, and a further decrease of the exciting current. The resultant torque between the armature and shunt fields is insufficient to move the armature. When the switch is moved on to contact 2 the value of the armature current rises; the shunt current also increases, but in much less proportion. The armature field now reverses the weak magnetisation of the poles, and sufficient torque exists between the two fields to produce the rotation described. As soon, however, as the armature begins to run, a back E.M.F. is developed, resulting in (1) immediate decrease in value of the armature current, (2) consequent increase in the volts across the field coils. The shunt current becomes stronger, and reverses the polarity induced by the armature current. The armature stops, but the exciting current (which cannot change in value quickly, due to self-induction) suffices to maintain the polarity of the field—particularly as *drop* in the exciting current will mean a very brief extra current in the right direction to maintain the field—and the instant the armature starts in the right direction the field strengthens with the rising E.M.F. and the machine runs up to speed. If such a shunt connection exists it should be altered, as shown, to stud A, when the full voltage available will be applied to the field coils at starting. Should a considerable increase in speed be the result of so weakening the field at full load, connection may be tried at some point of the resistance intermediate between A and B.—A. M. L.

Answer to No. 730 (*awarded* 7*s.* 6*d.*).—It is quite evident from the particulars given that the motor runs in the wrong direction at starting, due to some defect in the rheostat and not in the machine itself, as the fact that on about the third stop it runs all right proves that there can be no defect in the motor. The reason for the machine running in the wrong direction is that the shunt field for some reason does not attain appreciable strength sufficiently quickly, thereby allowing the armature to induce a field of ito own, due to the current passing through it. This induced field would cause the motor to run backwards if the brushes had a backward lead, which, of course, is usual on motors that are not required to be reversible. Supposing the brushes happened by chance to have a forward lead, the direction of rotation would be the same throughout, though the motor would spark when the load came on at full speed.

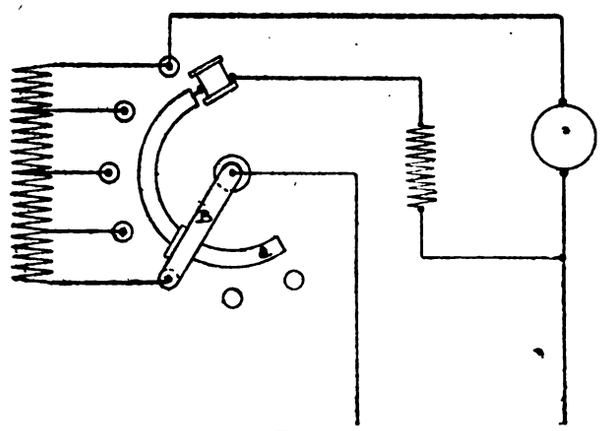


Fig. 1.

It would be easier to say what is amiss with the starter if more particulars as to the type in use had been given. It is, however, probable that it is of one of the two types shown in Figs. 1 and 2. Supposing that it were of the type shown in Fig. 1, then it is likely that the semi-circular contact *a* is not long enough (and, therefore, does not meet the spring contact on arm B soon enough), or else it may be worn down at that end, due to soft metal. The spring contact on arm B would seem to be all right, as it apparently meets *a* when the third contact stud is reached, as the motor then runs all right. On the whole, it seems probable that the starter is of the type shown in Fig. 2, which shows a form supplied by an American firm, and which is connected up incorrectly. Fig. 3 shows the correct connections. A large number of rheostats were made and sold wrongly connected. The defect has, however, been rectified in their later ones.

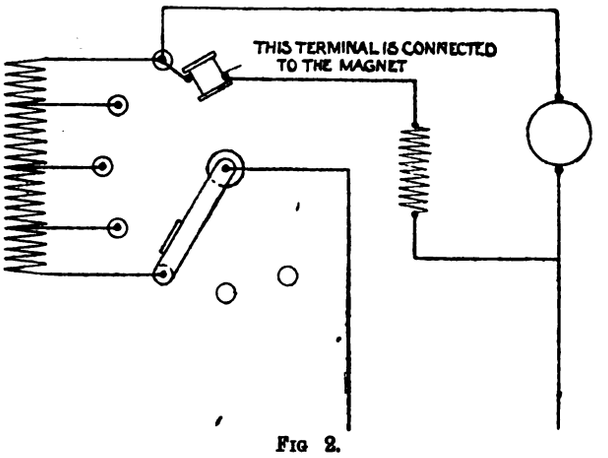

Fig 2.

Referring to Fig. 2, it will be seen that the shunt lead is taken off the last stop, which means that when the arm is on the first contact the whole of the resistance is in series with the shunt field as well as the armature. The large current flowing through wire brings the voltage down to, say, about 40 volts, which across a 500-volt spool winding will give a very small amount of field. This effect will, however, decrease by the time the third or fourth contact has been reached, due to drop in armature current, which thereby increases the volts across the field considerably. On the other hand, referring to Fig. 3, it will be seen that the full field is put in immediately the first live contact is

Digitized by Google

reached, and when the arm is on the last stop cutting out all the resistance from the armature circuit, it would be all in series with the field only for the fact that it is automatically cut out by the no-load release coil, the magnet of which is made to form part of the circuit. Even supposing it were not cut out, then it would form a negligible percentage of the whole field resistance; as there is such a small current flowing through it the voltage drop is very slight. It will be seen that this is the case when the arm is on the last contact but one.

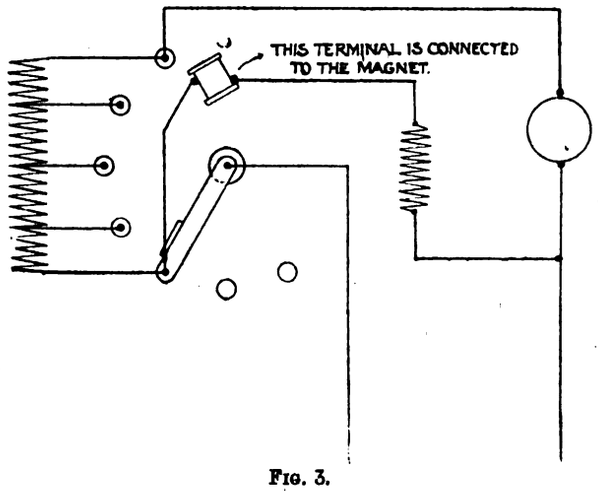

FIG. 3.

The reason that the machine does not spark is no doubt due to the large resistance in series with the armature when on the first two stops. I have seen a motor started with the brushes about on the neutral point, or perhaps slightly forward of it and with no field on. It commenced to rotate in the right direction at about the third or fourth contact, and there was no appreciable sparking till the fifth or sixth was reached, when it was shut down, the mistake being discovered.—R.

Answer to No. 730 (*awarded* 7*s.* 6*d.*).—As a motor ought not to behave in this erratic if intelligent manner, it is necessary to assume that there is some mistake in the connections. The simplest assumption that will explain the observed phenomena is that the shunt is connected across the brushes as shown in Fig. 1. The dotted line shows how it ought to be connected. With the shunt so connected, the exciting voltage before the motor starts is only that due to the ohmic drop in the brushes and armature. We must make one other assumption (a very likely one)—namely, that the brushes are set with a backward lead—that is to say, in the best position for running on load.

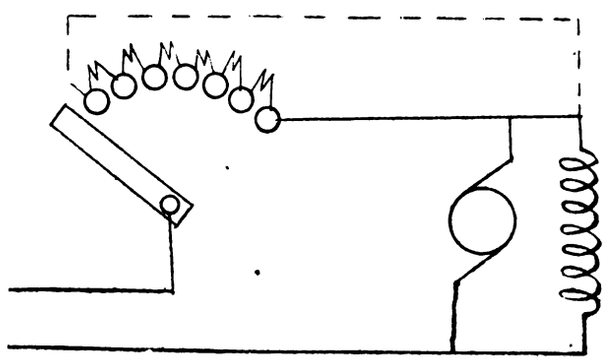

FIG. 1.

With this backward lead the armature ampere-turns tend to demagnetise the field, or, in the absence of any other field excitation, to cause a negative field. We thus see that there are two magnetising forces: first, the shunt, giving a positive magnetisation; and, second, the armature, giving a negative one. Now, the main circuit consists of a large practically non-inductive starting resistance and a small slightly inductive armature resistance, and may be considered as forming a non-inductive whole. On switching on, the full current allowed by the starting resistance at once passes. The shunt circuit, however, consists of a very large number of turns enclosing a large number of lines of force, and is consequently very inductive indeed. The shunt current, therefore, takes an appreciable time to rise to its maximum value.

What actually happens then is this: When the current is switched on, while the shunt current is still almost zero, the armature runs backwards because of the backward lead to the brushes. Meanwhile the shunt current is steadily growing, and its growth is slightly accelerated by the increase of voltage across the brushes due to the back E.M.F. of the armature. In a few seconds the shunt current overbalances the armature field, and the motor stops and then reverses. It is quite a chance that "H. G.'s" motor performs in this way, for if the brush lead or the self-induction of the shunt were a little less, or the friction a little greater, the motor would not run backwards, while these might be so proportioned that the motor would not start at all or would only run backwards. But we can easily show that the above is a possible explanation by considering an actual motor. A certain 5-h.p., 500-volt, four-pole shunt motor has the following values: full-load current, 9 amperes; resistance armature and brushes, 2·5 ohms; total armature turns, 1,200; total armature flux, 1·56 million lines; total flux, 1·8 million lines; total turns on shunt, 36,000; resistance of field, 1,600 ohms cold. If the starter passes full-load current on the second contact, volts across brushes = 22·5 volts, then total ampere-turns in shunt = $\frac{22{\cdot}5}{1{,}600} \times 36{,}000 = 505$.

To give the desired effect, the back ampere-turns of the armature must be less than this—say 320. This requires a backward lead of about 5deg.

Again, with ·26 ampere in the shunt each turn cuts ·9 million lines.

$$\text{S.I.} = \frac{\text{megalines per one ampere} \times \text{turns}}{100}$$

$$= \frac{\cdot 9}{100} \times \frac{1}{\cdot 26} \times 36{,}000 = 1{,}250 \text{ henrys.}$$

$$\text{Time constant} = \frac{L}{R} = \frac{1{,}250}{1{,}600} = \cdot 78 \text{ second.}$$

The shunt current, therefore, rises along an exponential curve whose time constant is ·78 second. Fig. 2 shows

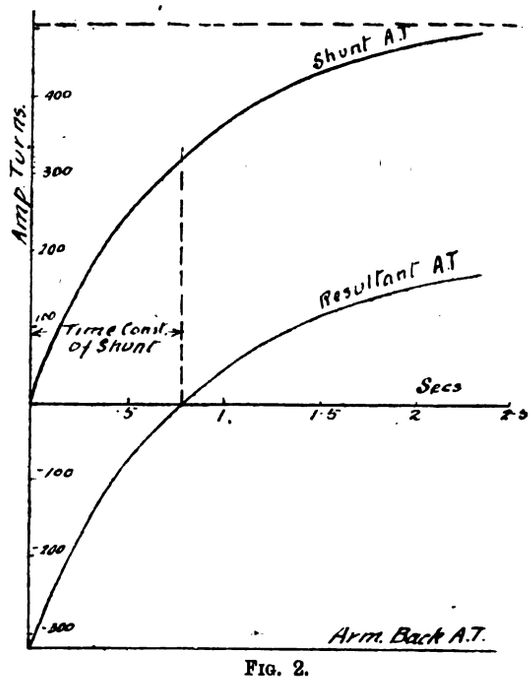

FIG. 2.

the result graphically. The field is negative for ·78 second, by which time it has fallen to zero, and after that it is positive.—W.

Supplement to "The Electrical Engineer,"
NOVEMBER 18, 1904.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

QUESTIONS.

739. A 50-h.p. gas-engine and a 40-h.p. motor, shunt-wound, are connected by belts and clutches to the main shaft of a factory, so that in the event of the gas-engine breaking down the motor may take the load running on town current at 460 volts. It is desired to instal two electric cranes requiring 12 h.p. each, and to feed them by driving the motor as a dynamo when gas-engine is running, and direct from town mains if gas-engine is stopped and motor has to drive the factory. What voltage would we likely get, and what is the best arrangement of switchgear, etc., for changing over?—D. R.

740. I have been much interested in the statistics given by Mr. J. Hall (*E. E.*, Nov. 4) concerning the "Raworth system of regenerative control for electric traction." Could anyone give me diagram of the application, with detail of controllers, etc. If it gives all that it is claimed to do, why is it not generally adopted in preference to the S.P. control? Are not the reduced expenses counterbalanced by failings (due to shunt motor) of greater consideration? A comparison of the two systems is invited.—W. B.

ANSWERS.

Question No. 730.—I have a 5-h.p., 500-volt, shunt-wound motor whose behaviour is somewhat weird, for on starting up in the ordinary way with the usual type of shunt motor starter, the machine on "no load" starts on the second live contact of the starter, runs about 20 or 30 revolutions, and then, apparently remembering it is running the wrong way, stops, and reverses itself. All this happens before the starter is put on the third contact, and except for this curious behaviour at starting, it behaves like any ordinary motor. There is no sparking at the brushes or abnormal current during this phenomenon. What causes it?

Answer to No. 730 (*awarded* 5*s.*).—The cause of this phenomenon is that the shunt current has not time to build up before the second live contact is reached, and the motor field, owing to the position of the brushes, becomes excited by the current in the armature. It is well known that when the brush axis is placed (as in Fig. 1) at right angles to the magnetic axis the field is distorted, but as a

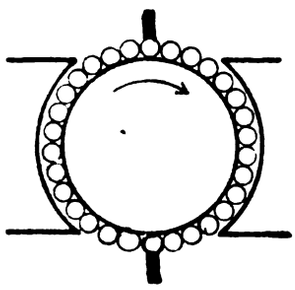

FIG. 1.

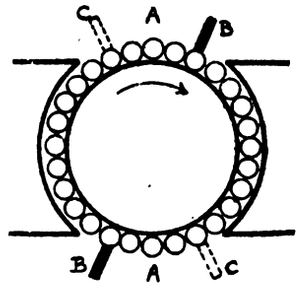

FIG. 2.

whole is not appreciably altered in value. When, however, the brush axis is moved away from the neutral position (as in Fig. 2), a real magnetising or demagnetising results, because the conductors between A and B, instead of opposing those between A and C as before, help them, and even with no current in the magnet coils the machine will now magnetise itself. This principle has been used to a considerable extent in toy motors. The idea of shifting the position of the brushes is to facilitate sparkless commutation, and the direction of the rotation of the brush axis for this purpose is in the case of generators the same as that of the armature, and in the case of motors in the opposite direction, so that taking the armature in Fig. 2 as revolving as indicated by the arrow, when acting as a generator the brush will be at B, and when being used as a motor at C. Now, when a machine acts as a motor the torque is in an opposite direction to that when it is used as a generator, and taking it that the field is magnetised in the same direction in both cases, it follows that the current (the other factor in producing the torque) must flow in opposite directions through the armature in these two cases. Suppose when acting as a motor the current flows *in* at C, then when acting as a generator it will flow *out* at A, and it is clearly seen that in the conductors between C and A the current flows always in the same direction, whether machine is acting as motor or generator. When the brush is shifted forward in a generator the field is demagnetised, therefore the field is also demagnetised when the brushes are shifted backwards in a motor, and if the current is switched on to the armature before the field current is on the motor will be partly magnetised in the wrong direction, and will start turning in the wrong direction. When the field is switched on and grows to its full value, it will have completely overcome the back action of the armature, and the motor will be revolving in its proper direction. As the current is in any case kept down entirely by resistance at starting, excessive current will not flow in this case, and as to sparking, it must be a very poor motor, indeed, which sparks at all at starting, because the frequency of commutation is then so low. The remedy is, of course, to look at the starter and see if the field is really made on what appears to be the first live contact, and if it is, to keep the starter arm on that contact for a sufficiently long time to allow the field current to grow to its normal strength. The writer always considers it advisable to have a main switch installed in the starting equipment, and not to rely upon the starter to fulfil that function. The shunt connections are then made across the motor side of the switch, and the shunt current has then time to grow during the period which elapses between the shutting of the switch with the right hand and the consequent manipulation of the rheostat arm with that *same* hand.—P.

Question No. 731.—How would you measure the self-induction of an alternator's armature?

Best Answer to No. 731 (*awarded* 10*s.*).—The practical methods of determining the self-induction of the armature or stator of an alternator may be classified under two heads—viz.: (1) by applying current at a known frequency and taking simultaneous readings of voltage and current and voltage at terminals of machine, and (2) by taking saturation tests on the machine, from the results of which the inductance can be calculated. Before discussing these methods in detail, it will be advisable to investigate the matter of inductance of alternator windings. In calculations respecting direct-current machinery, it is the inductance of the turns undergoing commutation at the brushes which is of the chief interest. This can be estimated with fair exactness from experimental data available, firstly, because the range of sizes and shapes of slots and coils is not extremely great, and secondly, because the required value of inductance corresponds to the position of the coil in the open space between the pole-tips Numerous tests have shown that the inductance of the coils under these conditions is about the same when the armature is in position in the field frame, and when it is free in the air. Now, in alternators an entirely different state of affairs exist, as it is required to be able to estimate the inductance for *all* positions of the armature relatively to the rest of the magnetic circuit, and not for a small compact group of coils, but often for more or less distributed windings. The effect of the field-magnet system has a great influence on the values of the inductance measured when the field is in position and when it is removed. Thus the proximity of magnetic material so situated as to decrease the reluctance of magnetic circuit will have a tendency to increase the values of the inductance. With windings embedded in partly closed or tunnel slots (as is the practice with Continental builders) this difference is not so marked as with open slots. The arrangement of the magnetic circuit, whether solid or laminated, has also a great influence on the values obtained for the inductance. The approach of solid masses of magnetic material affords paths for induced secondary currents, and the inductance will not be increased to such an extent as for correspondingly situated laminated masses of magnetic material. As it is

Digitized by Google

generally the *average* value of inductance that is required, it will be seen from the above that, for the method coming under the first classification, readings should be taken with the armature in different positions relative to the field, the latter, of course, being in place. The extent to which the inductance varies for different relative positions of armature and field system is indicated in Fig. 1, in which the curve represents the values of inductance for different positions. The average inductance is, of course, obtained from the mean of the ordinates. A description of the above methods for the practical determination of inductance will now be given and values deduced from observed results in each case.

Method 1.—If the machine is a single-phaser, alternating current from a similar machine—*i.e.*, a machine giving the same frequency as the one under test—is applied to the terminals, and amperes input and volts drop across the terminals observed on suitable instruments. If E is the impressed E.M.F. required to pass a current, C, through the armature of the alternator, the ohmic resistance of which is R, then it is known that

$$C = \frac{E}{\sqrt{R^2 + (2\pi L n)^2}}.$$

In dealing with alternators, the ohmic resistance may generally be neglected in comparison with the reactance ($2\pi n$ L), and hence for any value of current up to about full load the C R drop is very small in comparison to the

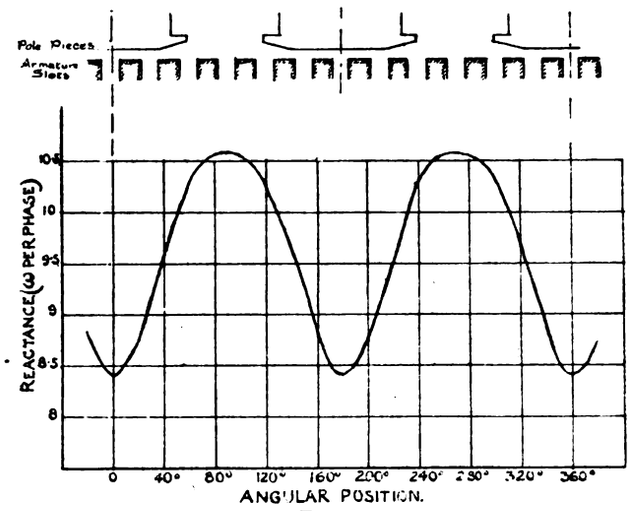

FIG. 1.

reactance voltage, and the reactance can, therefore, be obtained from $\frac{E}{C}$. With a three-phase machine the procedure is very much the same, but a knowledge of the connection of the windings is required in interpreting the results. In this case three-phase current is supplied, an ammeter being inserted in each line. If the windings are Y-connected (which is the general connection for high voltages) and the voltage measured across each pair of terminals, as in Fig. 2A, the expression for the volts per phase becomes $\frac{\text{volts across terminals}}{\sqrt{3}}$, the value of the ampere per phase being taken equal to the mean of the three ammeter readings. The reactance *per phase*, which is of chief interest, is then at once obtained as in the previous case. If, however, the volts are measured as in Fig. 2B—*i.e.*, between each terminal and the centre point of the star (or "Y-point")—the value of the volts per phase is obtained direct. With a Δ-connection for the winding, the amperes per phase are found by dividing the line amperes by $\sqrt{3}$, the volts per phase then being voltage across terminals. The reactance may also be determined by the application of single-phase current, the readings being taken with connections as in Figs. 2C and 2D; the former case giving readings for reactance per phase, while the latter gives the reactance of two phases in series, and hence reactance per phase will be one-half of that measured. Generally, the values obtained by this method of single-phase current lead to a slightly lower average value for the inductance than that obtained with three-phase current. In both these cases it is preferable to obtain readings with the armature and field in different relative positions.

The curve shown in Fig. 1 represents the inductance of the armature of a three-phase alternator of 850 kw. output, a few of the leading particulars being given in the following specification: rated output, 850 kw.; speed, 94 revolutions per minute; frequency, 25 ∼ per second; terminal voltage, 5,000 volts; connection of winding, Y; full-load current per phase, 98·5 amperes; armature slots per pole-piece, 6; slots per pole-piece per phase, 2; conductors per slot, 14. The machine is of the revolving-field type with 32 poles. The values for the reactance per phase, given in Fig. 1, were obtained from measurements made with three-phase current at 25 ∼, and the average value from the curve is 9·6 ohms per phase. Hence, since reactance = $2\pi n$ L (where n is the frequency and L the self-inducance in henrys), therefore

$$L = \frac{9{\cdot}6}{2 \times \pi \times 25} = {\cdot}061 \text{ henry.}$$

This is the average inductance of the armature per phase. But it is customary and more convenient when dealing with inductance calculations to express the inductance in terms of the number of lines per ampere-turns per inch length of

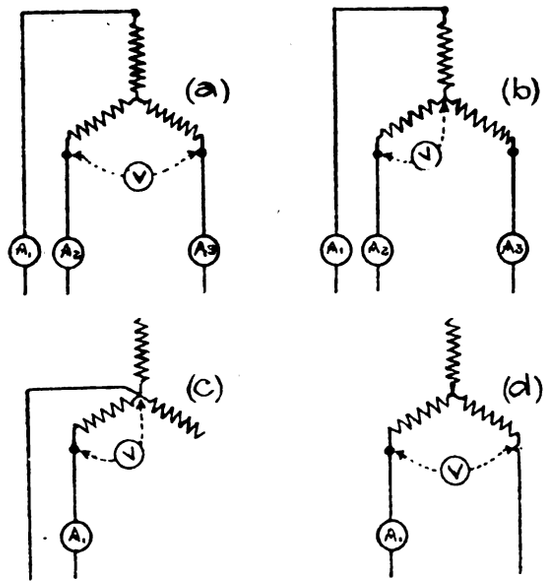

FIG. 2.

armature laminations. By this process all results are brought to a standard basis, and different designs can be easily compared. A coil is said to have an inductance of one henry when it is of such dimensions that a current of one ampere sets up a magnetic flux of such a magnitude that the product of the number of lines linked with the coil multiplied by the number of turns in the coil is equal to 100,000,000. If the coil has but one turn, then its inductance in henrys becomes 10^{-8} times the number of lines linked by the turn when one ampere is passing through it. Since one ampere passing round n turns sets up n times the flux that would be set up in passing round one turn, and as this flux is linked with each of the n turns, it follows that the product of the flux multiplied by the turns will be $(n)^2$ times as great as with one turn. In the machine under consideration there are 14 conductors per slot and two slots per pole per phase, and hence 28 turns in series per group of coils. The total groups of coils per phase will be 16. Hence the inductance per group of coils $= \frac{{\cdot}061}{16} = {\cdot}0038$ henry. The gross length of armature laminations is 14·5in., and therefore linkage of lines per inch length of armature laminations $= \frac{380{,}000}{14{\cdot}5} = 26{,}300$ lines. Hence lines per ampere-turn per inch length of armature laminations $= \frac{26{,}300}{(28)^2} = 33{\cdot}5$ lines for the average of all positions.

Method 2.—In applying this method the inductance is calculated from the observed saturation curves taken at no

Digitized by Google

load and at full load with unity power factor. The no-load and full-load saturation curves for the 850-kw. alternator referred to above are given in Fig. 3, the scale of volts being reduced to correspond to the voltage *per phase*. We shall now proceed to analyse these curves, and deduce from them the reactance per phase. Independent calculations for the reactance will be made, taking three points on the no-load saturation curve—viz, 1,500, 2,000, and 2,880 volts per phase. The resistance per phase of the armature is ·315 ohm, and the C R drop at full load is $·315 \times 98·5 = 31$ volts. Therefore, the corresponding voltages on the full-load saturation curve are 1,469, 1,969, and 2,849 volts. From Fig. 3 we obtain the following data:

Voltage per phase	1,500	2,000	2,880
Excitation at no load (ampere-turns per spool)	3,100	4,300	7,650
Excitation at full load (98·5 amperes) and unity power factor (ampere-turns)	4,970	5,830	8,800

The difference between these two values of field excitation equals the ampere-turns required for overcoming armature demagnetisation.

Therefore ampere-turns required for overcoming armature demagnetisation	1,870	1,530	1,150

Assuming a sine wave distribution of the flux, the total armature strength by calculation is at full load equal to $14 \times 98·5 \times \sqrt{2} \times 2 = 3,900$ ampere-turns. The observed value is 3,700 ampere-turns, which will be used in the calculations below. It is convenient, and sufficiently accurate, to take the demagnetising effect of the armature as increasing proportionally to the sine of the angle of lag

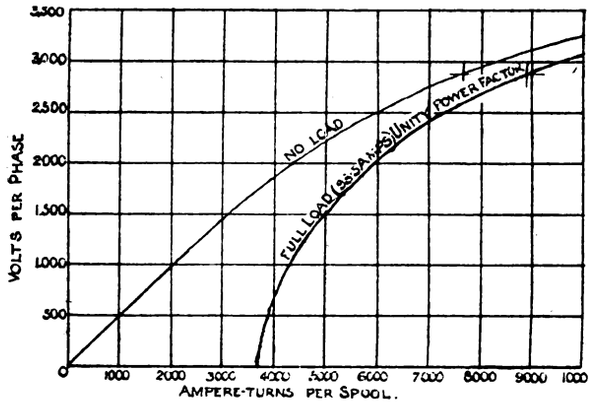

FIG. 3.

between the mid pole-face position and the position of the conductors when carrying maximum current. Hence, if θ be the angle of displacement of maximum current behind the mid pole-face position, we have for the three cases above:

3,700 sin θ equals	1,870	1,530	1,150
$\therefore$ sin θ equals	0·505	0·414	0·311
And tan θ equals	0·59	0·456	0·328

Now, tan θ is the ratio of the reactance voltage per phase to the impressed voltage per phase, and hence in the case under consideration we have

Tan θ equals	$\frac{R\,V}{1,500}$	$\frac{R\,V}{2,900}$	$\frac{R\,V}{2,880}$
Therefore reactance voltage at 98.5 amperes equals	885	912	945

The mean of these three values is 914, which value will be used for the reactance voltage per phase at full load.

Hence reactance per phase $= \frac{914}{98·5} = 9·3$ ohms, a value not materially different from that obtained by Method 1.

The value of the total armature strength (3,700 ampere-turns) is obtained by observing the field excitation required to send full-load current through the armature when short-circuited and run at normal speed. Under these conditions the maximum current is reached when the armature slot is 90deg. behind the mid pole-face position, and the full armature strength is in this case exerted in opposition to the field magnetomotive force. The field excitation, therefore, has to be in excess of this amount by the small percentage to overcome the small C R drop in the conductors. The curve obtained by plotting field excitation as abscissæ and short-circuit armature current as ordinates is a straight line passing through zero, and is designated the "short-circuit" characteristic.—MONOPHASE.

Answer to No. 731 (*awarded* 7*s.* 6*d.*).—An alternator armature cannot be said to have a definite single coefficient of self-induction, for the number of magnetic lines self-induced through the armature coils per ampere varies (1) with the relative position of the armature coils and the magnet poles (the inductive effect being, of course a maximum when the coil centres are directly opposite the poles); (2) with the power factor of the armature load (for with unity power factor the maximum value of the armature current occurs when the centres of the armature coils

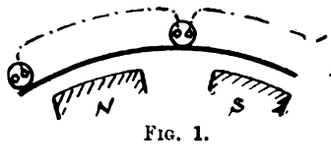

FIG. 1.

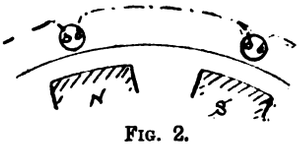

FIG. 2.

are midway between two poles, Fig. 2, and in their least effective position, whilst with a 90deg. phase displacement this maximum current value occurs when the coils are in their most effective position—*i.e.*, directly opposite the poles, Fig. 1); (3) with the actual value of the current (slightly more lines being induced per ampere of a low current than of a high one owing to the effect of iron saturation); (4) with the state of saturation of the field magnets—*e.g.*, whether they are excited or unexcited. On this account it is only possible to obtain a value which may for convenience be called the "coefficient of self-induction," but which really only represents the inductance of the armature under one particular set of conditions.

One of the simplest ways of doing this is to make a short-circuit test on the alternator. The armature is short-circuited through an ammeter, and the field is only just sufficiently excited to cause the normal full-load current to circulate in the armature when it is driven at about normal speed. The exciting current to produce this state is noted, and a reading is next taken of the terminal volts on open circuit with this same excitation. This open-circuit voltage is equal to the total drop in the armature during the short-circuit reading. This drop is made up of the volts lost in the resistance of the armature winding, the inductive drop due to magnetic lines set up around the armature wires, and the drop due to reduction in the main flux looped with the armature coils, brought about by the armature back ampere-turns. The last two quantities need not strictly be distinguished from one another, for a reduction in the main flux or the setting up of a new flux in the opposite direction, both due to the armature current, give practically identical results. The C R or ohmic drop is easily obtained by measuring the resistance of the armature winding, and since the C R drop is in phase with the armature current, whilst the inductive drop is in quadrature with the current,

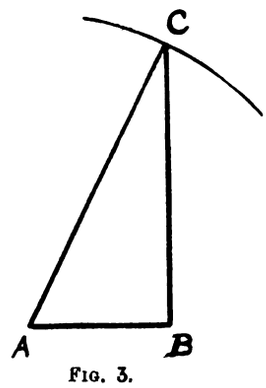

FIG. 3.

the resultant drop on the short-circuit test (equal to the open-circuit volts in this case) will form the hypotenuse of a right-angle triangle, of which the C R and the inductive drops respectively are the sides. Draw a line, A B (Fig. 3), to represent the C R drop to any scale. With A as centre and a radius equal, on the same scale, to the open-circuit volts measured as above, draw an arc of a circle. From B draw B C at right angles to A B and to meet the arc. Then B C represents the total inductive drop, and the correspond-

Digitized by Google

ing value of the coefficient of self-induction, L, in henrys, may be obtained from the fact that inductive drop = B C $= \pi \frown\!\!\smile$ L C volts, assuming a sine wave of E.M.F., where $\frown\!\!\smile$ = the periodicity at which the test was made, C = the armature current on the short-circuit test. The value of L so obtained is the effective self-induction of the armature at normal current, with a phase displacement of the current of nearly 90deg. (the power factor on a short-circuit test being nearly zero with most types of alternator owing to the great preponderance of the inductive drop over the resistance drop), and with a very weak field excitation. The result can therefore hardly be considered as the coefficient of self-induction under normal conditions, but it is sufficiently close to this to permit of fairly reliable results as regards the drop of the alternator being deduced from it.

Another method of obtaining the effective value of L consists in passing an alternating current about equal to the full-load current round the alternator armature whilst it is at rest, but with the field magnets excited to the normal extent. The volts required to pass the current round the armature winding are again equal to the resultant of the C R drop and the inductive drop, and the value of the latter and of L can be obtained by means of a right-angle triangle, exactly as in Fig. 3. The test must be repeated with the armature coils in two or three different positions, relatively to the pole-faces, varying from right opposite the poles to midway between the poles. The average of these three or four results for L will be the effective value under normal current and excitation conditions, but with only an approximation to the real relative positions of armature coils and magnet poles, which correspond to the various instantaneous current values when the alternator is running under normal conditions. The effect of this discrepancy on the effective value of L under working conditions is, however, only very slight.—Q.

Answer to No. 731 (*awarded* 5*s*.).—Before answering this question, it would be as well to examine what is here meant by the term "self-induction." Obviously, the self-induction of the armature will depend on its position relative to the field magnets; its maximum value will correspond to the position of zero E.M.F., and its minimum value to the position of maximum E.M.F., so that it is seen the self-induction of the armature will fluctuate with a frequency double that of the induced E.M.F. For all practical purposes we may consider the armature as possessed of a constant self-induction or inductance (we will use the latter term), and this we will call its "equivalent inductance." This, then, is what is required to be determined, and it can be done in the following manner. First run the alternator at normal speed, and take a set of readings connecting exciting current and E M.F. These can be plotted in the form of a curve, which may be called the "open-circuit characteristic." Secondly, short-circuit the alternator through an ammeter (this should be of negligible inductance: a hot-wire instrument would do very well), and then take another set of readings connecting the short-circuit armature current with the exciting current. From these readings another curve is plotted, which may be called the "short-circuit characteristic." Now suppose that, corresponding to any value of the exciting current, the E.M.F. obtained from the first curve is represented by E, and that the short-circuit current corresponding to the same exciting current, obtained from the second curve, is represented by C; if the resistance of the armature = R, which can easily be ascertained by measuring the drop across the armature with a known continuous current passing, then we have

$$C = \frac{E}{\sqrt{R^2 + L^2 p^2}}$$

where $p = 2 \pi \times$ frequency.

$$\therefore L p = \frac{\sqrt{E^2 - C^2 R^2}}{C}$$

$$L = \frac{\sqrt{E^2 - C^2 R^2}}{C p}$$

where L = equivalent inductance of armature. As L p is appreciably large compared with R, the current, C, will lag by nearly 90deg. behind E, so that the value obtained for L will be greater than what it would be if C was in phase with E, for obviously in the first case the current reaches its maximum for a position of the armature corresponding to its maximum inductance. In the above it has been assumed that the current and E.M.F. waves have been true sine waves, which, of course, is never absolutely attained in practice.

From the above it will be seen that the equivalent inductance of the armature will vary with the displacement of the main current with respect to the E.M.F.—*i.e.*, the power factor of the load—so that it is a very uncertain quantity. This variation in the equivalent inductance could be shown by inserting a non-inductive resistance in series with the armature, and then again obtaining the short-circuit characteristic. This will have the effect of increasing R with respect to L p, and thus decreasing the lag of the current, C, behind E, and if the value of the non-inductive resistance is known, the equivalent inductance, L, can be again determined. The fluctuation of the inductance of the armature with varying positions could be shown by measuring the inductance corresponding to different positions taken over half a period. To do this for any given position, pass a known alternating current, C, through the armature and measure the drop, E, on a voltmeter. Then, as before,

$$L = \frac{\sqrt{E^2 - C^2 R^2}}{C p}.$$

Repeated for different positions, a curve showing the fluctuation could be plotted.—A. P. YOUNG.

Answer to No. 731 (*awarded* 5*s*.).—The best, and certainly the simplest, method of measuring the self-induction of a circuit is to use the well-known formula

$$\tan \theta = \frac{\text{reactance}}{\text{resistance}},$$

$$\text{reactance} = 2 \pi n L,$$

where n = frequency and L = self-induction in henrys. Simplying the above equation, we get

$$L = \frac{\tan \theta \times \text{resistance}}{2 \pi \text{ frequency}}.$$

Tan θ can be found from tables, as $\tan \theta = \frac{\sin \theta}{\cos \theta}$. There are two methods of arriving at the power factor (cos θ) of a circuit which are commonly used in shop practice—viz.:

1. Apply an alternating current to the armature winding, then by means of a voltmeter, ammeter, and wattmeter the power factor (cos θ) can be readily obtained.

$$\cos \theta = \frac{\text{watts}}{\text{amperes} \times \text{volts}}.$$

2. Apply an alternate current of known voltage, E, and measure the watts with wattmeter, then

$$\cos \theta = \frac{\text{watts with alternating current}}{\text{watts with direct current}}.$$

The watts with direct current of voltage $E = C^2 R$, current being found by Ohm's law.

Example.

Armature resistance = 2 ohms.
Frequency = 100 cycles per second.
Voltage applied = 100.
Wattmeter reading, 40.
$C^2 R = 50^2 \times 2 = 5{,}000$.

$$\text{Cos } \theta = \frac{40}{5{,}000} = \cdot 008.$$

$$\text{Tan } \theta = \frac{\cdot 999}{\cdot 008} = 125 \text{ (approximate)}.$$

$$L = \frac{\tan \theta \times \text{resistance}}{2 \pi \times \text{frequency}} = \frac{125 \times 2}{2 \pi \times 100} = \cdot 4 \text{ henry}.$$

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

ANSWERS.

Question No. 732.—What is the best method of predetermining the voltage drop due to magnetic leakage in a transformer at, say, full load and any given power factor?

Best Answer to No. 732 (*awarded* 10*s.*).—The drop in the terminal volts between no load and full load on a transformer is due to the combined effect of the C R volts lost in the resistance of the primary and secondary windings, and the back voltage due to magnetic leakage between the primary and the secondary. The C R voltage is in phase with the current, whilst the leakage drop is in quadrature with the current, so that in order to determine the actual

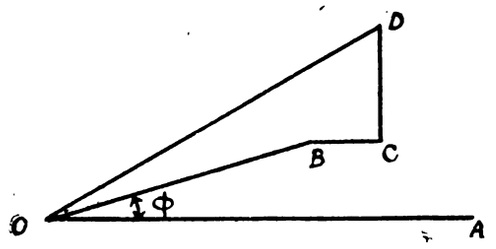

Fig 1.

drop these two quantities must be combined vectorially with the terminal voltage, as shown in Fig. 1. O A represents the phase of the secondary current; O B, the value of the full-load secondary terminal voltage required, drawn at an angle ϕ to O A equal to the angle of phase displacement between the secondary current and voltage for the particular load for which the drop is to be determined—*i.e.*, cos ϕ is the power factor of the load. When the load consists of condensers, so that the current is a *leading* one, the angle ϕ will be set out below the line O A instead of above it. From B draw B C parallel to O A and equal to the C R drop in primary and secondary windings reduced to the secondary side—*i e*, B C = secondary resistance × secondary current + (primary resistance × primary current $\times \frac{\text{secondary turns}}{\text{primary turns}}$). From C draw C D at right angles to O A and equal to the drop due to magnetic leakage calculated, as explained below. Then O D will be the no-load terminal voltage required in order to obtain the full-load voltage O B, and O D − O B will equal the voltage drop. Stated as a percentage of the no-load voltage, the drop $= \frac{O D - O B}{O D} \times 100$.

The approximate value of the leakage drop may be arrived at by the following considerations (see Kapp, *Elektrotechnische Zeitschrift*, April 14, 1898, and Kapp's "Transformers"): When a transformer, such as is shown diagrammatically in Fig. 2, is on open secondary circuit, a definite alternating flux passes through both primary and secondary windings, and its maximum instantaneous value is given by

$$\text{Flux} = \frac{\text{primary volts} \times 10^8}{4{\cdot}44 \times \text{total primary turns in series} \times \sim}.$$

This total flux, as far as the primary winding is concerned, is practically constant at all loads (at full load the internal primary volts fall from ½ to 1 per cent. owing to loss in the primary resistance, and this causes a corresponding drop in the flux, but this small difference may be neglected). As regards the secondary, however, the flux actually looped with its turns changes with the load owing to the fact that as the load on the transformer and the total ampere-turns in the primary and secondary windings increase, more and more of the primary flux, instead of being practically all confined to the iron circuit of the transformer, leaks back through the air (somewhat as shown by the dotted arrows in Fig. 2), and so, though the total flux linked with the primary turns remains unchanged, some of it returns through the space occupied by the primary winding, the insulation between primary and secondary and the secondary winding, and so is entirely or partially ineffective as far as the secondary winding is concerned. The amount of this leakage flux depends on (1) the ampere-turns of primary or secondary (which are practically equal at anything approaching full load) on each limb; (2) the average length of the leakage path in air, as shown by the dotted arrows, *d*, in Fig. 2; (3) the effective area of the leakage paths in air—*i.e.*, some function of the width of a primary coil + a secondary coil + the insulation between them multiplied by the mean periphery of the coils—*i.e.*, the mean length of one turn of wire in the primary and the secondary.

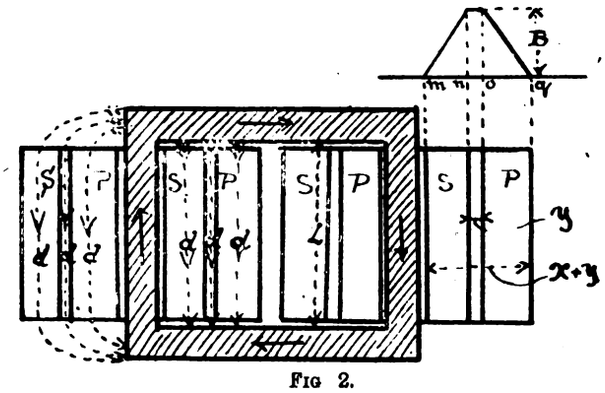

Fig 2.

The density of the leakage flux varies from zero close to the iron core within both the primary and secondary windings (as there are no effective ampere-turns there) to a maximum in the space occupied by the insulation between primary and secondary (where the full ampere-turns of the primary, or secondary, coil are effective in producing leakage) and then down again to zero at the extreme outside of the secondary coil (where the primary ampere-turns are practically neutralised by the equal and opposite secondary ampere-turns). The variations of the flux density from point to point of the winding are, in fact, somewhat as shown in the small figure in the right-hand corner of Fig. 2, assuming that the length of air-gap in the leakage path is constant for all points of the winding—an allowable assumption, considering that the depth of winding space is always fairly small as compared with the length of the winding space.

Now, the leakage flux which passes through the insulation between the primary and the secondary (*n* to *o*, Fig. 2) is fully effective on all the primary turns and wholly ineffective on the secondary turns. The flux in the space *m* to *n* varies in its effectiveness on the primary winding, the portions near the iron core being effective on fewer primary turns than those nearer the outside of the primary. None of this flux (*m* to *n*) is effective on the secondary winding. The flux in the space *o* to *q* is all fully effective on all the primary turns, but varies in its effectiveness on the secondary turns, the part nearer the primary winding being effective on fewer secondary turns than the part nearer the outside

Digitized by Google

of the secondary coil. In order to decide the effective leakage flux actually producing a drop, the "equivalent amount" of leakage which is wholly effective on all the primary turns, and wholly ineffective on the secondary turns—*i.e*, the effective difference between the primary flux and the secondary flux at full load—must be arrived at. This can be easily found by a step-by-step process carried out on the small curve (*m* to *q*, in Fig. 2) at half a dozen or more equally spaced points, or by means of a simple integration.

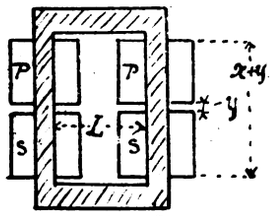

FIG. 3.

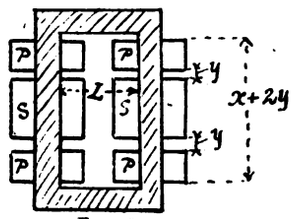

FIG. 4.

Calling the maximum flux density—*i.e.*, the flux density in the part *n* to *o*—B C.G.S. lines per square inch, it will be found that this "equivalent flux" density for the space *m* to *n* is $\frac{1}{3}$ B; from *n* to *o*, of course, the equivalent flux density will be equal to the actual flux density = B, whilst for the space from *o* to *q*, again, the equivalent density is $\frac{1}{3}$ B. Therefore, if *l* = mean length of a turn of primary or secondary winding—*i e.*, the periphery measured in the insulation between the primary and secondary in Fig. 2—in inches; *y* = thickness of insulation between the primary and the secondary coil (measured from copper to copper) in inches (see Figs. 2, 3, 4, and 5); *x* = width of winding space per limb—*i.e.*, combined depth of the primary and secondary windings per limb—in inches (see Figs. 2, 3, 5, and 5), we may say total equivalent leakage flux wholly effective on all the primary turns alone = B × *l* × $(y + \frac{1}{3}x)$ C.G.S. lines. This result remains the same whether the primary or the secondary is wound next the iron core.

The value of B can be obtained from the ampere-turns existing at the particular load in question and the ordinary air-gap flux formula

$$\text{Density C.G.S. lines per square inch in air} = \frac{\text{ampere-turns}}{\cdot 313 \times \text{length of air-gap}}.$$

Now, if A T = primary ampere-turns (or secondary ampere-turns) *per limb* = primary current × primary turns per limb at the load in question, the maximum instantaneous value of the ampere-turns will be 1·41 × A T, assuming a sine wave of current, and the maximum instantaneous value of the flux density in the insulation between the primary and the secondary will =

$$B = \frac{1{\cdot}41 \text{ A T}}{\cdot 313 \times \text{average length of leakage line such as } d\,d \text{ (Fig. 2)}}$$

$$= \frac{4{\cdot}5 \text{ A T}}{\text{average length of leakage line}}$$

∴ Total effective leakage flux

$$= \frac{4{\cdot}5 \times \text{A T}}{\text{average length of leakage line}} \times l \times (y + \tfrac{1}{3}x).$$

The drop in volts due to this leakage is

$$\text{No-load secondary volts} \times \frac{\text{effective leakage flux}}{\text{total no-load flux}},$$

and this is the number of volts to which C D in Fig. 1 is to be made equal.

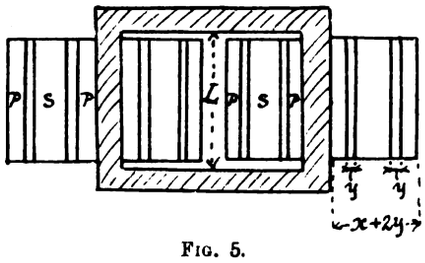

FIG. 5.

The average length of leakage path and the maximum number of ampere-turns effective in producing B vary with the arrangement of the coils. If the windings on each limb are split up into several primary coils and several secondary coils alternately interleaved, it is clear that (1) the maximum effective ampere-turns for producing leakage at any one point will fall, and (2) the area of the leakage path (corresponding to the length *m* to *q*) will also fall, so that a rapid falling-off in the leakage occurs—in fact, the drop in a transformer due to leakage falls almost as the square of the number of coils per limb.

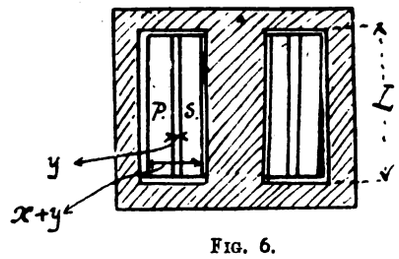

FIG. 6.

Applying the same method as described above to various other arrangements of coils, such as those shown in Figs. 3, 4, 5, and 6, and employing for simplicity the distance L inches from iron to iron inside the transformer, measured parallel to the insulation between primary and secondary (see Figs. 2 to 6) as the "average length of leakage line," it can be shown that the effective leakage flux is given with fair accuracy by the general formula:

Leakage flux effective on all primary turns and on no secondary turns in C.G.S. lines

$$= \frac{\text{A T} \times l}{\text{L} \times \text{K}^2} (3 \text{ K } y + x) \text{ C},$$

where A T, *l*, *y*, *x*, and L have the above-described values, and K = number of separate primary (*or* secondary) coils *per limb*. (When there are more coils in one winding than in the other, use the larger number for K—*e g.*, if there were two primary coils and one secondary coil per limb interleaved (as in Fig. 4 or Fig. 5). K would equal 2.) C = a constant which experiment has shown to equal about $2\frac{1}{2}$ to 3 for "core" type transformers (Figs. 2, 3, 4, and 5), and about $3\frac{1}{2}$ to 4 for "shell" type transformers (Fig. 6) with all the winding on one limb.—Q.

Answer to No. 732 (*awarded* 7*s.* 6*d.*).—By a transformer having magnetic leakage, we mean that a certain number of lines of force which thread the primary winding do not thread the secondary winding, and similarly a certain number of lines of force threading the secondary winding do not thread the primary winding. This means that each winding possesses a certain inductance of its own, and on this account a certain E.M.F. will be required to overcome the inductance voltage created in each winding when the transformer is working under load. Before answering this question it will, perhaps, be as well to investigate the working of a transformer possessing magnetic leakage and working under load. This can be best understood by aid of the vector diagram, shown in Fig. 1. For simplicity the assumption is made that the ratio of transformation of the transformer is unity, and that the load is non-inductive. Here we have O i_2 = secondary current; O E_2 = E.M.F. at the secondary terminals; E_2 e_2' = ohmic drop in secondary winding; O e_{s2} = E.M.F. required to overcome the inductance of secondary, drawn at right angles to O i_2. Then O e_2 = resultant of O e_2' and O e_{s2} is the E.M.F. induced in the secondary winding.

Again, O i_μ = wattless magnetising current, obviously at right angles to O e_2; O i_h = current required to compensate for the iron losses, drawn at right angles to O i_μ. Then O i_k = the resultant of O i_μ, and O i_h is the no-load current. This current must be the resultant of the primary and secondary currents, so that the secondary current, O i_1, is readily determined.

Further, O *b* = ohmic drop in the primary winding; O e_{s1} = E.M.F. required to overcome the inductance of the primary winding, at right angles to O i_1. Obviously, the E.M.F. applied to the primary terminals must be the resultant of O *b*, O e_{s1}, and a third component, O e_1, drawn equal and opposite to O e_2. The resultant O E_1 is then the E.M.F. across the primary terminals. This diagram

Digitized by Google

can be greatly simplified in construction by assuming that the magnetising current, i_μ, is negligible, which is very nearly the case in practice, so that the primary and secondary currents are exactly opposite in phase to one another.

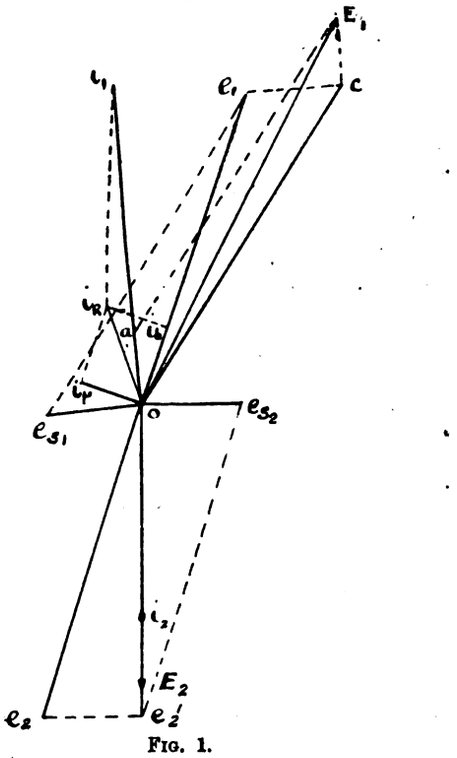

FIG. 1.

Fig. 2 shows the reconstructed diagram, it further being assumed that the load is now inductive, such that the angle of lag of the secondary current is ϕ. The same lettering is used as in Fig. 1; the ohmic drop in the primary winding (m E_1) being taken as equal to that in the secondary (E_2 e_1'), and similarly the inductance E.M.F.

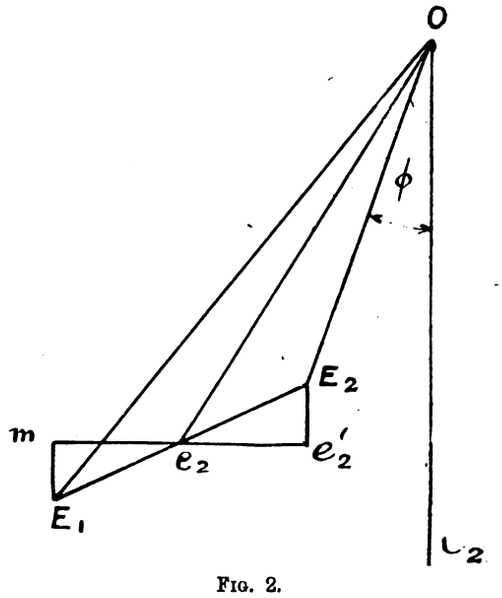

FIG. 2.

in the primary m e_2 equal to that in the secondary e_2 e_2'. O E_2 is then the secondary E.M.F. corresponding to a primary voltage, O E_1. This diagram can be still further simplified and brought into a form from which the primary and secondary voltages can be at once derived for any lag or lead of the secondary current with the transformer fully loaded.

Fig. 3 shows the practical form in which O A is equal to E_1 E_2 in Fig. 2, and A B represents the total ohmic drop in both windings, or twice that in either winding. About O as centre a circle is described of radius O E_1, where O E_1 is the constant E.M.F. applied to the primary terminals. With the same radius another circle is described with A as centre. Now consider the case where the vector representing the primary voltage has the position O E_1'. This corresponds to a non-inductive load on the secondary, there being neither lag nor lead of the secondary current. The secondary voltage is then represented by the length of the vector O E_2', E_1' E_2' representing the combined leakage and ohmic drop in the secondary. Suppose the load is inductive, and that the angle of lag is ϕ. Then, again, the primary voltage is represented by O E_1, and the secondary voltage by O E_2, and, similarly, the secondary voltage can be obtained for any value of the angle ϕ. In the case where the secondary current leads by an angle ϕ', the secondary voltage is here represented by O E_2'' and the primary voltage by O E_1'', and it is seen that the secondary voltage exceeds the primary voltage by an amount E_1'' E_2''.

The above has not truly answered the question, for before any practical use can be made of the diagram, it will be necessary to determine the value of O A. A B, of course, can be calculated from a knowledge of the full-load secondary current and the resistance of either winding. The value of O A is readily determined in the following manner. Short-circuit the secondary winding through an ammeter of negligible inductance (a hot-wire instrument for preference), and then apply current to the primary winding until the full-load secondary current is indicated on the ammeter. The voltage drop across the primary winding then represents the value of O A. This can be readily seen to be the case by a reference to Fig. 2. If this diagram was redrawn to suit the above case, O E_2

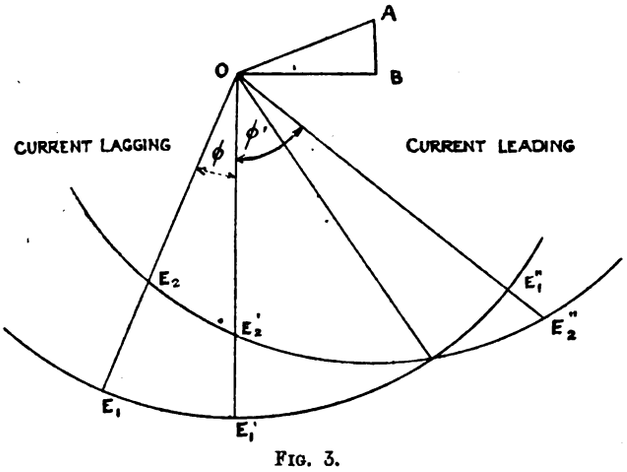

FIG. 3.

would obviously be zero, so that E_2 would coincide with O, and the primary voltage O E_1 would be equal to E_2 E_1, which latter corresponds to O A in Fig. 3.

In all the above cases it has been assumed that the ratio of transformation is unity, but Fig. 3 can be applied to a transformer with any known ratio simply by reducing the primary voltages to equivalent secondary voltages. To illustrate this, let us take the case of, say, a 60-kw. transformer, ratio 3,000 volts primary, 200 volts secondary.

Suppose resistance of primary = 1 ohm, then ohmic drop at full load = 1 × 20 = 20 volts.

Again, resistance of secondary = ·004 ohm, ohmic drop at full load = ·004 × 300 = 1·2 volts. Reducing the ohmic drop in the primary to correspond to a ratio of unity, we get a drop of $\left(20 \times \frac{200}{3{,}000}\right)$ = 1·33 volts. Therefore, total ohmic drop in both windings = 2·53 volts, corresponding to a ratio of unity.

Suppose that to maintain the full-load current of 300 amperes through the short-circuited secondary winding a voltage of 270 volts had to be applied to the primary terminals. This corresponds to a reduced voltage of $\left(\frac{270 \times 200}{300}\right)$ = 18 volts. Therefore, referring to Fig. 3, we have O A = 18, A B = 2·53, O E_1 = 200. If these be drawn to scale, the secondary voltage for any lag or lead of the secondary current can be at once scaled off.

I presume "R. S. L." requires to know the drop due to leakage alone. This for the case where the angle of lag is ϕ will be (E_1 E_2 − A B), and similarly for any other position.—A. P. YOUNG.

Answer to No. 732 (*awarded* 5*s.*).—An easy method of determining the drop in secondary volts of a transformer at full load and at any power factor is the following First find the maximum impedance drop in the two windings. This can be found experimentally by short-circuiting the secondary coil and measuring the pressure across the primary terminals when full-load current flows through the windings at the working frequency. Fig. 1 is a sketch

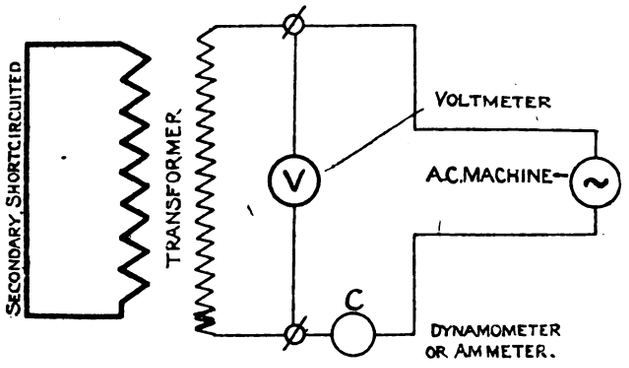

FIG. 1.

showing the connections necessary for this test. If C = the full-load current of the transformer, then V = the maximum impedance volts referred to the primary, and $\frac{V}{K}$ = the maximum impedance volts referred to the secondary, where K = ratio of transformation.

$$\frac{V}{K} = \sqrt{(\text{inductive drop})^2 + (\text{ohmic drop})^2}.$$

The drop in volts due to resistance of windings = $C_1 \times R_1 + \frac{C\ R}{K}$ = ohmic drop; C_1 = secondary full-load current; C = primary full-load current; R_1 = secondary resistance; R = primary resistance.

Knowing the full-load currents of the transformer, and finding the resistances of the windings, either by calculation or experiment, the ohmic drop at full load is easily determined. Construct a triangle A B C, making A B = impedance volts referred to secondary; B C = ohmic drop in secondary volts to a convenient scale; and the angle A C B a right angle. To the same scale, with radius equal to the

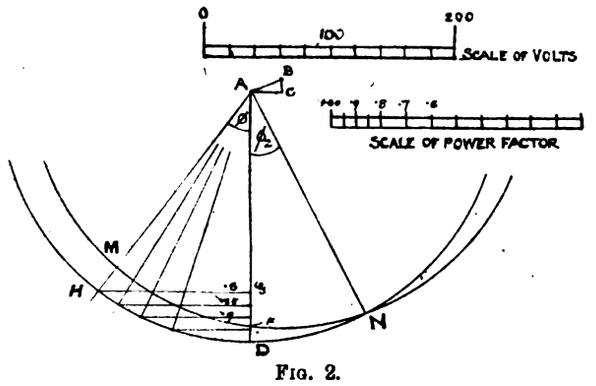

FIG. 2.

secondary voltage at no load, draw two circles with centres at A and B. Draw line D A at right angles to A C, then the length D F, to scale, cut off by the two circles is the total drop in secondary pressure at non-inductive full load. If the current lags by an angle ϕ—*i.e.*, if the power factor of the secondary load = cos ϕ—draw A H, making angle D A H = ϕ, then total drop in secondary volts at full load (power factor = cos ϕ) is the length H M, to scale. Now, $\cos \phi = \frac{A\ G}{A\ H} = \frac{A\ G}{A\ D}$. Therefore, if the line A D be divided into decimal parts, the position of the line A H for any power factor can easily be found by completing the triangle A H G, H being the point of intersection of the perpendicular H G drawn from G, and the circle centred at A. The angle ϕ_2 is drawn on the opposite side of line A D when the current leads by this amount. It is seen that the circles intersect at N. A N equals A D; therefore, when current leads by angle ϕ_2, there is no drop in secondary volts; if the angle of lead is greater than ϕ_2, then secondary volts rise.

For the sake of clearness, the triangle A B C in the diagram (Fig. 2) is shown larger in proportion to A D than in an ordinary transformer diagram—*i.e.*, constant-potential lighting transformer. In this diagram impedance volts = A B = 25 volts; ohmic drop = B C = 10 volts; total drop at power factor 1 = 12·5 volts, ·95 = 20 volts, ·9 = 22 volts, and ·85 = 23 volts. Working out a diagram for an actual transformer of which the following data are known: kilowatts = 50; primary volts, 2,000; secondary volts (no load), 204; primary resistance, ·5; secondary resistance = ·05; ~, 50; impedance volts (secondary), 10; total ohmic drop (secondary) = 2·5, the total drop at various power factors: 1 = 3; ·95 = 5·5; ·9 = 6·5; and ·85 = 8. The drop due to magnetic leakage alone = total drop − ohmic drop.—W. H.

THE AUSTRALIAN TELEGRAPH SYSTEM.

Hugh H. Lusk, in the November number of the *North American Review*, describes the Australian telegraph system. Before the Australian States were welded into one commonwealth, each of the States owned and controlled the telegraph lines within its borders, but when the union was effected the Federal Government took over all telegraph lines, and the Federal Parliament established the conditions under which they should be operated. Rates were fixed for town and suburban messages, for messages from one point to another point within the same State, and for messages from a place in one State to a place in any other State within the Commonwealth, and, taking these together, Mr. Lusk asserts that the cost of telegraphing in Australia is less than one-half, and would probably work out at one-third, the amount charged in America. The combined cheapness and efficiency of the telegraph system in Australia Mr. Lusk attributes to the fact that the telegraph lines are owned and operated by the public, and to the economies naturally attending the system. That the public utilise the facilities thus afforded them for telegraphic communication is evident from the fact that the number of messages *per capita* in Australia is apparently nearly three times what it is in America. The differences appear due, however, quite largely to methods of counting. He says:

"The circumstances of Australia, and the conditions of its settlement, have had the effect of making both its railroads and its telegraphs unusually extensive in comparison with the numbers of its population, and this is markedly the case with its mileage of telegraph lines. At present the great island is only settled on a strip of country bordering on the coast, and even that strip does not include the more northern shores either on the east or west, and takes in no part of the north side at all. The consequence is that a line of telegraph which connects the settlements of Queensland on the north-east of Australia with those of West Australia on the west coast—a distance, in a direct line, of about 2,500 miles—covers fully double that distance from the necessity of keeping in touch with the settled districts. There is, indeed, one line of telegraph which of necessity ignores this rule, and passes for nearly its whole length of about 1,700 miles from the south to the north-western corner of the island through an unsettled country. The purpose of this line is to connect settled Australia with the rest of the world by way of Java and India, and it passes through great districts of the interior which were first explored for the purpose of its construction. Under the circumstances, it was not possible that telegraph facilities could be supplied in Australia on a small scale or at a trifling cost."

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

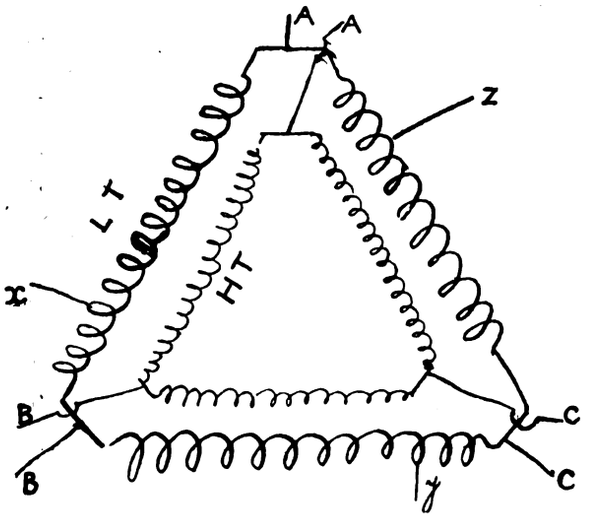
QUESTIONS.

741. A private telephone used in connection with a certain tramway system, to speak from the generating station to the different section boxes along the line, is found to work very unsatisfactorily when the cars are running, but works well when the cars have been stopped. The noise of cars can be heard quite distinctly, so much so that it is impossible to hear what is said. Length of track about seven miles; the telephone cables are laid beside the traction feeders, but in a separate trough, and parallel to the track. What is the best remedy to overcome this difficulty?—G. M.

742. It is common practice in continuous-current designing to take the permissible reactance voltage (per section of the armature winding) at a higher figure in the case of motors than in the case of dynamos. Is there any basis for this procedure in point of fact or of theory? Please discuss fully.—F. W. D.

ANSWERS.

733. In a three-phase sub-station for rotary converters, the three single-phase transformers are connected in mesh. From each of these transformers an extra lead is taken on the low-tension side



to provide a lower voltage for starting the starting motors of the rotaries. In what phase are these extra leads—x, y, and z?—POLYPHASE.

Answer to No. 733 (*awarded* 7*s.* 6*d.*).—If the leads x, y, and z are taken off the secondary windings at exactly symmetrical positions—*i.e.* the number of turns between the points B x, A z, and C y are equal—then the voltages between the lines x, y, and z will be equal and exactly 120deg. apart in phase to one another. This can be easily seen by reference to Fig. 1. In this diagram 0 1 represents the voltage across the secondary winding, C B, 0 2 that across B A, and 0 3 that across the third winding, A C. Now, the voltage between the lines x and y is made up of two components, one component proportional to the winding between the points B and y and in phase with 0 1, the other component proportional to the winding between the points B and x and in phase with 0 2. The resultant of these two components represents the voltage between the lines x and y, and is represented in magnitude and phase by the vector $0\,y\,x$ in the diagram. Similarly the voltage between the lines x and z is represented by $0\,x\,z$, and that between the lines y and z by $0\,z\,y$ From the symmetry of the diagram it is easily seen that if the winding between the points B x, A z, and C y are equal, then the three vectors $0\,y\,x$, $0\,x\,z$, and $0\,z\,y$ will be equal and exactly 120deg. apart in phase.

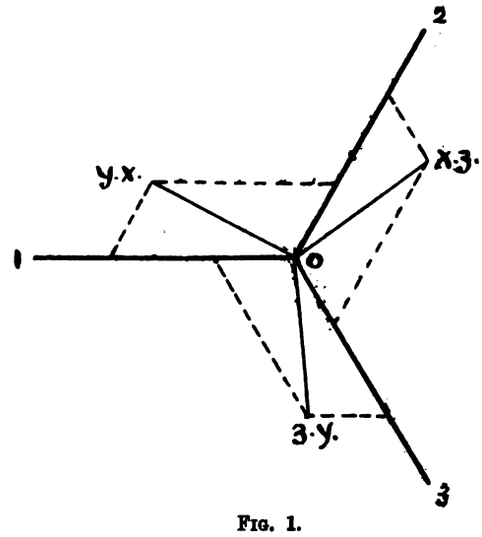


FIG. 1.

The state of affairs can be more readily seen by a reference to Fig. 2. Here the triangle A B C represents the voltages across the three secondary windings. The triangle $x\,y\,z$ then represents the voltages between the lines x, y, and z, and obviously this triangle is an equilateral triangle. From this diagram it is readily seen that the minimum voltage that can be obtained between the lines x, y, and z still maintaining 120deg. phase displacement between the three voltages is one half the

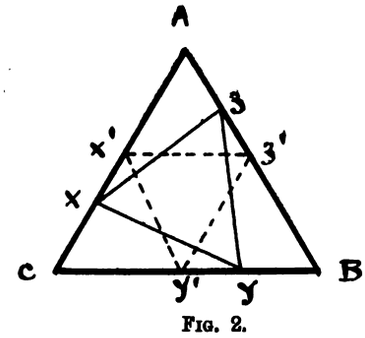

FIG. 2.

voltage across the secondary of either transformer, corresponding to the dotted triangle, $x^1\,z^1\,y^1$, and it is seen that this result is obtained by tapping off the secondary windings at the points $x^1\,z^1\,y^1$—*i.e.*, at the middle point of each.—A. P. Y.

Answer to No. 733 (*awarded* 7*s.* 6*d.*).—To find the phases of the voltages between the points X, Y, and Z, the easiest way is to use the graphical method. The diagram to be drawn is similar to that given by "Polyphase" in his question, except that the lines now represent E.M.F.'s instead of actual transformer windings. We need not consider the primaries of the transformers. The secondaries being connected in mesh, their E.M.F.'s will be represented by an equilateral triangle, A B C (Fig. 1). If the triangle revolve about its centre point, O, in, say, a clockwise direction, the projections of A B, B C, and C A at any instant on the horizontal, P Q, will give their respective instantaneous values at the instant in question. Similarly, the projections of O A, O B, and O C give the instantaneous values of the E.M.F.'s between A B C and the neutral.

Digitized by Google

Now, take points X, Y, and Z in A B, B C, and C A respectively such that these points divide the three lines in the same proportion that the secondary windings are divided by the tappings. Then the triangle X Y Z obviously must represent the E.M.F.'s between these points, and their instantaneous values will be given by the projections of X Y, Y Z, and Z X upon P Q. Also the phases of the voltages between these extra leads relatively to the phases of the main voltages, A B C, will be given by the angle θ.

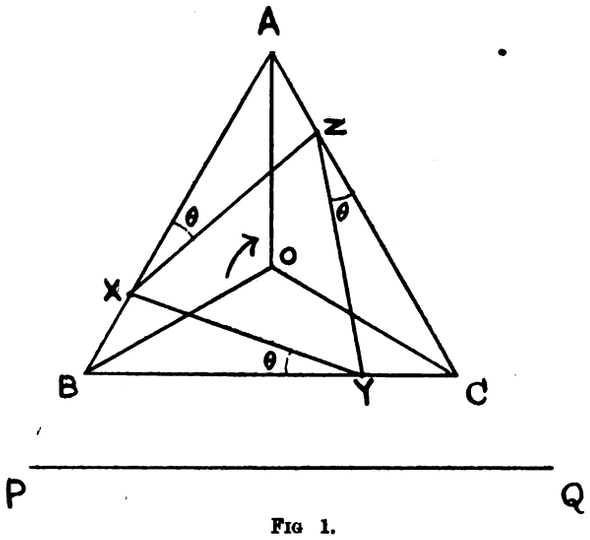

FIG 1.

This is clearly so, because X Z reaches its maximum—*i.e.*, is parallel to P Q—before A B by an interval equal to the time taken to turn through an angle θ. The question does not give the positions of X, Y, and Z in the windings, but if we assume A X = two-thirds of A B, and the other windings to be similarly divided, it is easy to show that the starting voltage on the motor is 58 per cent. of the full voltage, and differs in phase from the latter by an angle of 30deg. If X, Y, and Z are taken at the middle points of A B, B C, and C A respectively, then the starting voltage is obviously one-half, and differs in phase from the main voltage by 60deg.

An easier method of connection for accomplishing the same result is shown in Fig. 2. Two of the secondary windings only, A B and A C, are tapped at X and Y, and

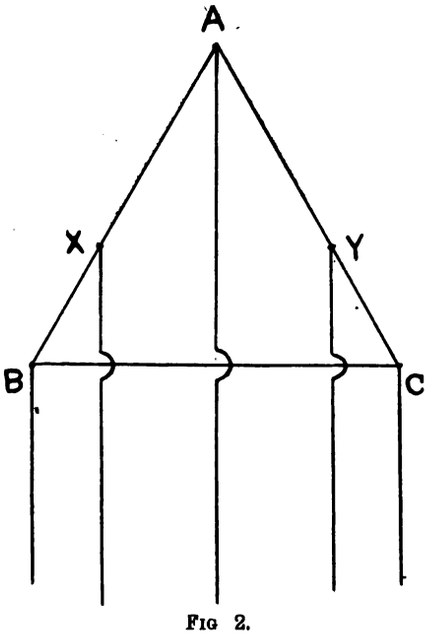

FIG 2.

extra leads taken from these points. The starting voltage is given by the leads from A, X, and Y, and the running or normal voltage by the leads from A, B, and C. This allows of running only two extra leads for starting. The secondary, B C, is idle, and the voltage regulation not quite so good as if all three were used, though quite good enough for starting purposes.—R. C.

Answer to No. 733 (*awarded* 5*s.*).—In order to determine precisely the phase angle between the E M.F. wave at x, y, and z and the E.M.F. wave in the high-tension lines connected to B, C, and A respectively, we must investigate the various reactions taking place in the transformer itself. Since the transformers are separate in each phase, the phase of the volts across B x and B A will be identical. Hence, if we find the phase of this latter E.M.F., we shall arrive at the determination required.

Let us consider the initial case of an unloaded transformer. Let E_{11} (Fig. 1) represent the phase of the secondary E M.F., B A. Since no current is flowing in the

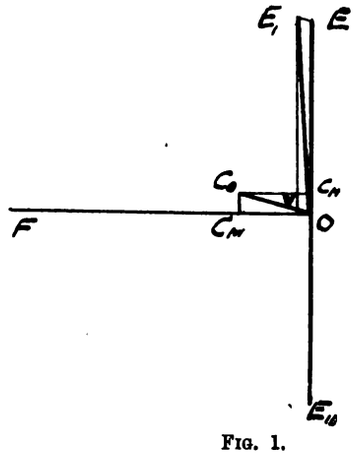

FIG. 1.

secondary windings, we have no losses, and hence E_{11} represents the induced secondary volts. The alternating flux producing this leads by 90deg., and may be represented by F. A back E.M.F. in the primary is also induced by this flux, and is shown as E (leading again by 90deg.).

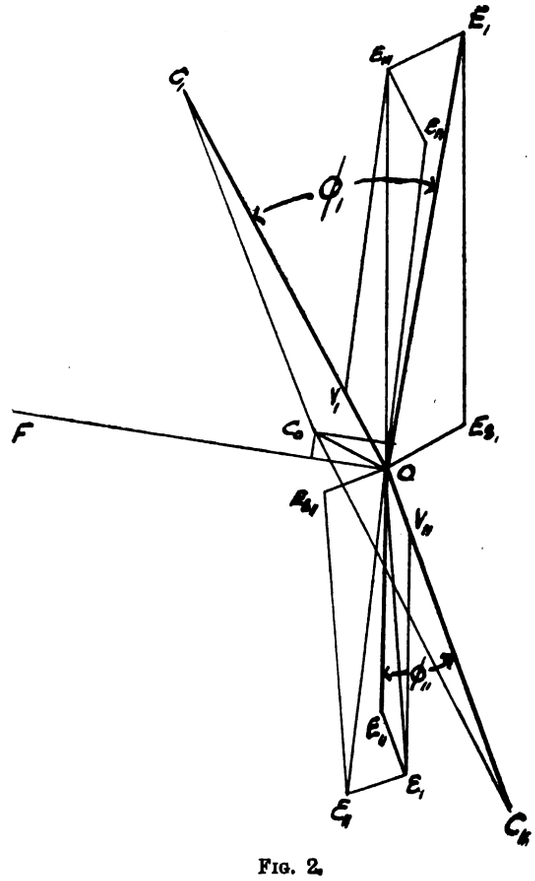

FIG. 2.

A small current flows in the primary of the transformer supplying the iron losses and magnetising the transformer. The magnetising component, C_M, is in phase with the flux, and the hysteresis, etc., losses are made good by C_H in phase with the E M.F. (power component). C_0 then is the no-load current. V is a vector equal to the volts lost in the primary due to C R drop. Hence, E_1—the resultant of E and

Digitized by Google

V—gives the phase of the line volts—at least the high-tension potential difference across the primary. The angle E_1 O E_{11} is a measure of the phase displacement of the volts B A (or B x) and the primary terminal potential difference.

When a load comes on the transformer, the conditions are not so simple. For the sake of discussion we will assume a load current, C_{11}, lagging behind the E.M.F., E_2, by the angle ϕ_{11}. Now the resistance of the secondary caused a voltage loss equal, say, to V_{11}. Further, owing to a small amount of magnetic leakage between the secondary wires, we have a self-induction E.M.F. lagging 90deg. behind the current wave. This effect is dependent on the frequency and the number of turns on the secondary coil and the leakage coefficient, which varies with different types of transformer. This must be allowed for by a vector, E_{s11}, in opposition, and so shown leading by 90deg. Now, compounding these three E.M.F. vectors, E_{11}, V_{11}, and E_{s11}—we get first E_1, then E_{11}—which is the total induced secondary volts necessary to give the current C_{11} at a terminal voltage of E_{11}, lagging by ϕ_{11} degrees. As before, we need a flux F, 90deg. in advance, giving in its turn a back E.M.F., E_{1V}. C_o is the current necessary for magnetisation and iron losses. To get, C_1 the primary load current, we proceed as follows: C_{11}, in addition to producing the small self-inductive field, would also produce another field in phase with this latter, were it not prevented by the tendency of the primary current to produce a field equal to it but in opposition of phase. Hence the phase of the primary load

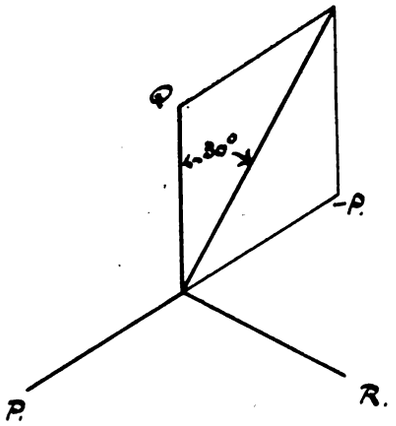

FIG. 3.

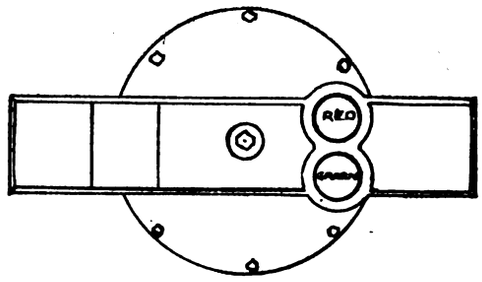
current—that is to say, that component which neutralises the effect of the secondary load current—is in opposition of phase to C_{11}, whence by compounding we obtain C_1, the primary current. The component parts of the total primary volts are: (1) the back E.M.F., E_{1V}; (2) the self-induction neutralising E.M.F., E_{s1}; (3) and the primary copper drop, V_1. These when compounded give E_1, the terminal primary volts. The angle between E_1 and E_{11} is a measure of the phase angle between volts B A primary and B A secondary. If the vectors P Q R in Fig. 3 represent the phase of the volts generated in each coil or winding of the star-wound alternator (usual tramway, etc., practice), then if P and Q represent the waves at A and B respectively, evidently the phase of the potential difference on A B (primary) will be 30deg. in advance of the alternator wave. Therefore, the phase of the voltage across B x (or A x for that matter) will be E_1 O E_{11}—30deg. This angle, as will be seen from a study of the diagram, changes with the load current and the power factor, and also with the frequency.—W. E. O.

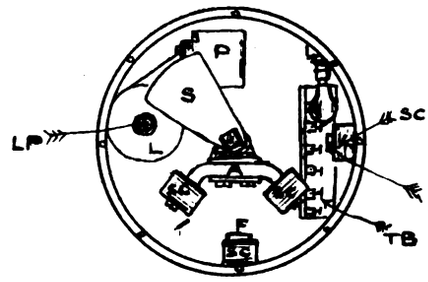
Question No. 734.—Describe the Harison system of electric signalling for single-line working on tramways.

Answer to No. 734 (*awarded* 7*s.* 6*d.*).—The Harison system is automatic and simple. It is arranged on the lock and block principle; only one car is allowed on the protected section at the same time. It also provides for the contingency of two cars entering the protected section simultaneously from opposite ends. The signals consist of miniature railway semaphores, with red and green spectacles, illuminated at night by incandescent lamps. The semaphore arm is weighted so as to return from the "line clear" position to "danger" entirely by gravity, thus complying with the Board of Trade regulations. On a current being passed through the signal coils, S C, the armature, A, carrying the semaphore arm is attracted by the fixed pole-pieces, F, thereby lowering the arm to the "safety" or "line clear" position. The arrangement for locking the arm at the "danger" position and unlocking the same is accomplished by two solenoids provided with a common plunger, L P. When current is passed through the front (or locking) solenoid, L, the plunger is drawn into it, and engages with the "shield," S, on the shaft carrying the arm,



View of Signal with Arm and Lid in Position.

thereby preventing it from lowering. When a current is allowed to pass through the rear (or unlocking) solenoid, the plunger is drawn back into it, and disengages from the shield, and the arm is left free to lower. The preference solenoid, P, is provided in one only of the two signals protecting a section. This is a device for preventing the preference signal from being locked, and comes into action



View of Signal with Arm and Lid removed, showing position of Mechanism when Signal is at Danger. S C Signal coils, A Armature, F Fixed pole-pieces, L P Locking plunger, S Shield, L Locking solenoid, P Preference solenoid, T B Terminal board.

when two cars are trying to enter the protected section at opposite ends at the same instant. It has no effect if the preference signal is already locked. The mechanism of the signal proper is, therefore, extremely simple, there being no electrical contacts to wear, spark, or get out of order, so that the maintenance is practically nil. The whole of the working parts are enclosed in a cast-iron watertight case, with a small door in the lid for inspection purposes. The installation can be carried either on the shunt or series system, both being applicable to single trolley lines.

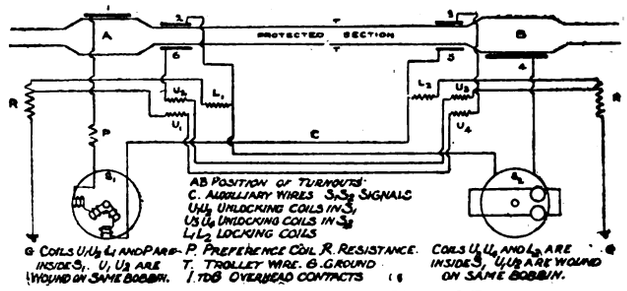


Diagram of Shunt System—Single Line and Turnout.

Diagrams of connections are shown for the shunt system arranged for a single line and turn-outs. For this six overhead contacts are erected, shown at 1, 2, 3, 4, 5, and 6. Contacts 1 and 4 are arranged so that a car always stops underneath them while waiting on the turnout, the remaining contacts being placed so that there is no possibility of a car stopping underneath them. Suppose a car arrives at A and makes contact with 1, the P, S_1, and L_2 to earth is completed. If this line is clear, S_1 is lowered and

Digitized by Google

S_2 is locked. The car then proceeds to 2, where the circuit made is L_1 to earth, thereby locking S_1 behind it, the line being now blocked. When the car arrives at 3 the circuit U_4 U_1 to earth is made, and both signals are unlocked. The operations of 4, 5, and 6 contacts are identical with 1, 2, and 3 respectively. It will be noted that 3 and 6 are provided with separate unlocking circuits, which can never be alive at the same time. The windings of the solenoids are so arranged that (1) if U_1 and L_1 are both energised, S_1 remains unlocked; (2) if U_2 and L_1 are both energised, S_1 is unlocked; (3) if U_3 and L_2 are both energised, S_2 remains unlocked; (4) if U_4 and L_2 are both energised, S_2 is unlocked. Also, if L_1 and L_2 are dead, U_1, U_2, U_3, and U_4 are each of themselves capable of unlocking their respective signals.

Bearing these facts in mind, the following cases are taken to show the action of the signal: (1) if car A reaches 1 before car B reaches 4, S_1 is lowered and S_2 locked, or *vice versâ*; (2) if cars A and B arrive at 1 and 4 simultaneously, S_2 is locked, but not S_1, since the preference coil prevents it, car A thereby having the preference; (3) if cars A and B are waiting at 1 and 4 respectively, and a third car, C, is on the protected section, the signal at which it arrives will be unlocked, but not the one behind it.

It is unnecessary to describe the series systems in equal detail here. Suffice it to say that it is so termed on account of the signal windings being in series with the overhead trolley wires, an arrangement which involves the erection of a few section insulators and the use of two auxiliary wires. The chief advantage claimed for the Harison system of automatic signalling over other systems of its kind is that it provides for the contingency of two cars on a single-line system trying to enter the protected section from opposite ends simultaneously. The system is being used at Portsmouth, Batley, Wallasey, etc.—C. H. L.

Answer to No. 734 (*awarded* 7*s.* 6*d.*).—The Harison patent system of automatic signalling for single-line working of tramways is so arranged that a shunt or series system may be used, but as the series system has not so far been used, I propose to confine my remarks to the shunt system. The signal, as shown in Fig 1, is arranged with a semaphore

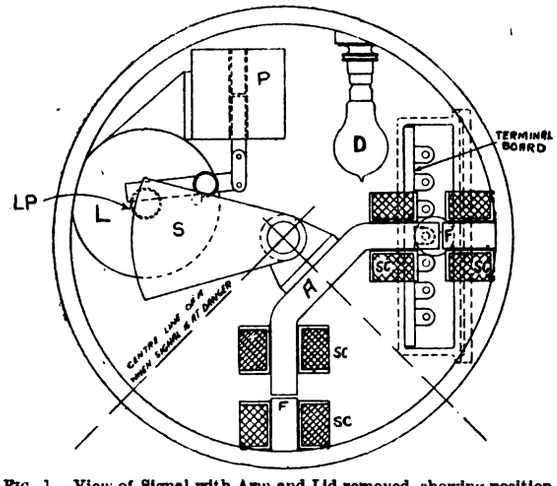

FIG. 1.—View of Signal with Arm and Lid removed, showing position of Mechanism when Arm is at "Line Clear" Position.

fitted with red and green spectacles, which are illuminated at night by incandescent lamps, marked D. This semaphore arm is weighted so as to return from the "line clear" position to "danger" entirely by gravity. On a current being passed through the signal coils, S C, the armature, A, carrying the semaphore arm, is attracted by the fixed pole-pieces, F, thereby lowering the arm to the "safety" or "line clear" position. The arrangement for locking the arm at the "danger" position, and unlocking the same, is accomplished by two solenoids provided with a common plunger, L P. When current is passed through the front or locking solenoid, L, the plunger is drawn into it, and engages with the shield, S, on the shaft carrying the arm, thereby preventing it from lowering. When a current is allowed to pass through the rear or unlocking solenoid, the plunger is drawn back into it and disengages from the shield, and the arm is left free to lower. The preference solenoid, P, is provided in one only of the two signals protecting a section. It is a device for preventing the preference signal from being locked, and comes into action when two cars are trying to enter the protected section at opposite ends at the same instant. It has no effect if the preference signal is already locked, nor till it is unlocked. The whole of the working parts are enclosed in a cast-iron watertight case, which is arranged to bolt on to the traction poles.

When the shunt system is used, the diagram of connections for which is shown in Fig. 2, it is necessary to have

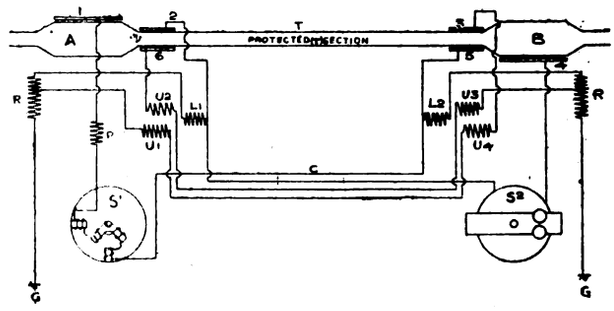

FIG. 2.—A B Turnouts, C Auxiliary wires, S_1 S_2 Signals, U_1 U_2 Unlocking coils in S_1, U_3 U_4 Unlocking coils in S_2, L_1 L_2 Locking coils, G Ground, P Preference coils, R Resistance, T Trolley wire, 1 to 6 Overhead contacts.

erected special contacts (overhead), which are operated by the trolley wheel or trolley head. Connection is made between the trolley wire and the overhead contact, and the shunt circuit is established through the signals to earth during the time that the car is under the contacts. Four auxiliary leads are also required between the signals, these being of small cross-section, the amount of current used being about 2½ amperes. Fig. 2 shows the special overhead contacts, which are marked 1, 2, 3, 4, 5, and 6. Contacts 1 and 4 are arranged so that a car always stops underneath them whilst waiting on the turnout. Contacts 2, 3, 5, and 6 are placed so that there is no possibility of a car stopping underneath them. Suppose a car arrives at A and makes contact with 1, the circuit completed is P, S_1, and L_2 to earth. If the line is clear, S_1 is lowered and S_2 is locked. The car then proceeds to 2, where the circuit made is L_1 to earth, thereby locking S_1 behind it. The line is now blocked. When it arrives at 3 the circuit made is U_4, U_1 to earth, and thus both signals are unlocked. The operations of numbers 4, 5, and 6 contacts are identical with numbers 1, 2, and 3 respectively. Now, it will be noticed that 3 and 6 are provided with separate unlocking circuits, which can never be alive at the same time. The windings of the locking and unlocking solenoids are so arranged that if U_1 and L_1 are both energised, S_1 remains locked; if U_2 and L_1 are both energised, S_1 is unlocked; if U_3 and L_2 are both energised, S_2 remains locked; and if U_4 and L_2 are both energised, S_2 is unlocked; also if L_1 and L_2 be not energised, U_1, U_2, U_3, and U_4 are each capable of unlocking their respective signals by themselves.

Bearing these facts in mind, the following cases are taken to show thoroughly the action of the signal: (1) Suppose car A reaches 1 before car B reaches 4, S_1 is lowered, S_2 is locked. (2) If car B reaches 4 before car A reaches 1, S_2 is lowered and S_1 is locked. (3) If cars A and B arrive at 1 and 4 simultaneously, S_2 is locked but S_1 is not, since the preference coil prevents it, car A thereby having the preference over car B. (4) If car A and car B are waiting at 1 and 4, and a third car, C, is on the protected section, then if car C arrives at 3, S_2 is unlocked but not S_1. If, however, car C is going in the other direction and arrives at 6, S_1 is unlocked and not S_2.—B. C. S.

[Other replies to Question No. 734 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

743. I use five tons of zinc annually in the production of hydrogen for plumbers' use. When the solution is saturated with sulphate of zinc it is thrown away. Describe best method of recovering the zinc in metallic form by electrolysis.—G. W.

744. Will anyone who has had experience with the Cruse controllable superheater give an account of its general working as regards efficiency, cost of upkeep, and the liability of the copper water-tubes to become scaled or corroded?—S. T.

ANSWERS.

Question No. 734.—Describe the Harison system of electric signalling for single-line working on tramways.

Answer to No. 734 (*awarded* 5*s.*).—The Harison signal for single-line tramways with turnouts is constructed in two forms—viz., shunt and series—but a description of the shunt will serve for both, as it will give a general idea of the system. The apparatus consists of a number of overhead contacts (1-6, Fig. 3) placed in close proximity to the trolley wire, signals constructed as shown in Figs. 1 and 2, with semaphore arm and red and green glasses for night use (an incandescent lamp being used to illuminate the glasses), and four auxiliary wires between each turnout. The semaphore arm is weighted so that it will return to "danger" by gravity alone, thus complying with the Board of Trade regulations. The current for working the apparatus is obtained from the trolley wire by means of an attachment on the trolley head, which makes a connection between the trolley wire and fixed contact pieces. The connections are shown in Fig. 3. On a current being passed through the signal coils, D_1 D_2, the movable coils, D_1, mounted on the armature, E, are attracted towards the fixed pole-pieces, D_2, thus lowering

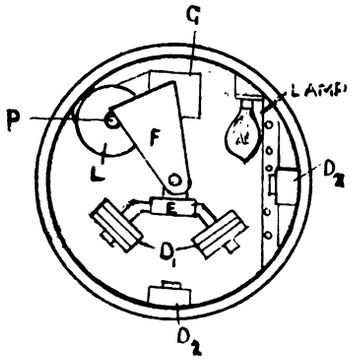

Fig. 1.

the arm to "clear." The semaphore arm is locked by the aid of three coils—L (the locking coil) and two unlocking coils, U_1 U_2—mounted side by side with one common plunger, P. When current is passed through the front coil, L, the plunger is drawn into it, the front end projecting and preventing the arm, F, from lowering, thus locking the semaphore arm at "danger." On current being passed through unlocking coils the plunger is withdrawn, thereby unlocking the arm. The preference coil, G, is provided in one of the two signals controlling a section, which gives preference to the signal in which it is placed, when two cars try to enter the section at the same time in opposite directions, the preference coil preventing its signal being locked. Suppose a car arrives at A, if the signal S_1 is not locked, current passes through G, S_1, L_2,

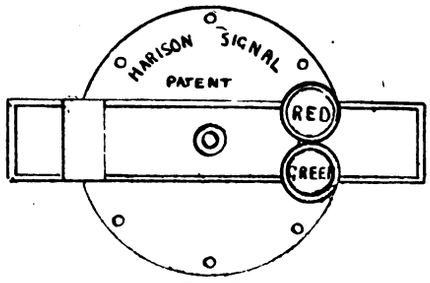

Fig. 2.

and r_2 to earth, thus lowering S_1 and locking S_2. When car leaves 1 the signal S_1 returns to "danger," and is locked by current from 2 through L_1 and r_1 to earth. On arriving at 3, S_1 and S_2 are both unlocked, thus leaving line clear. The windings are so arranged that if U_1 and L_1 are both energised, S_1 is locked; if U_2 and L_1, S_1 is unlocked; if U_3 and L_2, S_2 is locked; and if U_4 and L_2, S_2 is unlocked.

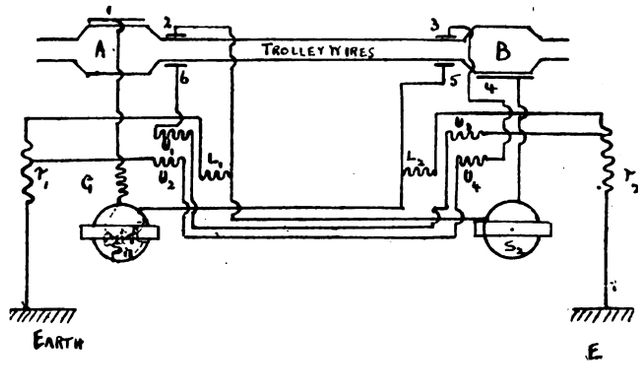

Fig. 3.

The current required to work the signal is from two to three amperes, so that small cross-section wires only are required. The signals are fixed on the poles which support the trolley wire. In the series system a few section insulators are required in the trolley wire, the current being passed through the signals to the cars and two auxiliary wires.—H. S.

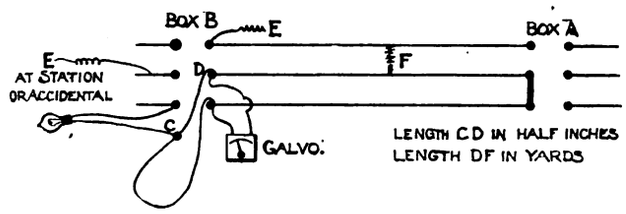
Question No. 735.—What is the most practical (not text-book) method of quickly locating faults in underground three-core lead-covered distributors (laid solid) or concentric feeders (in conduits) on a three-wire continuous-current system? Consider the following faults: (1) two cores short-circuited; (2) two cores short-circuited with "earth"; (3) earth on one core (unusual). It is required—first to quickly locate between disconnecting boxes, and then locate closely. The writer (for the latter) favours a simple system with comparatively large testing currents, such as taking drop of potential from each end of faulty main to earth, with heavy constant current passing along whole main, but fails to see how this method can be applied in the cases of (1) and (2). Accurate bridge tests, in the writer's opinion, are almost impossible for street work. Give particulars of most suitable instruments and apparatus that can be quickly arranged for tests.

Answer to No. 735 (*awarded* 7*s.* 6*d.*).—First, to locate between disconnecting boxes. It may be assumed that in (1) and (2) considerable current is flowing through the fault, and we may test in each disconnecting box, without disconnecting, by placing a small compass on the connecting links and noting the direction of the current. We can thus trace up to the nearest disconnecting box to the fault, since in the core which is positive to the fault the current must be flowing towards the fault; and in the negative core, away from the fault. If the leakage current be small compared with the load, or in case (3), the only satisfactory method is to "disconnect and try." Trying or testing is most quickly done by using a lamp as detector, and poten-

Digitized by Google

tial to earth from the mains. With 200 volts to earth, a 200-volt 8-c.p. lamp will show a red filament when in series with a fault of 5,000 ohms resistance. In cases (2) and (3) the cable to be tested is disconnected at both ends, one lamp lead connected to a terminal in the box at, say, 200 volts to earth; the other lamp lead is touched to "earth," and the lamp lights up, then touched on the terminal of the core to be tested, and if the filament of the lamp shows no colour, the insulation resistance of that core is over 5,000 ohms to earth. A similar test for "circuit" instead of for "earth" is made in case (1). If all three cores are not dead while one is being tested, care must be taken that any colour shown on the lamp filament is not due to consumers' lamps connecting the "dead" core under test with the "live" one.

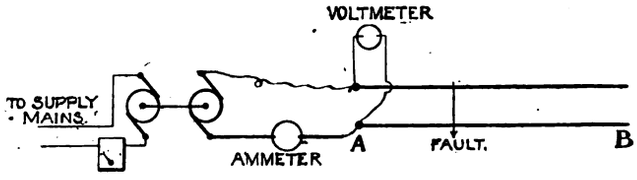
Secondly, to localise on a continuous length. I beg to disagree with "R. V. M." I have found the "loop test" most accurate, and the three cases he gives lend themselves particularly to that method of localisation. The only instrument required is a low-resistance moving-coil galvanometer giving a visible deflection with ·0001 volt applied to its terminals. Such an instrument can be obtained for about £7. My method of testing may be best shown by an example. Suppose the fault to be between two disconnecting boxes, A and B, the length of cable between terminals being exactly 100 yards, and the section of each core ·25 square inch. Throw dead all three cores. In box A make a good short-circuit connection between the good core and a faulty one. For this connection I use tin fuse strip 1in. by $\frac{1}{16}$in., which, if cleaned and clamped on to a clean terminal is bound to "bed" well and make good connection. The resistance of this must be calculated or measured, and is found to be equal to that of, say, 30ft. of ·25 square inch cable. This gives the total equivalent length of loop (box B to box A) connector (box A to box B), 100 + 10 + 100 = 210 yards. For the balance wire, take a scale of $\frac{1}{2}$in. of balance wire to a yard of cable loop; 210 half-inches = 8ft. 9in., a convenient length for working. The resistance of this should be comparable with that of the cable loop; No. 16 or No. 18 copper binding wire will do very well, but it must be free from bad kinks, which are apt to alter the resistance. Take about 10ft. of the binding wire and connect it, in box B, across the terminals of the cores which are short-circuited in box A, so that there is exactly 8ft. 9in. of wire between the terminals, connect the short ends to the galvanometer leads, and in case (1) earth the other core.



Connect one lead from a 16-c.p. or 32-c.p. lamp to a "live" terminal, and touch the other lamp lead on the balance wire; the lamp will light and the galvanometer will give a deflection. Arrange two men standing on carpet or other insulation to hold the wire loop clear and slide the lamp lead along the wire till the galvanometer points to zero. Then, if, necessary, a closer balance can be made by holding the lamp lead in that position and using a key in the galvanometer circuit, and again sliding the lamp lead about the wire $\frac{1}{16}$in. at a time, and noting the direction in which the galvanometer tends to swing when switched in. Having found the exact zero position, mark or cut the wire there and measure shorter piece from mark to terminal; if this is found to be 27$\frac{1}{8}$in., the position of the fault will be $27\frac{1}{8} \times 2 = 54\frac{1}{4}$ yards from box B, at which the test was carried out. It is generally more satisfactory to afterwards repeat the test from box A, short-circuiting at B and taking midway between the two points indicated as the exact position of the fault, as this practically cancels any small error in measuring the length of the cores or of the short-circuiting links. The accompanying diagram readily shows the connections.—A. P. McD.

Answer to No. 735 (*awarded* 7*s.* 6*d.*).—The writer has had great success in locating faults on a given length of triple-concentric or concentric lead-covered cable by means of the method described later. To localise a fault on a large network to a length of main between two disconnecting boxes is often no easy matter, and it is impossible to say what is the best thing to be done without a knowledge of the particular circumstances of the case. Where the distributors are fused the blowing of fuses should indicate the section on which the fault exists. Supposing, however, that the fuses do not blow, or that the fault is an earth, the writer advises splitting up the network into two or more portions, as may be convenient, each portion to be fed by a separate feeder, with, of course, a middle-wire feeder if the main feeders are not triple-concentric or three-core. Then the fault will show on one or other portion by the current passing through the feeder ammeter connected to the faulty section. Transfer a portion of the network on which the fault is indicated on to one of the sound sections, and see if the fault goes with it. By continuing this process the trouble can be brought down to one length of distributor. To find the position of a fault on a length of main between two disconnecting boxes the writer uses a small motor-generator, such as is used for charging individual cells of a battery. The motor side is wound for the supply voltage, and the generator is made to give, say, 50 amperes at from two to ten volts. Such a machine can easily be taken about in a hand-cart and handled by a couple of men.

Having disconnected the faulty length of main, the little generator is put down alongside one of the disconnecting boxes, and the motor is coupled, through its starting switch, to one of the live mains in the box. The generator is coupled by a pair of short leads (with a portable ammeter in one) to the terminals of the cable to be tested. If the fault is a short between two cores, then the generator is coupled to these two cores and run up to such a speed as to give a convenient reading on the ammeter. The volts across the two cores must then be measured at each end of the main by means of low-reading voltmeters (cell testers are very suitable). If the fault is of very low resistance, no reading will be obtainable on the far end of the main. It will be seen that the pressure between the cores at the end remote from the generator will be due to the drop across the fault, so that this reading divided by the current passing at the time will give the resistance of the fault, which we require to know before we can determine the position of it. Having noted the current, C, and the volts, E, at the generator end of the cable, and also obtained the resistance of the fault, make the same test from the other end, calling the current C_1 and the volts E_1. Now, the



distance of the fault from each end must be proportionate to the resistance of the cable from each end to the fault. Referring to the figure, the resistance of the cable (lead and return) from A to the fault is $\frac{E}{C}$ – resistance of fault, and from B resistance is $\frac{E_1}{C_1}$ – resistance of fault.

To take as an example a test the writer made, which proved to be correct within a foot in a total length of 285ft.

On testing at A, current = 20·5 amperes at 2·5 volts, and volts at B at same time = 0·3. Therefore, resistance of fault = $\frac{\cdot 3}{20 \cdot 5}$ = ·0146 ohm. Resistance of two cores from A to fault = $\frac{2 \cdot 5}{20 \cdot 5}$ – ·0146 = ·1219 – ·0146 = ·1073 ohm

On testing at B, current = 25 amperes at ·55 volt. Resistance of two cores from B to fault = $\frac{\cdot 55}{25}$ – ·0146 = ·022 – ·0146 = ·0074 ohm. Therefore, distance of fault from A = $\frac{0074 \times 285}{\cdot 1073}$ = 19ft.

There seems to be no reason why this test should not be

Digitized by Google

applied to case No. 2 supposed by "R. V. M." The test current should be put through one of the short-circuited cores and back by way of the lead sheathing.

Case No. 3 should be dealt with in the same way. The writer has used this method of testing to find an earth on the outer of a triple-concentric lead-covered cable, and it should be just as applicable to the third case mentioned by "R. V. M." Of course, in these tests for earths it is supposed that the lead is either continuous or is well bonded at the service and other boxes, if any. Also, of course, before making the test, all consumers on this length must be disconnected at their fuse boxes.—S. A. C.

[N.B.—Will "S. A. C." kindly forward his name and address.—Ed. *E. E.*]

Answer to No. 735 (*awarded* 7*s.* 6*d.*).—The various resistance methods are, in the opinion of many engineers, impracticable and unsatisfactory. Conditions rarely favour the transportation of a testing laboratory. As hinted at in the question, many testing methods that look well on paper fail lamentably in practice. In order to locate the position of a fault, it is a very common procedure to burn it out, and by noting smoke at the manholes to determine more or less approximately the source of the trouble. This is rather a drastic method, and may lead to more burning than is desirable. Although it has been said that the best instruments which can be employed to find an earth are the pick and shovel, the "cut and try" method, unless used

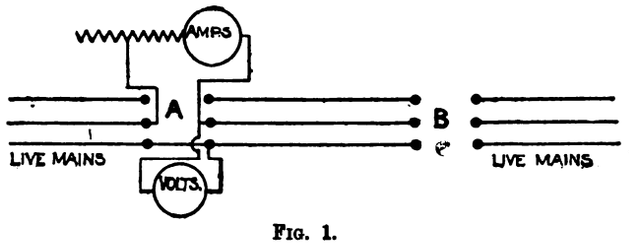


Fig. 1.

with great caution, is apt to be expensive. Very good results are often obtained by means of noting the deflections of a small compass carried over the surface of the ground under which lies the conductor. If a current of eight to twelve amperes is sent through the cable, and this current is reversed in direction every few seconds, the compass will show by its deflections ceasing where the

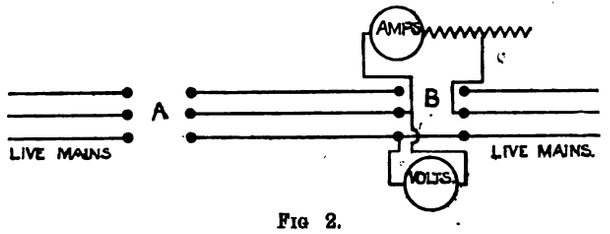

Fig 2.

fault is located. The induction method is also much used in connection with a telephone. A coil having about 500 turns of small wire, of such a shape that a long base is presented to the ground, is wheeled or carried over the top of the cable. A telephone being inserted in the coil, any alteration in the induced current in the coil is evidenced by the clicking or humming of the receiver. Thus one is able to more or less closely fix on a fault in a hidden conductor.

A very suitable method for finding faults as mentioned in the query would be by taking fall of potential when a current flows through the faulty cable. Take Case 1—two cores short-circuited. Figs. 1 and 2 show the connections. A and B are the manholes, or junction boxes, between which lies the fault. By means of the adjustable resistance the current is kept the same at each end. Let the distance between A and B = l; distance between A and fault = x; then distance between B and fault = $l - x$. In each case the drop in volts will vary as the resistance through which the testing current is flowing. Therefore, if d_1 and d_2 be the readings at A and B respectively,

$$\frac{x}{l-x} = \frac{d_1}{d_2}$$

$$x\,d_2 = d_1\,l - d_1\,x$$

$$x\,d_2 + d_1\,x = d_1\,l$$

$$\therefore\ x = \frac{d_1\,l}{d_1 + d_2}.$$

Case 2.—If it is a "dead earth," the same method will be obviously applicable, and it is very unlikely that the earth will be distributed far along the cable. At any rate, it is most improbable that the leakage between copper and earth will be so spread along the cable as to interfere practically with the test.

Case 3.—Send a measured current from each end, using an artificial earth for the return. Thus the two readings may be obtained.

Notes made while the mains are being laid, such as positions or joints, crossings, etc., are invaluable to a mains superintendent. Also, after mains are laid, a watchful eye should be kept on all road operations, and any abnormal readings of feeder ampere-meters noted. A competent mains man will often be able to almost fix on the faulty spot before testing operations.—M. M.

Question No. 736.—A shunt-wound generator is running at 440-500 volts. It is found, upon the shunt field circuit, which is separately excited, being made to the 'bus bars, a series of flashes occur midway between the commutator bars, where the conductors are joined, and the bearing surface of commutator—in other words, between the insulating varnish and air-space of the bars. This takes place immediately the shunt field or magnet coils are excited, and periodically while running on load; also, again, on breaking the shunt circuit. The armature in question was thoroughly cleaned and repainted, so it is no question of carbon or copper dust, neither is it due to oil, etc. Note that the sparking takes place between adjacent coils. Yet the generator is able to run without any undue heating, and a good insulation resistance to earth is obtained. Give what you consider the probable cause of this.

Best Answer to No. 736 (*awarded* 10*s.*).—Such intermittent sparking or flashing between neighbouring commutator plates is a fairly common occurrence on high-voltage machines, and is generally quite harmless. In spite of the careful cleaning of the commutator, carbon and copper dust does lodge temporarily on the mica between the commutator bars, and forms a more or less complete momentary short-circuit between them. In low-voltage machines the voltage from bar to bar is too small to pass any appreciable current across these temporary bridges, but in higher-voltage machines sufficient current is sent through them to burn them out, and this burning out is the cause of the flashes noticed (each spark being lengthened out into a streak of light by the persistence of vision, as the commutator rotates).

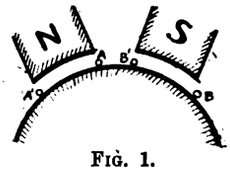

Fig. 1.

The fact that the flashing occurs more especially on switching the shunt in or out is due to an additional voltage set up in the armature sections by a transformer action between the shunt coils, acting as primary, and the armature coils, acting as secondary. This transformer action alone is unable to induce a voltage in the armature section anything like as great as that due to rotation, for the time taken for the flux to rise from zero to its full value after switching on (or to fall from its full value to zero after switching off), is usually a matter of many seconds, whilst the time taken to insert the whole flux per pole into an armature coil, by means of its rotation, is, at normal speeds, a mere fraction of a second. The fact that the flux changes whilst the coil rotates has the effect, however, of increasing the induced voltage above the normal during part of the time and reducing it during the rest of the time, whilst leaving the average induced voltage unchanged. This can be made clearer by the following numerical consideration. Let A B (Fig. 1) represent the two sides of an armature section. Between the times when the coil occupies the positions A B and A′ B′ respectively, the full flux (neglecting fringing) of the N pole becomes inserted into the coil and the full flux of the S pole is withdrawn from the coil. If the flux density is uniform

Digitized by Google

over the polar arc, the rate of change of the flux looped with the coil will be uniform, and will induce a constant voltage in the section equal to

$$\frac{\text{Flux per pole in C.G.S. lines} \times 2 \times \text{turns per armature section}}{\text{Time taken to pass from A B to A' B', in seconds} \times 10^8} \text{ volts.}$$

Call this voltage V. Next suppose that the shunt has only recently been switched on, and that the flux has only attained 90 per cent. of its full value at the instant when the coil is at A B, and reaches its full normal value by a uniform increase by the time that the coil arrives at A' B'. Then at the position A B the flux looped with the coil will equal ·9 F from the S pole, where F is the full normal flux per pole. When the coil has moved on past one-tenth of the polar arc the flux per pole will have to ·91 F, and the flux looped with the coil will be ·91 F × ·1 = ·091 F from the N pole and ·91 F × ·9 = ·819 F from the S pole. Or the change of flux looped with the coil during this interval is ·091 F + (·9 − ·819) F = ·172 F. If the full steady flux, F, had been attained, the change in flux in the same interval would have been ·2 F; ∴ the average volts induced in the position A B may be taken as $\frac{·172}{·2}$ V = ·86 V.

Next consider the other extreme point—viz., the instant when the coil is approaching A' B'. When the coil is one-tenth of the polar arc from A' B', the flux per pole will have attained the value of ·99 F, and the flux looped with the coil will be ·99 F × ·9 = ·891 F from the N pole and ·99 F × ·1 = ·099 F from the S pole. When the coil has actually reached the position A' B' the flux has reached its full value of F, and the flux looped with the coil is F for the N pole and O from the S pole, or the change in flux looped with the coil in this small interval is (F − ·891 F) + ·099 F = ·208 F—*i.e.*, the average voltage induced in the section whilst passing the last one-tenth of the pole will be approximately $\frac{·208}{·2}$ V = 1·04 V, or 4 per cent. above the normal. Though this voltage increase is small, the example will serve to show that a rise does occur if the flux is changing in value, and more especially just previously to the flux attaining its full value after switching on, or just after the flux commences to fall after switching off.

The actual value of the rise is determined by the relation of the time taken by a coil to pass a pole (depending on the speed of the machine) to the time taken by the flux in reaching its maximum value on switching on or in falling to zero on switching off (depending on the self-induction and resistance of the shunt winding, and on the value of the eddy currents set up in the solid iron of the magnets by changes of flux). It is, therefore, quite possible that in certain machines a considerable voltage rise might occur between neighbouring commutator bars, and this would tend to make the flashing across more frequent and more noticeable.—Q.

Answer to No. 736 (*awarded* 5*s*).—The flashing may be due either to an effect similar to that in induction machines, or to reflections from sparks at the brushes. On many dynamos, any alteration to the field or variation in load gives rise to a certain amount of sparking. This sparking being reflected by the varnished commutator lugs, might easily lead an observer to be under the impression that sparking was actually taking place between the lugs. Suppose, however, that the flashing is due to the first suggested cause. The brush-holders are at a considerable difference of potential, and these brush-holders, which are probably very close to the commutator lugs, act by induction on the varnished lugs Occasionally sparking may take place between brush-holders and the lugs of the commutator, persistence of vision making it appear as if the flashing actually took place between the lugs. It is quite to be expected that this phenomenon would have no appreciable effect on the working of the dynamo, nor on its insulation. The cause being due to the dynamo acting as a sort of influence machine, that which would be a good conductor for a static charge would give a good insulation test for a dynamo.—M. M.

Answer to No. 736 (*awarded* 5*s*.).—I assume that the sparking is caused by the following: (1) the armature of the generator has evidently a great number of turns per coil; (2) the magnetic field is very strong. If a circuit containing an electromagnet is suddenly broken, a spark appears at the points of rupture; this is caused by the collapsing of the magnetic lines upon the winding, which generates a sufficiently high E.M.F. to cause a spark. We have here a strong magnetic field cutting through a great number of turns of wire in a very short time. In the case of the generator, when the magnetic field is switched on, a large number of magnetic lines suddenly cut through the armature coils, which causes a sufficiently high E.M.F. to spark across the ends of the coils—*i e*, the commutator segments. When the shunt circuit is broken these lines are withdrawn, and again a high E.M.F. caused in the armature coils. This sparking will not take place when the field is steady.—W. DARLING.

SOCIETY OF ENGINEERS.

At a meeting of the Society of Engineers on Monday, the 5th inst., a paper on "Condensing Machinery" was read by Mr. William Edward Storey. After briefly mentioning a few of the condensing engines constructed in the seventeenth and early eighteenth centuries, the author showed how the desire to economise steam resulted in Watt's comprehensive invention, which introduced the separate condenser in a form very little varied to this day. He observed that the jet condenser, from its simplicity, was almost exclusively used until the demand for pure feed water became imperative and the surface condenser was introduced into steamships. The originating cause of the independent condenser was the high speed of modern reciprocating engines. A comparison of the relative advantages of different types of jet condensers shows the counter-current condenser to be more efficient than the parallel-current type, producing a better vacuum with reduced expenditure of power and smaller outlay for pumps. The barometric condenser, he observed, dispensed entirely with the air-pump, and he gave particulars of a large installation of such condensers in Manchester. A similar condenser, invented by Weiss, uses the barometric principle in conjunction with a dry air-pump. The design of water-pump best suited for use with counter-current condensers was stated to be the horizontal, in which type particular care has to be observed to prevent accumulation of air in the valve boxes. The question of pure feed water was the genesis of the surface condenser, the oil separator or filter freeing the water of condensation from the only impurity likely to have ill-effects upon the boiler. Jet condensers are more efficient, but cannot be applied in all cases. The author observed that the evaporative condenser enabled the advantages of surface condensation to be experienced where there was only sufficient water available for boiler feed purposes. Its chief drawback is the fouling of the cooling surface by sedimentary deposit. For tubular condensers the best arrangement for the tubes was stated to be the vertical, which gives better drainage for the water condensed on the surface and leaves the latter more efficient. Central condensing plants are used where many different units of steam-engines are installed, and are generally operated by their own steam-engines or by electric motors. At Deptford condensing plant for 10,000 h.p. of engines is erected on the roof. It consists of cooling towers, surface condensers, air and circulating pumps with their own high-speed engines. In conclusion, the author observed that the difficulties met with in dealing with condensers for winding and similar intermittently working engines had still largely to be solved, but were now receiving much attention.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

QUESTIONS.

745. A direct-current generator of 500 volts, for use on a three-wire system, is fitted with an automatic balancing arrangement, consisting of a choking coil fed, *via* slip rings, from two points on the armature windings, the middle point of the choking coil being connected to the neutral 'bus bar. Can you give the theory of its action in balancing the pressure of the two sides of the network?—DELCEF.

746. A 300-kw. Ferranti alternator (2,100 volts, 50 cycles, single-phase) is excited by a shunt-wound Elwell-Parker machine rated at 100 volts and 60 amperes, rope-driven from the main shaft. The exciting current varies from 40 to 60 amperes. Several times during the last 18 months this machine has dropped her exciting current under various load conditions, picking it up again after a short interval on one or two occasions. Careful examination for loose connections, slipping of the ropes, earths, or shorts on the exciter connections has failed to reveal any fault which would account for this behaviour. Moreover, the machine has invariably run satisfactorily on the next shift. The writer would be glad of an explanation of this phenomenon.—W. H. H.

747. How is it possible to predetermine, with anything like accuracy, the point at which a "synchronous" motor will drop out of step?—A. C.

ANSWERS.

Question No. 737.—Describe what you consider the best method of locating a middle-wire earth in any section of a network, giving sketches of same.

Answer to No. 737 (awarded 7s. 6d.).—Suppose the station battery is working in parallel with the generators, and both feeding into the network, a very easy method for testing the insulation resistance of the neutral or outer conductors without interfering with the supply is to make connections as shown in Fig. 1, where G is the generators, E the station

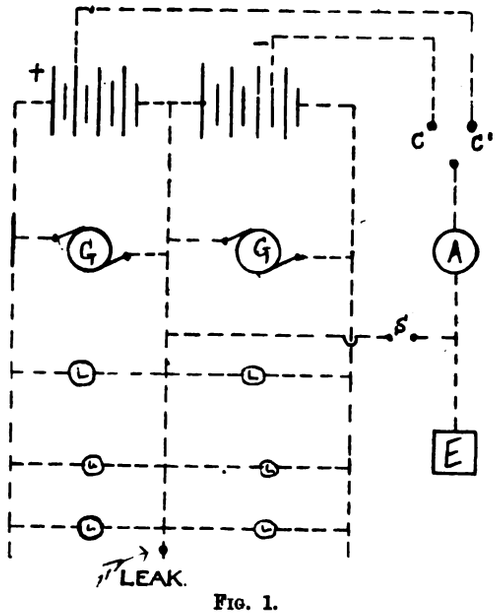

FIG. 1.

earth-plate to which the neutral wire is connected through the switch S, A is an ammeter which is connected through a two-way switch. The two contacts, C and C^1, are each connected to the third cell from the neutral connections of each side of the system. If the permanent earth is broken by the switch, S, and the two-way switch placed on contact C^1, and there is a leak on the neutral main, a current will flow from the three cells to E, back to the battery through the neutral wire defect. If the two-way switch is placed on contact C, you would get the same result, only the current would be in the opposite direction. This test will immediately show up any serious defect on the outer of the triple-concentric system. When you have found that there is a fault, you can then proceed to find it to a certain area. This can be effected very easily where there is a shunt central-zero ammeter, with a shunt between each neutral feeder, and the station neutral 'bus bar, to measure the current flowing through each neutral feeder. Of course, this test will have to be taken when there is no likelihood of the supply to alter for an hour. The permanent neutral earth at the station need not be interfered with during this test. Take readings, by means of the ammeter and neutral feeder shunts, of any current that is flowing between the neutral feeders and the station 'bus bar, and make a note of the direction of current by central zero ammeter, then earth the negative side of the system through an ammeter and resistance, commencing with a few ohms. Fig. 2 shows the arrange-

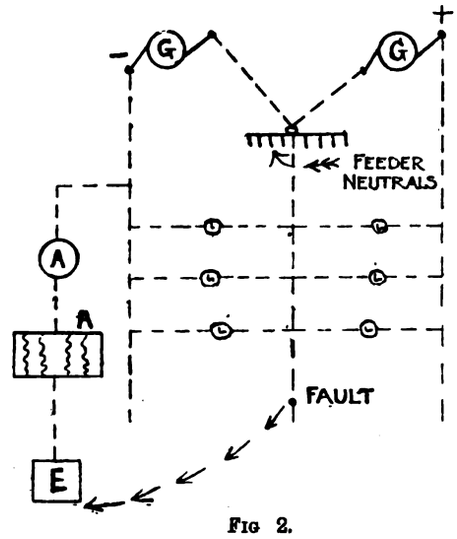

FIG. 2.

ment. The negative side is perferably earthed, for the reason that if for the purpose of testing it is necessary to put an extra strain on the insulation of either of the outer conductors, the positive should always be in a better condition to sustain it, because the insulation resistance of a negative conductor from earth is generally lower than positive. Having earthed the negative outer through the resistance, R, take the reading of the ammeter, A, and as quickly as possible take another set of readings of the feeder neutral-wire currents. These will no doubt be found to have increased over the previous readings, in proportion to the ratio of distance between each feeder and the defective main. If the system is a large one, with a number of feeders in parallel on the network, it may be necessary to increase the current permitted to pass to E through the resistance R, but it should be kept as low as possible to prevent the conditions of pressure on the main altering, so that the positive conductor of the system is put to a dangerous potential from earth, the Board of Trade limit being 250 volts, and to also prevent the possibility for seriously disturbing the defective main. After obtaining the second readings of the feeder neutral wire, it then remains to judge the locality of the fault. Having localised the fault to a certain district, you can then split that portion of the network into sections, making tests of each section until the faulty one is discovered. It may be possible to trace the defective main without disconnecting the sections in the defective area by means of a compass placed over the undivided neutral wire connections in the section boxes, and intermittently earthing one of the outers through a resistance, but where the current is available from the network the best test is Murray's loop test, which connections are shown in Fig. 3. V is a milli-voltmeter of the lowest possible resistance, containing a central zero and about 15deg. marked off on each side of the scale. R is the resistance frame, which consists of a porcelain insulated board, containing the resistance wire (about 20ft. 18 gauge copper wire), which is wound on insulators and constitutes the bridge. The wire should be stretched so that the exact length of wire at any point between its terminals could be easily calculated. The terminals should be of large dimensions, so that good contacts are got between the ends of the loop to be tested and the bridge wire. A bayonet lamp-holder socket is attached to one end of the

Digitized by Google

board, with suitable terminals, one for the supply wire, the other for the test wire. B is the faulty conductor. A is another, but without a fault, conductor of the three-wire main, of the same sectional area as B. H is a connecting piece of the same section as A and B, which should have a good metallic contact. First see that the pointer on the milli-voltmeter dial is directly over the zero point. Take wire G, make a contact with any part of the bridge wire, and watch voltmeter. Move the wire, G, along the bridge in one direction or the other until a point, say J, is reached, at which the voltmeter needle stands exactly at zero, and in the position in which it rested before the test wire, G, was used. When the needle is in its normal position, take notice of the exact point at which contact is made with the bridge, and measure the lengths between this point and each end of the bridge respectively. The position of the fault on the loop will be in a direct ratio with the different lengths obtained between the test contact and the two ends of the bridge, the fault on the loop, A B, being nearest to that end of the bridge which gives the greatest length between its end and the test contact.

Suppose test contact came 5in. from A and 15in. from B. Measure the total length of loop A B, and if the total length is 200 yards the fault will be $\frac{5}{20} \times 200$ from one end and $\frac{15}{20} \times 200$ from the other end, 20, of course, being the length of the test wire. The fault will, therefore, be 50 yards from one end and 150 yards from the other, and

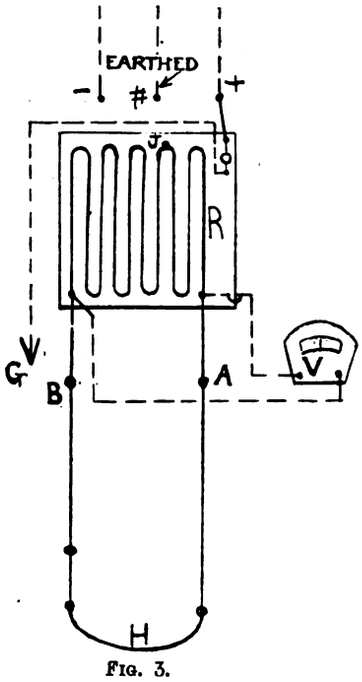

Fig. 3.

the fault will be nearest to that end of the loop which is connected to the longest length of bridge, which is B H; therefore, the fault would be 50 yards from B. The feeder neutrals are not shown in Fig. 2, but they may be assumed to be connected to different points of the network, terminating through ammeter shunt connections at the station 'bus bar.—J. P. S. (Hetton-le-Hole).

Answer to No. 737 (*awarded* 7*s.* 6*d.*).—Fig. 1 shows the arrangement employed in some stations to test a three-wire system of mains. Under normal conditions, the switch B is closed, thus connecting the neutral 'bus bar to earth through the ammeter, A_1, and light fuse. Should an earth occur on the positive or the negative of the system, the fuse is blown and the bar is connected to earth through the lamp, which is connected to the terminals of the fuse. In some cases a variable resistance is inserted in the circuit. To test the mains, the positive, neutral, and negative 'bus bars are earthed in turn by closing switches C, B, and A respectively. If a fault exist on the neutral, a current will flow through the fault, and will be registered on A_1, when either of the switches A or C is closed. Assuming the pressure between positive and neutral, and neutral and negative, to be equal, the adjustable resistance remaining unaltered, a current of the same value will flow through the fault in each case. Should a fault exist on either of the outers as well, on the positive side, say, the ammeter will register the sum of the currents flowing through both faults when the negative is earthed; and when the positive

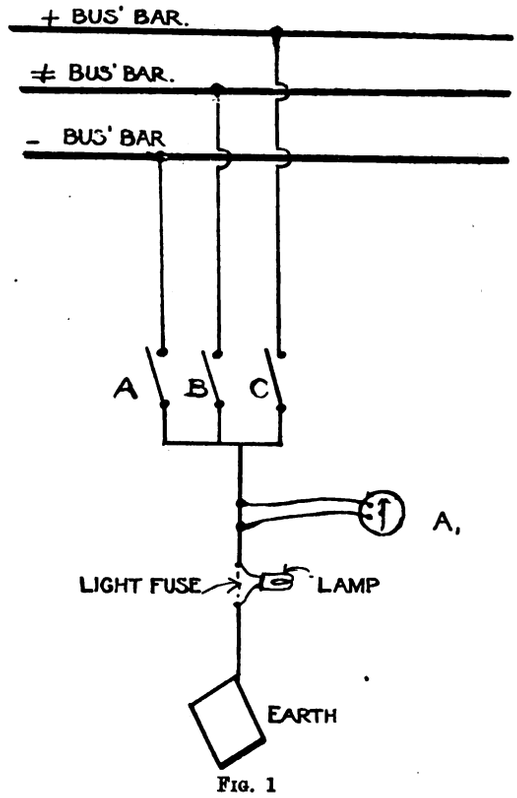

Fig. 1

itself is earthed, the current through the neutral fault only will be registered on A_1. If a fault exist on a consumer's premises, say between two arc lamps, run in series between positive and neutral, when the arcs are switched off, the fault may appear to be on the neutral—that is, the fuse may not be blown when the neutral is earthed, but when switched on the fuse will be blown, and the lamp will glow. If the positive and negative be successively earthed, the ammeter reading will be greater in the latter case.

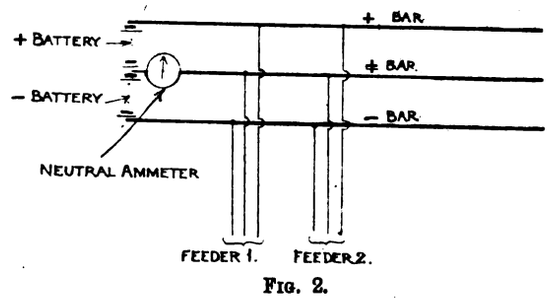

Fig. 2.

In Fig. 2 current is supplied to the 'bus bar from a battery, as is the case in some stations when the load is lightest. The neutral current, returning to or leaving the station, as the case may be, is registered on the neutral ammeter, and thus, when the switches A or C (Fig. 1) are closed, the reading of this meter, when the fault is a neutral one, will be altered by the amount flowing through the fault. To test for a neutral fault on the feeders, they may be successively disconnected at feeding points and 'bus-bar ends. If the fault exists on any of these, it will be removed when the faulty feeder is disconnected. In some stations it is possible to read the current in one or more of the neutral feeders at a time by connecting them through a special ammeter to the neutral 'bus bar. By thus connecting each neutral feeder in turn to the neutral 'bus bar, the other end of the feeder being disconnected from the network, the faulty feeder can be detected. Should the feeders be free of fault, the network may be divided into

Digitized by Google

two sections, one section being connected through the special ammeter, and the section with the faulty distributor detected by noting the readings of the neutral ammeters when the positive or the negative is earthed. Then by continually transferring a distributor from the faulty to the sound section, the fault will be transferred to the sound section with the faulty distributor. In this way the fault can be traced to a length of distributor.

An alternative method, where the above is impracticable, is to disconnect either of the outers and the neutral of a distributor and connect the remaining live outer and the disconnected neutral through a lamp, the neutral being earthed at the station. When the neutral which is faulty is connected in this way the lamp will glow. This method means the cutting off of supply from consumers connected to the distributor under test. Another way of applying this test, when circumstances permit, is, instead of disconnecting one distributor at a time, to disconnect a section of the network. A lamp connected at one point of it, as above, will glow until the faulty neutral is disconnected from the section. To localise the fault in the cable, the following may be applied: In Fig. 3, K H is the faulty neutral, having a fault at F. M, N, O are live terminals. M is connected through a bank of lamps, R_1, and ammeter, A_2, to the neutral at H. Thus a current is passed through the fault to earth, the neutral bar at the station being earthed. Terminals, K G, at the other end of the cable are short-circuited and a voltmeter, V, connected to D and H, which will read the difference of potential between the fault and H. Let E_1 be the reading of V when a current, C_1, is passed through the fault. Let X be the resistance of

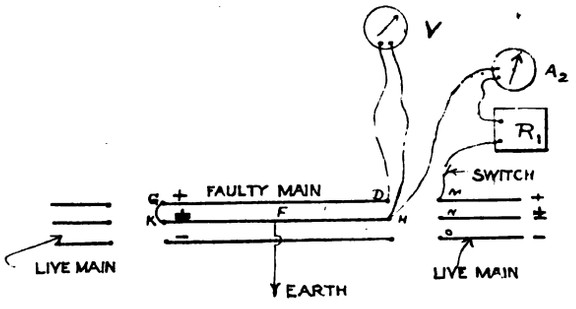

FIG. 3

F H; the resistance, R, of K H will be known. Then we have

$$\frac{E_1}{C_1} = X \quad \text{and} \quad H F = \frac{X}{R} \cdot H K.$$

Readings should be taken from the other end of the cables in the same way to check the value of X obtained as above. If E_2 and C_2 be the difference of potential and current in this case,

$$\frac{E_2}{C_2} = R - X.$$

Should two faults exist, the point F obtained as above would lie between them. Should the fault be on a house service connected to K H, the point F will be the position of the house service joint.—H. J. W.

Answer to No. 737 (*awarded* 5*s.*).—There are three general methods in use having for their purpose the localisation of faults. These are: the induction method, the fall of potential method, and one or other of the several forms of the "loop" arrangement. Provided the cables are unarmoured and not lead-covered, the induction method will, as a rule, be found most satisfactory. With this test an alternating or pulsating current is passed through the cable, and any alteration in the induced current in a portable coil noted by means of a telephone. The portable coil may conveniently consist of about 500 turns of No. 20, wound in the form of a triangle having a base of about 2ft. or 3ft. The coil should be provided with a laminated iron core. This coil is carried or wheeled as closely as possible to the ground immediately over the faulty cable, in order that the inducing effect may be a maximum. Fig. 1 is a diagrammatic sketch showing its application for locating a fault in the neutral of a three-wire system. At the station one of the outers is put to earth through an interrupting device and a resistance. The current is usually from eight to twelve amperes. Suppose, now, the exploring coil is carried over the faulty conductor, starting from the station. A clicking sound will be heard at the receiver until the coil comes over the fault. The sound will then cease, as the intermittent current does not flow in that part of the faulty cable which is beyond F.

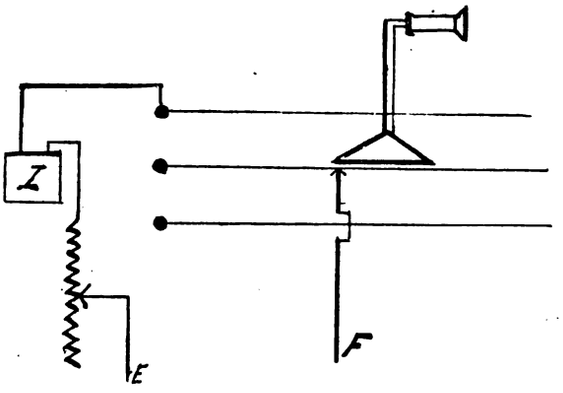

FIG. 1.

This test may also be made from any joint-box or manhole that may be convenient. In order to secure good results with this method, some practice is necessary; allowance must also be made for deviations in the path of the cable. The drop of potential method requires for its

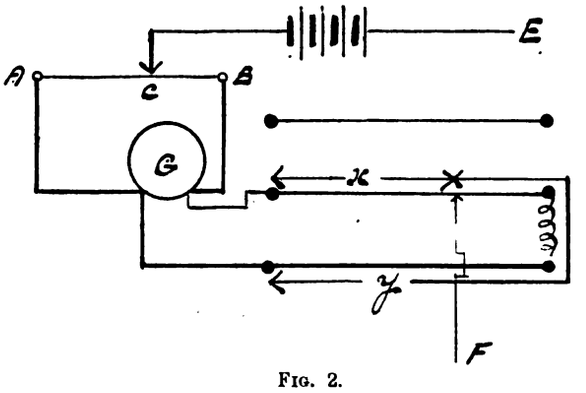

FIG. 2.

use delicate instruments, and rather troublesome calculations have often to be made owing to alterations in temperature. There are, however, many mains engineers who favour this particular method. When the cables are lead-covered or armoured, one of the loop tests will generally be found most reliable. With armoured or lead-covered cables, especially in dry situations, the leaking current does not necessarily leave at the fault and

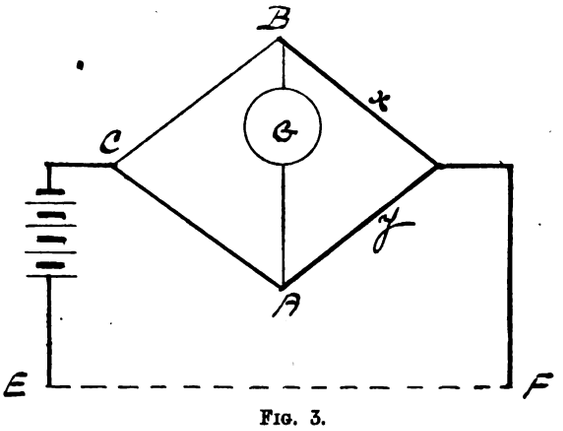

FIG. 3.

return by earth, but may first run some considerable distance along the metallic sheathing. In such cases the induction method often leads to erroneous calculations. Fig. 2 is a sketch of connections for localising fault on neutral. A B is a metre bridge (any piece of stretched wire of regular diameter and resistance will do equally well); C the adjustable contact of bridge; G, galvanometer—one of the outers is joined to the neutral at the distant

Digitized by Google

end to provide a return; x is distance to fault in one direction; y the distance in other direction. We here have the advantage of a null method when on making contact at C no deflection is obtained, x is readily found. Fig. 3 is a diagram showing test in the familiar "lozenge." From which we have, when there is no deflection:

$$\frac{CB}{CA} \propto \frac{x}{y} \quad \therefore x = \frac{y \times CB}{CA}.$$

—M. M.

Answer to No. 737 (*awarded* 5*s.*).—It is assumed that the system in question is capable of considerable subdivision by means of disconnecting boxes at street corners or elsewhere, and that the neutral under normal conditions is earthed at the supply station only. First proceed to divide the network (or section on which the earth is known to be) into a few portions which can, for the time being, be fed from one central point only. Before doing so it must be remembered that it is unwise to take out the neutral links only, as this may result in putting a few large consumers in series with one or two small ones across the outers, with obvious results.

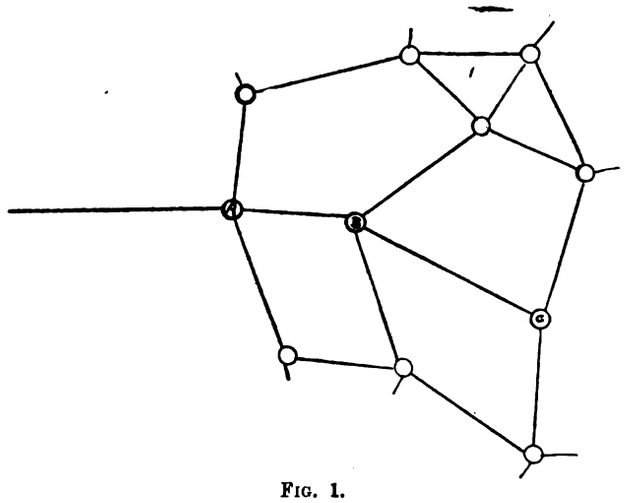

FIG. 1.

Suppose A (in Fig. 1) is the central point chosen, all other sources of supply to the section in the diagram being disconnected. Isolate one distributor, such as A B C, with its branch distributors, and test for an earthed neutral by making one outer alive and trying if a lamp will light from outer to neutral with the neutral link out. Repeat the test with each distributor radiating from A (each taken with its tributary sub-section of the network) until you find the one which gives a light with its neutral link out. Then take off one road at a time until you fail to get a light. This has now led you to the faulty main. Confirm this by testing the main as before, with a lamp from outer to neutral, making the outer alive from the remainder of the section which has now been coupled up again.

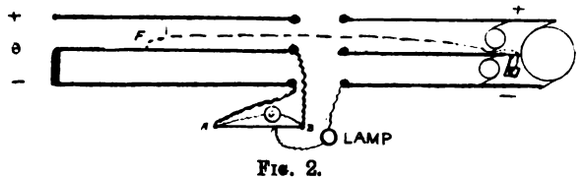

FIG. 2.

The next thing to do is to try the following loop test after having removed all consumers' fuses, or at least all those on one side of the system. Short-circuit one end of the main from neutral to one of the outers, and unless this be an absolute short-circuit it should be made by a piece of copper of definite length and section. Across the other end of the same pair place a length of 5ft. or 6ft. of platinoid wire (say No. 16, or thereabouts) stretched along a piece of casing (or a fault-localising bridge made for the purpose). At the two ends of this wire (A and B in Fig. 2) couple up a sensitive galvanometer. A wire is now connected through a 16-c.p. lamp to one of the live outers in the disconnecting box, and is slid along the platinoid wire until a balance is obtained. The sliding contact now divides the platinoid wire in the same proportion as the distance of the fault from the box bears to the total length of main (lead and return). In working out the result, account must be taken of the fact that the neutral is of different section to the outer, and allowance must also be made for the leads which connect the wire bridge to the main, and which should therefore be as thick and short as possible. Excellent results may be obtained by this method, the writer having frequently located faults by it within $\frac{1}{5}$th per cent.

Example.—The wire bridge is found to balance at a point 37·5 per cent. of its length from end B. The length of main, whose section is ·075, ·05, ·075, is 246 yards. The short-circuit is arranged so as to have negligible resistance. The size of leads used for coupling up is $^7/_{18}$, whose sectional area is ·0125 square inch. The two lengths used are each two yards long. We thus have the total length of main, reduced to a basis of ·05 square inch, made up as follows:

246 yards	·075	= 369 yards equivalent	·05
246 ,,	·05	= 246 ,, ,,	,,
4 ,,	·0125	= 16 ,, ,,	,,
	Total	= 631 ,, ,,	,,

37·5 per cent. of 631 = 236·5 yards. Deduct eight yards (the equivalent of two yards of $^7/_{18}$), and we find the fault to be 228½ yards from the box.—H. J.

Question No. 738.—Describe a practical way (other than by indicator card) of taking valve settings of Willans three-crank compound engine fitted with automatic expansion.

Best Answer to No 738 (*awarded* 10*s.*).—The Willans engines when supplied with variable expansion gear, whether operated by hand or automatically, are usually fitted with an indicator for the purpose of showing at what point the cut off is taking place. Possibly the indicator is not marked where the expansion is automatically varied. To do this entails exposing the trunk and variable expansion sleeve. Everything being made to jigs and gauges, and therefore all lines being alike, it will only be necessary to take the measurements from one line. The best way to do this is to disconnect the steam-top from the line nearest to the throttle valve. This involves breaking the joint between this and the steam-top of the next line, disconnecting the steam-pipe from the throttle valve, the throttle valve stem from the governor rod, and the link connecting the variable-expansion sleeves. When this has been done, take away the lower or cylindrical part of the steam-top, and replace the sleeve and cover, and reconnect the link. Cut some wooden distance pieces the exact length of the cylindrical portion taken away, with which to support the steam-top cover. Now place this line of pistons at the top of the stroke, and scratch a mark on the trunk against the top line of the port in the cut-off sleeve. Next move the line of pistons down until this scratch mark is lowered by an amount equal to one-tenth of the stroke. If the engine has been designed to cut off as early as one-tenth, you should now be able to cover the port in the trunk by the sloping edge of the port in the sleeve. This you will accomplish by twisting the cut-off sleeves by means of the hand lever at the flywheel end of the engine. This lever has a pointer attached to it, which slides in front of a segment, on which the position of cut-off can be marked. If at this one-tenth point the trunk port cannot be covered, then the engine has not been designed to cut off so early. Move the pistons down for another one-tenth of their stroke, and try again. When that tenth has been found at which the trunk port is covered by the sleeve, mark the position of the indicator for each tenth of the stroke for as many tenths as it will operate. Then mark further points of cut-off for the earliest and latest points, which will probably be at fractional parts of tenths. This completes the markings desired, and the steam-top can now be replaced. The measurements cannot be taken from the flywheel end line of pistons, as this steam-top is required for the support of the automatic link gear.—R. M. E.

Supplement to "The Electrical Engineer,"
DECEMBER 23, 1904.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

QUESTIONS.

748. Where several boilers are working together, is it common practice to fit isolating non-return valves instead of ordinary stop valves? State the advantages of doing so. Is there an automatic valve on the market which shuts off the steam supply when a pipe bursts? If so, describe it.—D. R.

749. A 200-h.p. three-cylinder gas-engine direct coupled to a dynamo is supplied with producer gas from a holder which is alternately filled and emptied. The engine will run steadily for hours at a time, but sometimes it will suddenly back-fire and pull up. The dynamo is cut out and the speed of the engine brought up again, and the dynamo is then put in again. The engine will then run steadily again. It has been noticed that the engine usually back-fires when the holder is commencing to fill. Give reasons for this. R. A. H.

ANSWERS.

Question No. 739.—A 50-h.p. gas-engine and a 40-h.p. motor, shunt-wound, are connected by belts and clutches to the main shaft of a factory, so that in the event of the gas-engine breaking down the motor may take the load running on town current at 460 volts. It is desired to instal two electric cranes requiring 12 h.p. each, and to feed them by driving the motor as a dynamo when gas-engine is running, and direct from town mains if gas-engine is stopped and motor has to drive the factory. What voltage would we likely get, and what is the best arrangement of switch-gear, etc., for changing over

Best Answer to No. 739 (*awarded* 10*s.*).—From particulars given it is not quite clear whether the dynamo could be speeded up so as to compensate for the loss of voltage. It will be seen that if this could be done, the whole arrangement would be greatly simplified. If, as a dynamo, the speed remained the same as when running as a motor, there would be a drop of probably 60 volts, but this would depend somewhat upon the design of the machine. It would, however, be an easy matter to put a voltmeter across the terminals, put starting switch to full "on" position, run up as a dynamo on open circuit, and see exactly what the voltage was. Assuming that no alterations are to be made to the existing pulleys and belting, and that as a dynamo the machine only gives 400 volts, the voltage of the town

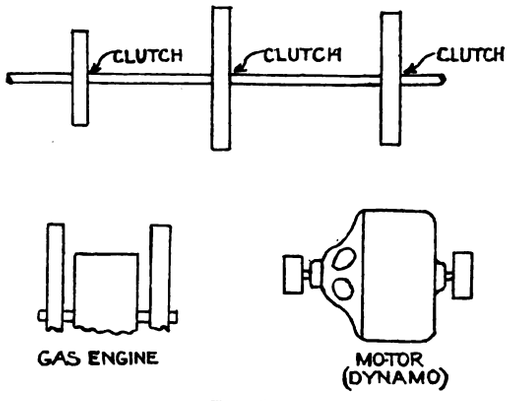

Fig. 1.

supply is 460; and if the electric cranes are to be run from that source for long periods, a considerable amount of current would be wasted if resistances were inserted in these circuits so as to enable the crane motors (wound for 400 volts) to be run off the 460-volt mains. There would also be the cost of the resistances. Four hundred and forty volt crane motors could be used, in which case they would run a little over speed when fed from town supply, and somewhat under speed when taking current from the factory dynamo. The latter method is the simpler of the two by far, and would be the more satisfactory, unless the disadvantage of the difference in speed of the cranes were sufficient to put it out of the question. On the other hand, it might be possible to fix a pulley on the opposite end of the motor (or dynamo) shaft, as well as an additional pulley and clutch on the shafting; also a second belt, and by suitably proportioning the diameters of these pulleys to so increase the speed of the machine when run as a dynamo as to obtain the required 460 volts. If this arrangement were adopted, 460-volt motors would be used on the cranes, and these would be working as efficiently when supplied from either source. This arrangement is shown diagrammatically in sketch No. 1.

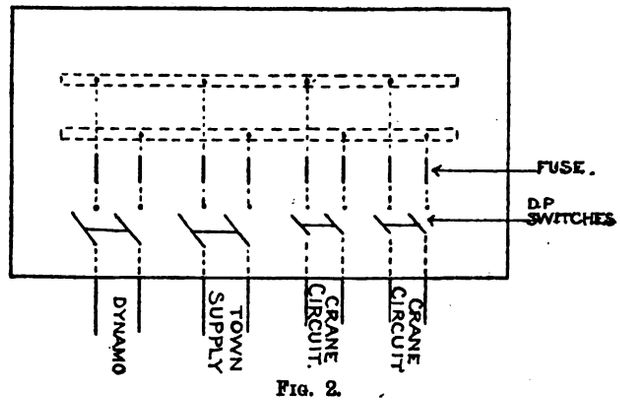

Fig. 2.

Sketch No. 2 shows a very simple switchboard arrangement, but one with which any of the following combinations for running can easily be made: (1) engine driving shafting and dynamo, the latter supplying current to the crane motors; (2) engine driving shafting, dynamo shut down, and crane motors running on town supply; (3) engine shut down, town supply driving crane motors and main motor, the latter driving the factory shafting. The existing motor-starting switch would, of course, have to be kept in the full "on" position when the machine was run as a dynamo, and if there is any likelihood of this being interfered with, it would be well to fix a switch which could be used to short-circuit the starter. The main switches would need to be handled with care, and to prevent careless attendants or unauthorised persons from putting the dynamo in parallel with the town supply it would be advisable to fix hinged pieces of fibre or vulcanite so as to project over the top contacts. These would require to be raised by hand before the switches could be closed.

With further reference to sketch No. 2, it will be noticed the main fuses are not placed on the live side of the switches. The 'bus bars could be either at the back of the board as shown or on the front, as preferred. Space is left on the upper part of the board for ammeter, voltmeter, etc., but for the sake of clearness these are not shown in the sketch. The idea of the arrangement is certainly a good one, as by its flexibility it would ensure the greatest possible immunity from stoppages of either the factory machinery or the cranes.—A.

Answer to No. 739 (*awarded* 7*s.* 6*d.*).—A shunt-wound machine will run as a dynamo or a motor in the same direction and with the same polarity, so it will not be necessary to worry about the polarity of the 40 h.p. motor, as the terminal which was connected to the positive main from the town supply will still be the positive terminal when the machine is driven in the same direction by the gas-engine. Having now settled this point about the polarity, it will perhaps be as well to consider what voltage we are likely to get across the brushes when the machine is run as a dynamo. This will depend on the design of the machine and on what point on the excitation curve we are working. If a curve be plotted for the magnetisation of a sample of iron plotting magnetic fluxes as ordinates and the values of the magnetising ampere-turns as abscissæ, we obtain a curve similar to Fig. 1. Now, a good modern machine is usually designed so that the poles are worked up to their saturation point—*i.e.*, so that the curve has

Digitized by Google

just got over the bend a little bit—as after this, although we might obtain a slightly stronger field, still it would necessitate many more ampere-turns being put round the poles. At the point at which we are working on this curve it will, therefore, be seen that a small change in the magnetising ampere-turns will practically not affect the strength of the field. The formula for the voltage generated in an armature is

$$E = \frac{n Z N}{10^8}$$

where E = voltage generated;
Z = total number of armature conductors;
N = total flux, and
n = number of revolutions per second.

Now in the case of our dynamo running as a motor, and *vice versâ*, we have Z and n both constants if we assume the motor alone drives the factory shafting at the same speed as the engine does, so we see the voltage generated in the armature will vary only with the flux. Assume that running as a dynamo with field separately excited this E.M.F. be 460 volts, the same as the town pressure, then when the machine is self-exciting there will at no load be a small voltage drop in the armature itself due to the field current passing through it; hence it will be seen that the voltage we shall get when the machine is run as a dynamo will be something less than 460 volts. This drop will make N drop slightly also, but this will be very small if the machine be working well over the bend of the excitation curve, and altogether we may expect a voltage on our bus bars from this machine below 460 volts by a small percentage. As the current generated is to be used for motors on cranes this will be immaterial, as it will simply make them run a little slower. Of course, when taking any load

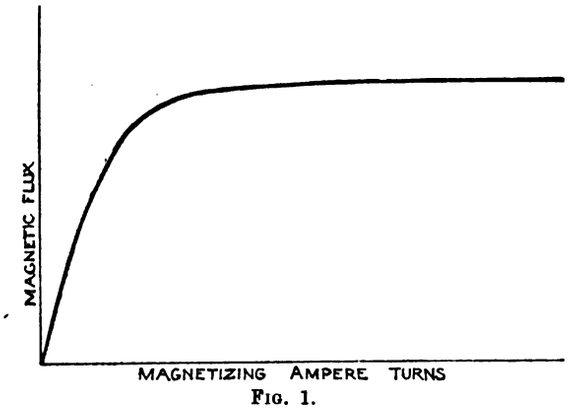

FIG. 1.

as a dynamo the voltage on this machine will still further drop. A way to overcome this total drop would be to increase the speed at which the machine is driven by driving it off a slightly larger diameter pulley on the main shaft, then when running as a motor the factory shafting will run slow, and it would be necessary to insert resistance in the shunt when it is running as a motor so as to speed it up, and then cut this out when it is running as a generator. This rheostat will be of no use when running as a dynamo as the voltage will be already low, and it will be impossible to increase the excitation by this means unless extra turns be wound on the field to be simply used when it is running as a dynamo.

The necessary connections I think suitable are very simple, and are indicated in Fig. 2, which speaks for itself. Suppose, first, all the shafting is being driven by the gas-engine and the cranes are not in use. To use the cranes it will be necessary to put in the clutch for the motor or dynamo and run this up to speed, and when voltmeter indicates 460 volts or as high as it will get, close the main switches for this machines, thus making the 'bus bars live and the mains to the two cranes. Now either or both of these can be run as desired. If it be now required to shut down the gas-engine, all that is required is to close the main switches for the town current on to the 'bus bars and then shut down the gas-engine. On closing these switches there will be rather a kick in the voltage, but as the current is simply to be used for motors this will not matter much, as it will only speed them up a little. To be able under these present circumstances to stop the mill shafting it will be necessary to open the motor switches; if one of these two be the present starter, it will be necessary to open this one, which, if a good make, will have a high resistance path to take the induced current on breaking the field. I think with this amount of explanation it will be clear how I should propose working this, and I may say this is about as cheap a method as any could be for running the machines in the way indicated in the question. Of course, the cranes themselves can be fitted with whatever style of controller it be desired, as that does not affect the question. In Fig. 2, W M is

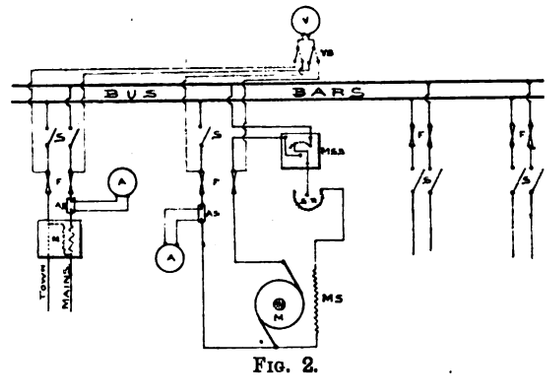

FIG. 2.

a wattmeter for the town supply, A S are ammeter shunts for the ammeters A, F are fuses, and S are switches. An extra switch can be put in the motor circuit on the same pole as the starter if it be desired, but I have left this out for the sake of economy. M is the motor which is to be run as a dynamo, and M S its shunt winding, S R the shunt rheostat for speeding it up which was mentioned before, M S S is the motor-starting switch, V is a voltmeter, and V S is a two-voltmeter switch for use with this, as it will save the price of a second voltmeter. If the kick in voltage and speed before mentioned in connection with parallelling the town supply on to the 'bus bars be objectionable, this might be done through some sort of resistance—*e.g.*, a water resistance—and then this be slowly cut out as the machine was being motored. Taken altogether, I think this method would prove to be satisfactory, and it would certainly not be costly.—E. R. ALEXANDER.

Answer to No. 739 (*awarded* 7*s.* 6*d.*).—Assuming the speed of the motor to be the same when driven as a generator, supplying current to the cranes, as when acting as a motor, the voltage at its terminals in the former case will be less than 460 volts, the voltage of the town supply. Taking the electrical efficiency of the motor as 97 per cent., the back E.M.F. generated in its armature will be about 446 volts. This would be the E.M.F. generated in the armature when driven as a generator, assuming the resultant magnetic field the same in each case. The voltage across the shunt winding, when acting as a motor, being 460 volts, will, when acting as a generator, be less. Consequently, the ampere-turns of the field system being less, the field will be somewhat reduced. For the

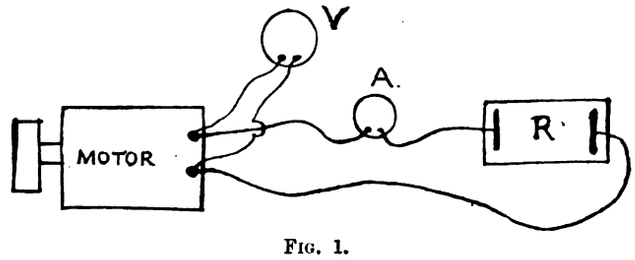

FIG. 1.

same armature current and equal excitation, the backward lead, if there be any, in the case of a motor needs be less than the forward lead in the case of a generator, owing to the effect of eddy currents and hysteresis. Therefore, the armature reaction will be greater in the generator. In this particular case, however, it may be less, as the armature current will be less than when acting as a motor.

Since the motor is already installed, and already coupled through the shafting to the gas-engine, why not run it as a generator, and note its behaviour while supplying

Digitized by Google

current under the conditions intended to work it under. Fig. 1 shows the arrangement for carrying this out. R is a water resistance, consisting of two sheets of lead partially immersed in water. The part of each under water may be about a square foot. Each sheet is connected to a pole of the motor. A is an ammeter placed in one of the leads; V, a voltmeter giving the pressure across the motor terminals. While the motor is being run up (driven by the gas-engine), the lead sheets are kept well apart, and after the maximum reading on V is obtained, the leads are moved toward each other until the ammeter indicates the current required by the cranes. Let C denote this current in amperes, and V_1 the reading on the voltmeter (in volts), and allowing 800 watts per brake horse-power for the cranes, C will be given by the formula

$$\frac{24 \times 820}{V}.$$

It would be advantageous to have the voltage at the motor terminals, when driven as a generator, as nearly as possible the same as that of the town supply. This might be obtained by increasing the speed of the gas-engine. As regards the connections required, Fig. 2 represents this diagrammatically. B_1 and B_2 are two 'bus bars connected to the town mains through fuses, F_1 and F_2, and switches, S_1 and S_2, all of which are probably in position. The supply company's meters and fuses are not shown. The motor is connected to B_1 and B_2 through the switches S_3

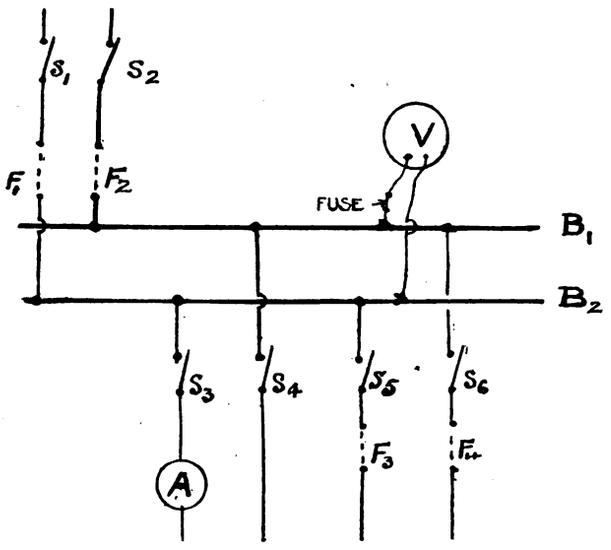

FIG 2.

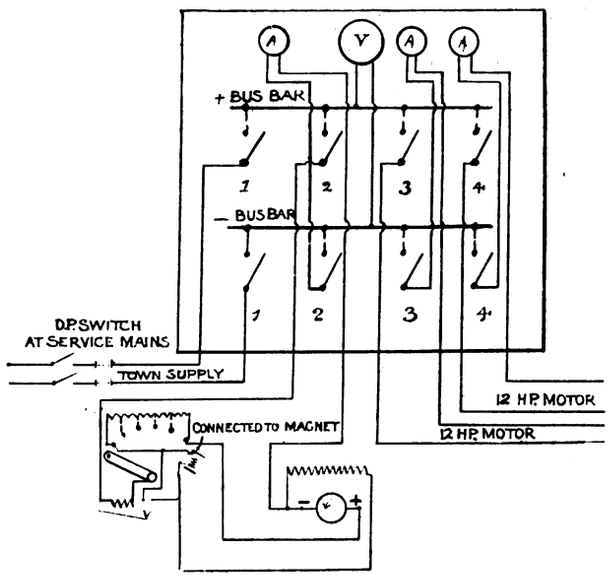
and S_4. The lead through S_3 has an ammeter, A, on it, which is to have two scales, one on either side of zero, so that when the motor is supplied with current from the town mains, the current will be read on the scale on, say, the left of zero. When the motor is supplying current to the cranes, the current will be read on the scale to the right of zero. The crane's circuit is connected to B_1 and B_2 through the fuses F_3 and F_4 and switches S_5 and S_6. If necessary, two separate circuits may be run instead of one. V is a voltmeter connected across B_1 and B_2. When all the switches are closed, current will be supplied from the town mains to the motor and the cranes. When the motor supplies current to the cranes, S_1 and S_2 will be open and S_3, S_4, S_5, and S_6 closed.—H. J. W.

Answer to No. 739 (*awarded* 7*s.* 6*d.*).—A shunt-wound motor is the most perfect example of a reversible machine—*i.e.*, if it is supplied by electricity it will produce power, or if it is driven by power it will produce electricity—and this without any alteration other than to find the correct position of the brushes. In electric motors the brushes have to be shifted slightly backwards against the direction of rotation. The brush bracket should be shifted as far as it will go in this direction without sparking, when the motor is running lightly. It will then take its full load without sparking, and without further shifting. In the case of dynamos, the brushes are moved forward with the direction of rotation, and set in the same way. The machine will have to be driven at a little higher speed than it would run as a motor at 460 volts to generate the same voltage. To prevent a confusion of change-over switches, I would suggest that a switchboard be installed with suitably mounted switches and fuses to meet the requirements of the Board of Trade and the local supply company's regulations.

The accompanying sketch will make itself clear. No. 1 circuit, town supply through an additional double-pole switch and fuses (which could be kept locked when not in use), would supply the 'bus bars, 40-h.p. motor, and the two 12-h.p. motors. No. 2 circuit, 40-h.p motor, when working as a dynamo, would now supply 'bus bars with electricity. Nos. 3 and 4 circuits, each 12-h.p. motors. A voltmeter placed across the bars as shown would give the E.M.F. of town supply and dynamo. An ammeter could with advantage be placed in circuits Nos. 2, 3, and 4, or, if expense is a consideration, one large ammeter with suitable readings could be used with a two-way plug arrangement. When machine is working as a dynamo, starting switch could be closed against hold on coil, and it would remain in this position so long as dynamo was excited. Starting switch shunt connections should be as shown, closed across motor itself, so that when motor is stopped by switch-handle flying back, shunt circuit is not broken suddenly. The action of the shunt is very much like inertia in moving bodies, and its effect in starting and stopping is very much the same, in that it will not start quickly, and it is dangerous to try and stop it quickly, as



an attempt to try to stop a large flywheel suddenly would do some damage —C. W. H.

Question No. 741.—A private telephone used in connection with a certain tramway system, to speak from the generating station to the different section boxes along the line, is found to work very unsatisfactorily when the cars are running, but works well when the cars have been stopped. The noise of cars can be heard quite distinctly, so much so that it is impossible to hear what is said. Length of track about seven miles; the telephone cables are laid beside the traction feeders, but in a separate trough, and parallel to the track. What is the best remedy to overcome this difficulty?

Answer to No. 741 (*awarded* 7*s.* 6*d.*).—Telephone lines along tramway routes must comply with the following conditions to give satisfactory results: (1) they must form a metallic circuit clear of earth faults, a single line with earth return being quite unsuitable; (2) the telephone wires must be twisted after the manner of ordinary flex throughout their entire length, otherwise there will be induction from the tramway feeders, etc., near them; (3) if the telephone wires form part of a multiple-core cable, as is often the case, other portions being used as pilot wires for rail drop, etc., they must be twisted in pairs before being stranded with the cable, or there will be induction between the telephone wire and the pilot wire forming the strand next to it.

The querist must test his telephone circuits for earth faults, and examine the cables to see that wires are twisted as described above. If they are not, he will have to instal new ones to get good results. The writer has laid many miles of telephone cables in the same trench with tramway

Digitized by Google

feeders without experiencing the least trouble from induction, it being quite impossible to hear the cars at all.—T. R.

Answer to No. 741 (*awarded 7s. 6d.*).—The noises heard in the telephone is perhaps due to leakage from the wires to the rails. If this is the case, it can easily be remedied. If no leakage exists, then the noises heard are caused by inductive disturbances—namely, electromagnetic induction, which is negligible where telephone circuits only are concerned; and electrostatic induction, which is very bad to get rid of. The theory of electromagnetic induction is, when a current is flowing in a wire, A, it is in the midst

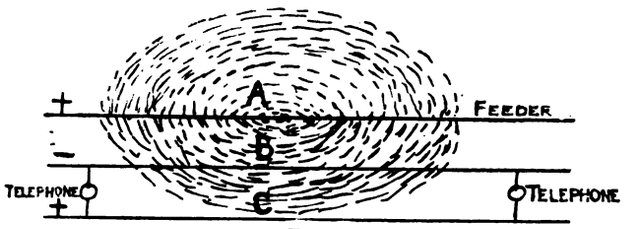


FIG. 1.

of a magnetic field. If this field cuts another wire, B, it will induce a current in B, only in an opposite direction to that in A. This is only a momentary current, but for any variation in the current in A there is an equal variation in B, but in an opposite direction. Fig. 1 shows the above, where A is a traction feeder, B and C the telephone lines. A current started in A may be detected in B, which would flow through each receiver (as indicated) and along C to complete the circuit. Therefore noises caused on the track rail may be heard on B line wire. The electrostatic induction theory is when a body, A, is charged with positive electricity, and another body, B, is brought near to it,

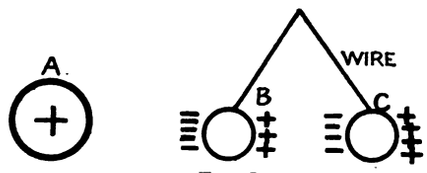

FIG. 2.

which is connected to a third body, C, further away by a wire, all the negative electricity in B and C is attracted to the side B nearest to A, and all the positive electricity passes to the side of B farthest from A, thence through the wire to C. This is shown in Fig. 2, which shows that by positively charging a body a current of momentary duration may be made to flow through a wire joining two other bodies entirely separate from it. The same thing is occurring in the telephone in question. If A is a traction feeder in which a current is flowing, and B the line wire of the telephone, C is the return wire, which also is connected

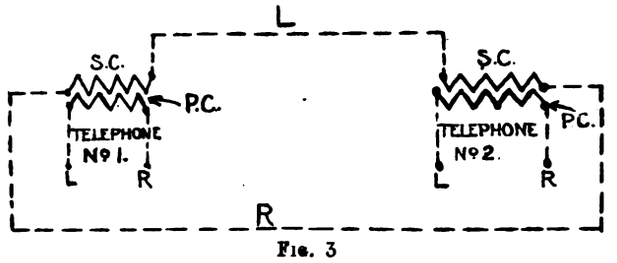

FIG. 3

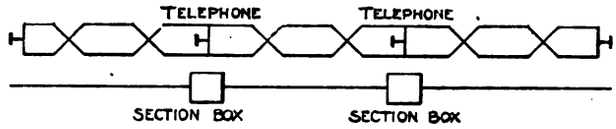
to B, through the telephones. If the circuit is metallic, and the telephone cables could be twisted, this would neutralise any electrostatic effects. If the telephone cables cannot be twisted, a very good remedy is to instal a transformer to each telephone. This has the effect of reducing noises, so that the speech will not be interrupted. The transformer should be of the closed magnetic circuit type, with the primary and secondary coils wound to as near as possible the same resistance, from about 150 to 250 ohms. Fig. 3 shows the connections to each transformer, where L is the line wire, S C the secondary coils, P C the primary coils to which the line and return terminals on the telephone should be connected, thus making the telephone and primary coil on metallic circuit. This arrangement will be found to work very satisfactorily, as electrostatic charges produce small currents of high voltage, and as the effect on the transformer is equal to E C, lost energy due to dissipation in heat in primary and secondary coils, also eddy currents and hysteresis in the core, the loud noises are lost in the transformer coils. I may mention that the telephones used should be of the carbon granular transmitter type, as they are the most suitable for long distances and where transformers are used.—J. P. S. (Hetton-le-Hole).

Answer to No. 741 (*awarded 5s.*).—The only effective way of dealing with the difficulty in this case is to eliminate as far as possible the disturbing inductive influence of the neighbouring feeders. This may be done on the same principle as that employed by the Post Office to protect its telephone lines from the disturbances set up by neighbouring telegraph wires on the same poles—namely, by twisting the lines round each other, or by the introduction of crosses at certain points on the route. If in the system referred to in the question there are two conductors running the entire length of the track, the telephones should be introduced in "bridge" across the lines at the several section boxes, the lines between the sections being twisted or crossed as



is found practicable. This provides the only really satisfactory remedy for inductive disturbances from neighbouring conductors, the effect on one wire being exactly neutralised by an equal and opposite effect on the other, with the result that a "silent" circuit is obtained.—A. F.

Answer to No. 741 (*awarded 5s.*).—The best way to remedy this will be to put a return wire beside the existing lead. The telephone has now, I expect, an "earth" return, and if lead and return are placed together, all disagreeable sounds will cease. The reasons are:

1. If two wires are placed parallel to each other, and one of the wires has a telephone receiver in circuit, the other is connected to an alternator or in circuit with a battery and vibrating circuit breaker. If the machine is started or the battery switched on, a humming sound will be heard in the telephone, due to the rapid variations of the current in the other wire. The reason why the two circuits influence each other is this: the wires lie close together, and when the current is switched on, the lines of force spread out in concentric circles, which cut through the second wire, inducing an E.M.F. and causing a current if the circuit is complete. When the circuit is broken the lines collapse, and again cut through the wire, thus causing a second E.M.F. acting in the opposite direction; in fact, whenever the current varies in the exciting circuit a corresponding variation takes place in the second circuit, but, however, if the lead and return are placed together, the lines of force cut through both wires at once, causing two E.M.F.'s, one in each wire and each equal in strength, acting in the same direction; therefore, they oppose each other and the telephone is unaffected. The single telephone wire lying alongside the rails will, therefore, be influence by the variation of the current strength in the rails, which take the place of the return cable to the generating station. The rails are always more or less dirty, and so imperfect contact with the wheels of the car is made. This will cause great variation in the current strength, and the telephone circuit will be affected as described.

2. Another cause will be the difference of potential at the opposite ends of the track, the telephone being "earthed" near each end of the track. I think the real cause is the mutual induction between each circuit, which can only be remedied by placing the lead and return wires of the telephone circuit together.—W. DARLING.

Supplement to "The Electrical Engineer,"
DECEMBER 30, 1904.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

750. Can anyone give results of a 12 months' working of an installation using Diesel oil-engines as prime movers, especially as regards the upkeep of this type of prime mover, and any trouble found in working the same?—W. T. W.

751. What is the cause of shrinkage of active material in Faure type negative plates with subsequent loss of capacity? Can capacity be recovered; if so, by what means —SHRINKAGE.

752. Describe what you consider the best method for cleaning the dust off boiler tubes of the Babcock and Wilcox type of boilers, especially where boilers are erected in a cramped position.—J. C.

ANSWERS.

Question No. 742.—It is common practice in continuous-current designing to take the permissible reactance voltage (per section of the armature winding) at a higher figure in the case of motors than in the case of dynamos. Is there any basis for this procedure in point of fact or of theory? Please discuss fully.

Answer to No. 742 (*awarded 7s. 6d.*).—The higher value is assigned to the reactance voltage per division of the *motor* armature winding, for reasons which can best be understood after a brief consideration of the factors determining the value in any case. As the reactance voltage is precisely of the nature of the back E.M.F. in a choking coil, produced, as it is, by the fluctuations of magnetic lines generated by the varying currents in the windings during the period of commutation, the value can be calculated by the formula

$$e_r = 2\pi n \mathrm{L C} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

obtaining the equivalent values of n and L as follows. To find n, divide brush breadth by the peripheral speed of commutator, so obtaining the time taken to reverse the current—or the equivalent value to half a period. The reciprocal of double this value will be n, the equivalent frequency. L is calculated by estimating the number of lines generated by one ampere in 1in. of the embedded conductors (in a slotted armature), and multiplying by the length of inches embedded and by the number of turns commuted together (if more than one). Dividing by 10^8 we have L in henrys.

Rothert gives the following formulæ:

$$e_r = 60 \times 10^{-8} \times \frac{\xi \times \mathrm{K}_w \times (l + 0{\cdot}1\ l_2)}{\mathrm{N} \times \mathrm{P}} \quad . \quad . \quad (2)$$

where ξ = number of turns per element of winding; K_w = output; l = length of embedded wires; l_2 = length of free portion; N = polar flux; P = number of pairs of poles; and

$$e_r = 105{\cdot}6 \times 10^{-8} \times \frac{\mathrm{Z}^2 \times \text{r.p.m.} \times \mathrm{C}_1 \times (l + l_2)}{\mathrm{K}} \quad . \quad (3)$$

where Z = total number of wires; C_1 = current in one conductor; K = number of commutator plates.

From these data we see that the value of e_r per section of winding varies directly as the number of turns per element, and inversely as the number of commutator plates (corresponding to the number of elements). An average value assigned in machines designed for carbon brushes is 1·2 times the voltage for commutator section for dynamos, and 1·8 for motors. This 50 per cent. increase is necessitated by the tendency of modern practice to make cheapness the governing consideration of motor construction, and to this end the number of armature slots and commutator sections are reduced as far as possible. This, of course, means an increase of the wires per section, or ξ in (2), and decrease of K in (3), the result being an increase of e_r, the value of the reactance voltage. The increase in the volts per commutator section is the prohibitive feature in applying this principle to dynamo construction.—A. M. L.

Answer to No. 742 (*awarded 7s. 6d.*).—The statement made in the question that it is common practice to take the permissible reactance voltage higher in the case of a motor than in the case of a dynamo, seems to be far from true unless more detail is given as to the rating of the respective machines. As a matter of fact, in a line of standard machines rated for continuous working with the same temperature rise, the reverse is the case, as will be readily seen from the following. With machines of small and moderate size, of recent design, say up to 150 b.h.p., or equivalent in kilowatts, it is the temperature rise which limits the output of a given armature. Now, in a standard line of machines, the flux used in a given armature would be taken the same, whether for use as a dynamo or motor, in order to use the most economical densities in the iron. Also, for the same terminal voltage, it is well known that the speed required when working as a dynamo is higher than the speed of the same machine as a motor. In fact, if V is the terminal voltage, R the resistance of the armature, C the current in the armature, the ratio of the speed as a dynamo to the speed as a motor will be for the same flux $\frac{\mathrm{V}+\mathrm{C R}}{\mathrm{V}-\mathrm{C R}}$, whilst for the same heating the armature current must be the same, so that the reactance voltages must also bear the same ratio, which shows that, with the conditions pointed out above, the reactance voltage is usually taken at a higher value in the case of the dynamo. Even in the case of large machines, in which the tendency to spark limits the output, there is no reason why a higher reactance voltage should be allowed when working as a motor.

Looking at the question from a practical point of view, we might argue that in the case of the dynamo there is an attendant who could rock the brushes, assuming that the position was not fixed, which is not the case with motors, which usually have to run quite unattended, so that again the statement in the question must be opposed. If a stronger field is used in one case, the armature current may be much higher without fear of sparking owing to the stronger field, as is the case with motors rated for intermittent working. For instance, motors rated for a temperature rise of 130deg. F. after one hour's full-load run will be found to have a reactance voltage from 30 to 40 per cent. higher than in motors rated for continuous working, at the same time having equally good working properties. But in this case we have altered the conditions in such a way as to make the comparison unfair. What "F. W. D." has probably done is to compare dynamos with a temperature rise of 70deg. F. with motors rated with 80deg. F. rise, both after a six hours' run, in which case his statement would be quite correct.—W. J. P.

Answer to No. 742 (*awarded 7s. 6d.*).—It is not quite correct to state that more armature reaction is allowed in a motor than in a dynamo, as it is only in shunt motors that any benefit can be obtained from the armature reaction, consequently it is only in the shunt motor that a greater armature reaction is permitted. The reason for this procedure is fairly simple. In a dynamo or motor the armature reaction is greatest when the armature current is greatest;

Digitized by Google

in the case of a dynamo the effect of the armature reaction in weakening the field is most acute at full load, and results in lowering the voltage of the machine, a thing which cannot be tolerated, especially when the output of the machine is required to be as great and efficient as possible. In the case of a shunt-wound motor, however, the weakening of the field due to armature reaction is beneficial, in that it assists to keep the speed of the motor constant, as follows: A heavy load is thrown on the motor; for a moment the motor slows down, this reduces the back E.M.F. and allows the impressed E.M.F. to urge more current through the armature, resulting in the increased armature reaction weakening the field, and allowing the motor to run faster again. The speed does not come exactly up to its former value, but very nearly so, as long as the load thrown on the motor is within its legitimate limits; the effect, of course, of load being indiscriminately piled on to the motor would be to pull it up. A little consideration will show that in the case of a series motor the same effect cannot be produced by the armature reaction as in a shunt motor, due to the fact that in a series motor the field and armature current either decrease or increase together, whilst in a shunt motor the field is entirely independent of the armature, and the effect of weakening the field current is not to weaken the armature current, but to increase it, and *vice versâ*. In the case of a compound-wound motor the armature reaction is treated in the same way as in a dynamo—that is, is kept as low as possible and the speed regulation obtained by correct design of the series turns, the shunt winding always controlling the polarity of the field. The reason, then, for allowing greater armature reaction in a shunt motor than in a dynamo is that in the case of a dynamo, a series, or a compound-wound motor the armature reaction is productive of nothing but evil, whilst in a shunt motor, if properly controlled, this reaction will prove of great benefit.—W. T. W.

Answer to No. 742 (*awarded* 7*s.* 6*d.*).—Although considerable difference of opinion has always existed among engineers with regard to commutation, it has long been recognised that one of the most certain ways of securing sparkless collection at the brushes is to make the number of sections in the commutator as great as possible. Specifications have been issued stating that for a given voltage the machine must not have less than a certain number of commutator sections. Hobart, in his excellent paper read at Glasgow in 1901, pointed out that although a large number of sections tended to make good commutation possible, the prime factor in the matter was the product of the reactance of the section under commutation multiplied by the current flowing through that section. To this product he gave the name of "reactance voltage." It will be seen that in any machine, dynamo, or motor, increase of load means also an increase in reactance voltage. It is common knowledge that many machines which run satisfactorily at normal loads, spark badly when overloaded. Practice points to a figure of about three for the reactance voltage in order to secure good commutation. If this amount be much exceeded, the brushes are likely to work badly. It is not that a motor possesses any inherent property enabling it to run satisfactorily with a high reactance voltage; the answer to the question propounded by "F. W. D." turns rather on the question of rating.

Motors are often rated at considerably below their maximum output; in such cases, therefore, the reactance voltage, which appears to be excessive when calculated for maximum current, is but normal under the usual running conditions. Another point also to be considered is that many motors under full load fall off in speed. Thus, although there is an increase in current, there is a decrease in the periodicity. Therefore, the lower periodicity tends to reduce the effect due to a rise in current. This is seen from the formula: reactance voltage $= 2\pi \sim l\,C$, where l = length of conductor in the short-circuited section, and $\sim$ = periodicity (while the coil is short-circuited the current in it has to pass through half a period). Variation in speed is most pronounced in the case of series motors; this type of motor rarely runs long at its maximum output. With an equal ratio of rating and load there does not appear any reason why the reactance voltage may be less in a motor than in a dynamo. The great advantage claimed by Messrs. Parshall and Hobart in designing a machine on the lines that reactance voltage is to be considered of paramount importance, is that by so doing commutation is independent of the fluctations in field strength. Armature action, or varying potential on the magnets, may so weaken the fields of a machine, that its power to effect commutation by a so-called "magnetic fringe" is nullified, and sparking ensues. The whole question of reactance voltage is one well worth serious study by the electrical engineer.—M. M.

Question No. 743.—I use five tons of zinc annually in the production of hydrogen for plumbers' use. When the solution is saturated with sulphate of zinc it is thrown away. Describe best method of recovering the zinc in metallic form by electrolysis.

Best Answer to No. 743 (*awarded* 10*s.*).—The electrolysis of zinc sulphate solutions is attended with considerable difficulty, and requires skilled supervision and special knowledge. Zinc is a metal so electro-positive, and needing so much energy for its reduction, that when aqueous solutions of its salts are electrolysed there is a tendency to produce hydrogen instead of zinc at the cathode. Beside this, from most solutions, including the sulphate, the metal is liable to be deposited in a spongy condition, unless special precautions are taken as to the acidity of the electrolyte, and as to the current density at the cathode, and so on. The working conditions have been investigated by Mylius and Fromm, and the results of their investigations have been published (*Zeitschrift für anorganische Chemie*, 1895, p. 144. In order to avoid as far as possible the evolution of hydrogen at the cathode, the electrolyte should not be weak; it should contain at least 10 per cent. of crystallised salt, $ZnSO_4 7H_2O$. Next, it should be neutral or only slightly acid. The solution mentioned in the question will require to be diluted if the zinc has been properly used in the first instance, and the solution will, under the same circumstances, also be near the neutral point. Thirdly, the solution must not be basic, and it must not contain any oxidising impurity.

The next point to consider is, will it pay to instal plant to treat, and incur expenses to recover, so small a quantity as five tons annually? The cost of the necessary electric energy can be computed within a reasonable margin of accuracy. The decomposition of zinc sulphate, represented by the equation $ZnSO_4 Aq = Zn + H_2SO_4 + O$, involves an expenditure of 106 kilogramme-centigrade-calories for each 65 grm. of zinc deposited, which corresponds with 2,564 horse-power hours per ton, or 12,820 horse-power hours for five tons, equal to 3,749 horse-power hours for deposition of five tons per annum, working 24 hours per day. But in practice the current efficiency will not exceed 80 per cent., owing to the unavoidable expenditure of energy in producing hydrogen at the cathode, nor will the voltage efficiency exceed 50 per cent., so that the practical combined voltage and current efficiency will not exceed 40 per cent. The commercial energy required will therefore be $\frac{3,749 \times 100}{40} = 9,372$ horse-power hours continuous working for 12 months. If the current for electro-deposition is supplied from a motor-generator at, say, 80 per cent. efficiency, the power consumed will be $\frac{9,372}{0{\cdot}8} = 11,715$ horse-power hours, or $11,715 \times 0{\cdot}746 = 8,739$ Board of Trade units. If this could be obtained from a public supply source at 2d. per unit, the cost of energy would be £39. 10s. per annum, or £8 per ton of recovered zinc. As the value of zinc is, on an average, about £22 per ton, one-third of the value of the recovered metal is gone in the cost of power alone if taken from public source and at the price named per Board of Trade unit. To this must be added incidental expenses to provide for wear and tear of the plant, depreciation, renewal of anodes (which must be of carbon, which is attacked in solutions from which oxygen is generated, as in this case), and also expenses of skilled supervision. For all this there is a margin of, say, £14 per ton, or £70 per annum. It is doubtful, therefore, whether the zinc recovery plant would be a profitable one. However, if it should be thought advisable to undertake the

Digitized by Google

work, the following additional information will, it is hoped, be of service.

It will not be found possible to deposit the whole of the zinc in the bath, because the electrolyte will be constantly increasing in acidity as the zinc is deposited. At the same time, it is not necessary that all the zinc in the bath should be deposited at one time, as the liquor, partly depleted of the metal, may be used for hydrogen generation again. The amount of zinc to be deposited will be 32lb. per day, and for this at 80 per cent. current efficiency, and working eight hours per day, the current necessary will be 240 amperes. The current density will be about 15 amperes per square foot. Consequently the cathode surface will be $\frac{240}{15} = 16$ square feet. A tank to hold nine cathodes and eight anodes, each 1ft. by 1ft., will give the necessary surface and density. Placing the electrodes 2in. apart, a vat 48in. long, 14in. wide, and 16in. deep will be about right. The voltage will be between four and six. The parallel system must necessarily, with insoluble anodes, be employed—that is to say, all the anodes joined in parallel to the positive pole of dynamo and all the cathodes in parallel joined to the negative pole. The electrolyte must be kept constantly stirred.—ELECTROLYSIS.

[Will the author of this answer kindly forward his name and address.—ED., *E. E.*]

Answer to No. 743 (*awarded* 7*s.* 6*d.*).—The figures given in this question show that 2cwt. of zinc are used in a week. Two hundredweight of zinc dissolved in dilute sulphuric acid would amount to about 6,000lb. of saturated solution of sulphate of zinc, supposing that the solution is fairly saturated and at normal temperature, when 1lb. of the crystallised salt would be dissolved by 2½lb. of water. To deposit 2cwt. of metallic zinc from this solution would require 85,000 ampere-hours, or a current of 1,420 amperes 60 hours a week. The E.M.F. of the current would be best at about three or four volts. The solution would be normally acid, and is a good conductor of electricity. According to Gore, the solution should be diluted with about an equal bulk of pure water to give a good reguline deposit. Having thoroughly mixed the solution and water, the temperature should be allowed, if necessary, to fall to 60deg. F., and then the specific gravity should be noted by means of a hydrometer, as there will be some little practical difficulty in maintaining the bath at the proper density or strength for giving a good reguline deposit. The anode should be a sheet of platinum foil. The kathode may be a sheet of zinc or any metal, or even carbon if preferred. I need hardly mention that sulphate of zinc is composed of zinc and sulphuric acid, and that the effect of the electrolytic action is to separate these two. There will, of course, be no difficulty in lifting the zinc out of the bath when it is deposited, but if provision is not made for also removing the sulphuric acid, obviously the solution of the bath will gradually become more and more acid, and then the sulphuric acid will dissolve the zinc as soon as it is deposited, and so none could be removed. This acid, when free, can be estimated by the usual methods given in chemical text-books, if desirable, but in the process of electrolysis there is little or no need for this, because we know that every 65oz. of zinc removed from the bath would represent 98oz. of sulphuric acid set free in the bath. Therefore, careful note should be made of the quantity of zinc deposited every hour, and quicklime in proportion should be added to neutralise the acid set free by the electrolysis. The proportion of pure dry quicklime would be 56oz. for every 65oz. of zinc deposited. The lime would unite with the sulphuric acid to form sulphate of lime, which being only sparingly soluble in water would soon settle on the bottom and could easily be removed when necessary. A little care and practice will enable the bath to be kept in good working order. Fresh sulphate of zinc solution must be added to supply zinc for deposition, but this need not be diluted with water as the first lot was, because the bath having been made up in the first place, all that is necessary is to maintain the standard as shown by the hydrometer. The quicklime, if dry, will take up water as well as acid, and so all three will be removed together, and if the bath is fairly shallow and has a good surface exposed to the air, evaporation will help to get rid of the water added with the saturated solution of sulphate of zinc from time to time. The powdered dry quicklime must be laid on the surface of the liquid in the bath, and must be stirred in so as to give it an opportunity to find and mix with the acid before it settles to the bottom. Sulphate of lime is a white powder, whereas quicklime is generally slightly coloured brown. Care must also be taken that too much lime is not added, because it would deposit the zinc as hydrated oxide. A piece of litmus paper dipped into the liquid should turn distinctly red to show that the bath is acid. If the above directions are carefully followed, there will be no serious difficulty in obtaining a good deposit of metallic zinc, but great care must be used in maintaining the condition of the bath, or trouble will certainly follow. The platinum sheet mentioned above is very expensive, but if carefully handled it lasts for ever. However, to save expense, and considering that sulphuric acid is present in considerable extent in the bath, I see no reason why lead should not be substituted. It would be cheaper, and should give good commercial results. There is no difficulty in obtaining zinc electrolytically. The difficulty is in maintaining the proper conditions of the bath.—F. G. A.

Answer to No. 743 (*awarded* 5*s.*).—The most satisfactory process for recovering the zinc from a solution of zinc sulphate is by electrolysis. The following method is economical and gives good results. The saturated solution of zinc sulphate is placed in the ordinary depositing trough, using as anodes either plates of carbon or sheets of lead. The cathodes should be made of sheets of zinc. In the electrolysis of zinc sulphate, zinc is deposited at the cathode and sulphuric acid is liberated at the anode; it is therefore essential that a conductor be used as anode that will not be affected by the acid, as neither carbon nor lead are affected by sulphuric acid. These are most commonly used, and, if pure lead is used, the zinc would be deposited at a slightly lower voltage than if carbon be employed. The reason of this is that the back E.M.F. between zinc and lead is not so great as that between zinc and carbon when they are immersed in a solution of zinc sulphate. The sulphuric acid set free at the anodes by electrolysis rises and floats in a diluted state upon the surface of the zinc solution. This may be collected by allowing it to overflow into a trough, and used again to produce hydrogen gas and zinc sulphate. In this way a complete cycle of operations is obtained. Thus (1) the sulphuric acid dissolves the zinc, forming hydrogen gas and zinc sulphate; (2) the zinc sulphate is run into the bottom of the depositing trough, where it is split up by electrolysis into zinc and sulphuric acid; (3) the sulphuric acid rises to the top of the liquid and overflows into a vessel, from which it is pumped into the first trough, together with the deposited zinc, thus completing the cycle of operations. As the acid and zinc used in producing hydrogen and zinc sulphate is continually being reproduced by electrolysis, there is no loss except in electrical energy. By the method described above, one kilowatt-hour or Board of Trade unit will produce, roughly, about 10oz. of zinc.—A. J. MARTIN.

Answer to No. 743 (*awarded* 5*s.*).—It is doubtful if there is any known satisfactory electrolytic method of recovering the zinc. There are, in the electroplating industry, processes and manipulations with regard to zinc which are more or less trade secrets, but the writer is not aware of any that would be suitable for the purpose of "G. W." To obtain zinc by electrolytic methods has been an attractive object, and has engaged the attention of numerous metallurgists, but so far as is generally known with but little result. One promising patent (German) consists of the following arrangement: The cathode comprises a series of zinc plates suspended in a long vat; these plates are parallel to each other and to the ends of the vat. Between these plates, boxes, or holders are placed, which carry the residues intermixed with a quantity of carbon or crushed zinc ore. These boxes are provided with perforated sides to allow free circulation to the electrolyte. Cloths are stretched below the plates in order to catch any particles that may fall from the zinc

Digitized by Google

plates. In order to obtain a connection for the positive pole, anodes are made by inserting metal rods into the mixture of residues and carbon contained by the boxes. "G. W." would be better advised to try and find a market for the residue than to attempt the recovery of the zinc. Failing this, he would more likely find it more satisfactory to filter the residue and crystallise out the sulphate of zinc. He should find little difficulty in disposing of these crystals to advantage.—M. M.

Question No. 745.—A direct-current generator of 500 volts, for use on a three-wire system, is fitted with an automatic balancing arrangement, consisting of a choking coil fed, *via* slip-rings, from two points on the armature windings, the middle point of the choking coil being connected to the neutral 'bus bar. Can you give the theory of its action in balancing the pressure of the two sides of the network?

Answer to No. 745 (*awarded* 7*s.* 6*d.*).—The voltage obtained from the slip-rings is, of course, an alternating one, and when connections are made to the choking coil a small lagging current will flow, just sufficient to magnetise it and choke back the applied alternating E.M.F. Fig. 1

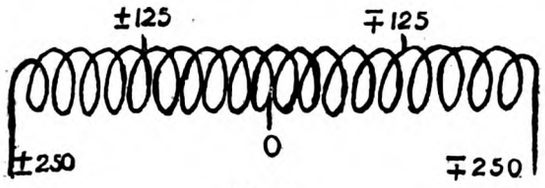

Fig 1.

represents the choking coil, and shows what voltages are obtained from different parts of the windings, the ends being marked ±250 and ∓250, meaning that while A is alternating between plus 250 and minus 250, B is at any instant at the same voltage, but with the sign changed. Similarly, at points one-quarter along the coil from either end the voltages may be represented as ±125 and ∓125. Following the argument further, we see that the middle point of the choker is zero at any and every instant—that is, it is always at a voltage midway between that applied to the ends of the coil; and, therefore, if the middle wire of the continuous-current system be connected to this point, it will be kept at a potential exactly half-way between the *generated* voltage of the machine, and the out-of-balance current will flow back to the machine *vid* the choker. It must be noted that the arrangement is not perfect, in that it provides a fixed zero point, and cannot be arranged to compensate for the extra drop in the mains of that side of the system carrying most current. The out-of-balance current returning to one side of the armature, as indicated in Fig. 2, even causes a larger internal ohmic drop on that

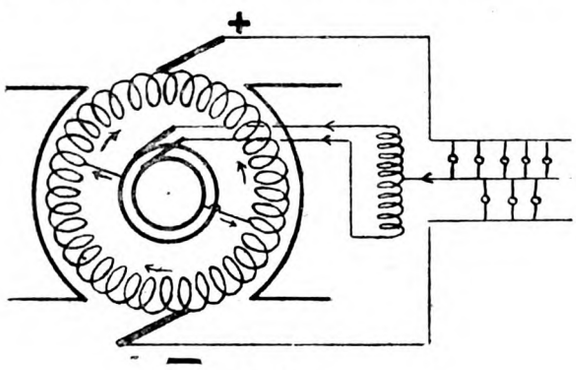

Fig. 2.

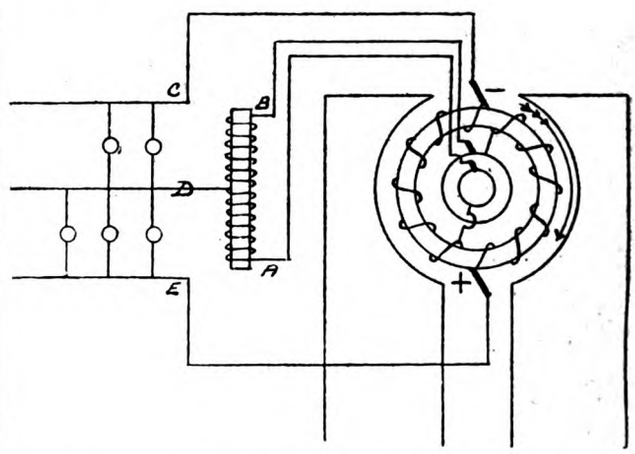
side of the machine, with the result that even the values of the terminal volts above and below the neutral point of the choker are slightly different. In designing the choker, a fairly high flux density may be used, say 60,000 or more, because of the low periodicity of continuous-current machines, generally less than 20, and as few windings should be put on as possible. The windings themselves should be provided to carry half the out-of-balance current, for the current divides equally on entering the choker. At first sight this would not appear so, for inasmuch as the points at which the current re-enters the armature are sometimes near to one brush and sometimes near to the other, it would appear that more current would travel by that path which brings it near to the brush taking the greater current (the positive brush in Fig. 2). But if more current flowed from the middle of the choker in one direction than flowed from the middle in the other direction, then the magnetism of the core would be disturbed and a back E.M.F. would be induced, which did not correspond to the applied E.M.F., with the result that an alternating current would flow in such a way as to restore the previous condition of things when the continuous current was dividing equally in the choker.—X. Z. Y.

Answer to No. 745 (*awarded* 7*s.* 6*d.*).—The idea of the arrangement is to provide a return for the out-of-balance current without trouble through sparking at the brushes. One method of supplying a three-wire system from one machine is to have a second pair of brushes on a diameter at right angles to the ordinary pair. These two extra brushes are joined together; it is evident they are at equal potential, and provide a return for the out-of-balance current by means of the neutral wire to which they are connected. Unless, however, the pole-pieces are specially shaped, this method is practically worthless on account of violent sparking. By employing a choking coil as described in the query, a path is provided for any out-of-balance current without this destructive sparking.



The accompanying figure is a diagrammatic sketch of the connections. The E.M.F. generated by the armature is a minimum at the negative, and rises to a maximum at the positive brush. In the position shown in the figure it will be seen that the inner slip-ring is at a higher potential than the outer. Suppose now that the side D E is more heavily loaded than the side C D, there is then a greater difference of potential between C and D than between D and E The out-of-balance current then flows from D to B, then to outer slip-ring, and by armature winding to the positive brush. As rotation proceeds and the connections from armature to slip-rings reach the horizontal position, A and B will be at equal potential, and the out-of-balance current divides equally. When the connections are vertical, A and B will be at maximum and minimum, the middle of choking coil being at mean potential. Any out-of-balance current will then flow to B, outer slip-ring, negative brush, and then down each side of armature to the positive brush. That A B must be a choking coil is obvious, as the reactance is necessary to prevent a large alternating current flowing through it from the brushes. The resistance of the winding on the coil must be low, in order to freely carry any out-of-balance that may be flowing in the middle or neutral wire of the system.—M. M.

[Other replies to Question No. 745 will be given in our next issue.—Ed. *E. E.*]
